**Anuria Caused by Corrosive Mercuric Chloride**—Balazs and Rosenak review the literature on the intravital dialysis of the blood and then describe their application of it in cases of poisoning with corrosive mercuric chloride. Following infiltrative anesthesia of the abdominal walls button-hole laparotomy is done at the upper median line and in the ileocecal region. Through each of these openings a perforated glass

cannula is introduced in such a manner that the end of the one cannula comes between the liver and the diaphragm and the end of the other into Douglas's pouch. In this manner a continuous irrigation of the abdominal cavity is made possible. The authors maintain that this method is superior to the mere filling of the abdominal cavity by means of puncture and by subsequent withdrawal. It is desirable to extend the irrigation for from three to four hours. Dextrose solution seems to be superior to sodium chloride solution as an irrigation fluid. Case reports indicate that the authors employed a 42 per cent solution of dextrose or an 0.8 per cent solution of sodium chloride. The temperature of the irrigation fluid was between 42 and 44 C. Peritoneal dialysis seems to be indicated in severe anuria or oliguria resulting from poisoning with corrosive mercuric chloride, particularly when uremic symptoms threaten. It is combined with other methods such as infusion and venesection.

**Influence of Throttling of Pulse on Blood Pressure**—Wolf and Aurin point out that the nonsurgical determination of maximal pressure is, except when oscillographic methods are used based on the principle of the closed artery. Objections have been made to this procedure by some investigators, who call attention to the fact that if the maximal blood pressure is determined on the basis of the closed artery, the tension of the arterial wall as well as the kinetic energy of the blood is included in the result obtained by this method of measurement. For this reason the authors decided to determine the influence of the throttling of the pulse on the type of pulsation and on the height of the blood pressure by means of a method of the registration of absolute sphygmograms, which avoids the division of the vessels and thereby leaves essentially unchanged the wall tension of the arteries as well as the movement of the fluid. The experiments were made on dogs and it was found that the throttling of the pulse causes considerable changes in the pulsation. Independent oscillations of the throttled section of the artery heighten the blood pressure values; the systolic maximal value becomes increased, the diastolic minimal value remains unchanged or is only slightly increased, the blood pressure amplitude becomes considerably increased. The independent oscillation of the throttled portion of the vein becomes especially noticeable following injection of epinephrine; it begins now earlier in the ascending portion of the systole, but as a result of this earlier development it causes no great increase in the blood pressure. The authors conclude from their observations that the throttling of the pulse causes a change in the results of the measurement of the absolute blood pressure values, which should not be overlooked when the human blood pressure is measured on the basis of the principle of the closed artery.

**Direct Determination of Blood Pressure**—Wolf and Kindler discuss the registration of the absolute sphygmogram by means of arterial puncture. They describe an apparatus that permits the direct measurement of the blood pressure in the cubital artery, and they give a detailed description of the entire procedure.

\*Torsion of Axis of Myomatous Uterus R. Schweigl—p. 1588  
\*Management of Delivery in Myoma Praevium O. Koller—p. 1592

**The Counting of Labor Pains**—Müller considers counting of labor pains according to Frey a method that permits a qualitative estimation of the process of delivery. The counting should begin after the rupture of the bag of waters, for certain rules can be applied only after this point is reached. Frey and his associates have determined the highest number of pains for the various stages of the labor process. They found that after these numbers have been exceeded a spontaneous delivery cannot be expected without threatening the life of mother and child. The author's observations corroborated Frey's statements to a large extent, and he concludes that the counting of the labor pains is a valuable and simple aid in the management of the process of birth.

**Torsion of Axis of Myomatous Uterus**—Schweigl gives the clinical history of a woman, aged 53, whose abdominal symptoms had been diagnosed as resulting from a myomatous uterus with necrosis and possibly torsion of the uterine axis. Signs of severe cardiac insufficiency predominated for a time and laparotomy could be resorted to only after the cardiac insufficiency had been counteracted. The operation revealed a large myomatous uterus, the axis of which had been turned 450 degrees, the twist being in the region between the body and the neck of the uterus. The operative specimen weighed 3.5 Kg. The author discusses the incidence of torsion of the axis of the uterus and the pathogenesis of the phenomenon. A review of the literature convinced him that the condition is comparatively rare. In discussing the development he cites Albrecht, who maintained that large intramural myomas during pregnancy and large myomas during the postmenopausal age are predisposing factors in torsion of the uterine cervix. He mentions Sellheim's theory explaining the torsion as the result of the persistence of a pedicled growth in a rotary motion that has been transferred from the body of the woman to the growth (lifting, sudden bending, dancing). This theory has been corroborated by Kustner. Payr, however, has suggested a hemodynamic theory of torsion, according to which stasis in the veins of the tumor may produce a turning movement. In the reported case, the causal factor was not determined.

**Management of Delivery in Myoma Praevium**—Koller describes three cases of myoma praevium, each of which required a different procedure: in one case an abdominal cesarean section with simultaneous enucleation of the two tumors from above, in another case perforation and extraction of the child with subsequent vaginal removal of the tumor, and in the third case abdominal cesarean section with subsequent removal of the tumor through the vagina. However, the author admits that a certain hesitation about the enucleation of the tumor from the puerperal uterus is justified. In the reported case it was permissible because of the superficial position of the tumor on the vaginal portion of the uterine cervix. Postponement of the removal of the tumors until after the puerperal period was inadvisable, because of the large size of the tumor, which caused an obstruction of the cervical canal and which in turn would have provoked a further complication by causing stasis of the lochia. The author considers an exception in myoma praevium the fact that in the other case the child had to be sacrificed. In the case under consideration this was unavoidable, because of the undetermined nature and site of attachment of the tumor and the impossibility to differentiate it from the fetal head, which stood at the pelvic inlet. The subsequent vaginal removal of the cervical myoma after the cesarean section, the procedure followed in the third case, is considered the least dangerous method, provided of course that the approach from the vagina is feasible. At any rate the three cases prove that general rules cannot be made and that individualization is necessary in cases of myoma praevium.

Deficiency Symptoms in Gastro-Intestinal Diseases—  
Goudsmit found that real avitaminoses (pellagra and beriberi) may occur in chronic gastro-intestinal diseases. They may be the consequence of an unbalanced diet or of an insufficient resorption of vitamins (conditional deficiency). It may be assumed that latent deficiencies presented a symptomatology of intestinal diseases. Four patients presented a syndrome of nail, tongue and reflex lesions that corresponded fully to the symptoms often seen in achylic anemia. The ectodermal syndrome in achylic anemia is probably caused by a faulty resorption of indispensable substances. Perhaps a deficient resorption of B is responsible. Consequently the ectodermal syndrome observed in four gastro-intestinal patients was considered a sequel of deficiency. Reflexes in gastro-intestinal diseases was recorded as an atypical form of the tongue nail reflex lesions. These deficiency symptoms are caused by faulty diet or by impeded intestinal resorption. The frequent occurrence of fat in the feces of patients presenting this syndrome may in connection with research done by Schuringa on fat-free diets indicate that a poor fat resorption is of great importance for the causation of latent deficiency in those suffering from chronic gastro intestinal diseases. In these patients attention must be paid to a correct diet as well as to fat resorption. Faulty fat resorption may be the sign of a chronic secondary gastro enteritis and the author considers it a more important factor in causing deficiency symptoms than an insufficient diet.

Study on Cause of Death in High Intestinal Obstruction  
on Chlorine Urea and Water E Schnoehr—p 1 Observations

**Cause of Death in High Intestinal Obstruction—In**  
experiments on rats, Schnoehr investigated whether the loss of  
chlorine of water or of both was the cause of death in high  
intestinal obstruction. He found that chlorine was lost from  
the gastro intestinal tract leading to hypochloremia and a  
definite lowering of the chlorine concentration in the skin, the  
liver and the kidneys. No alterations in the spleen, the  
muscles, lungs or spleen. The chlorine content of the brain  
was increased. The conclusion was drawn that the period of  
survival does not depend on the degree of hypochloremia and  
that there is no evidence that death was caused by concentration  
of chlorine in any particular tissue or that the decrease or  
increase or any specific level of chlorine concentration was the  
decisive factor in causing the death of the animal. The author  
found that the skin and the kidneys lost 30 per cent of their  
initial chlorine content, and the liver about 20 per cent. The  
quantity lost from the skin is equal to about one half of the  
entire loss. It also appeared that the skin lost its ability to store  
chlorine. The rise of the chlorine concentration in the brain is  
not specific for intestinal obstruction and there is no indication  
that it is capable of influencing the period of survival. When  
salt was administered to animals with high intestinal obstruc-  
tion it was found that animals with high intestinal obstruc-  
relatively higher than in the other organs. Animals treated  
with a 10 per cent solution of sodium chloride parenterally lost  
the same quantity of chlorine per unit as nontreated animals.  
The channels through which chlorine was lost differed how-  
ever, the treated animals losing far more through the gastric  
secretion and excreting far more through the kidneys than the  
nontreated animals. The administration of a 10 per cent solu-  
tion of sodium chloride had a pronounced diuretic effect. The  
author concluded that administration of a hypertonic salt solu-  
tion sufficient to make up for its loss is manifestly important  
in the prolongation of the life of an animal suffering from  
high intestinal obstruction. No relation could be demonstrated  
in rats suffering from high intestinal obstruction between the  
quantity of fluid lost the water concentration of the tissues  
and the length of survival. Dehydration therefore could not

be considered the determining factor in causing death. Administration of hypertonic saline solution does not seem to dehydrate an organism suffering from ileus. High values of blood urea were observed in rats with high intestinal obstruction. This azotemia responded to the administration of hypertonic solution with a definite lowering. But part of the azotemia remains in spite of the saline injections and shows no relation to the total chlorine content of the organism, the serum or urine chlorine or the diuresis and must therefore be considered to be due to an increased formation of urea that cannot be excreted as fast as it is produced. With intestinal obstruction an organism suffers on an average of an increased loss of great as during fasting, partly because of a loss of weight twice as fluid and partly because of an increased metabolism. Examination of the organs showed that the liver and the spleen suffered a rather striking loss about 40 to 60 per cent of their original weight. Since administration of hypertonic salt solution increased diuresis and lowered the azotemia its beneficial effect is attributed to an increased excretion of toxins. He concludes that death in high intestinal obstruction is due to toxemia.

**Fibrinogen Content of Blood in the New-Born**—Naeslund found that the fibrinogen content of the blood of healthy children is low at birth. It rises rapidly, however, and at the end of the first week is approximately twice the amount at birth. This rise in the fibrinogen content cannot be caused by the loss of water alone. In infants who showed an increased tendency to bleeding this rise in fibrinogen seems to fail, for in healthy children the fibrinogen values generally are lower than in the children of the same age. Moreover, the coagula-bility of the blood is considerably reduced in these children. The author assumes that the low fibrinogen content and the reduced coagulability of children with haemophilia neonatorum temporaria is probably a cause of the condition, although other factors such as a change in the calcium and fluoride content of the blood and the degree of oxygenation may play a part. Following a blood transfusion the amount of fibrinogen increases and so does also the coagulability. The author thinks that these factors may possibly explain the favorable effect of blood transfusion on children with an increased tendency to bleeding.

## THE PHARMACOLOGIST AND THE THERAPEUTIST

CHAIRMAN'S ADDRESS

JOHN H. MUSSER, M.D.  
NEW ORLEANS

The title of this section, the Section on Pharmacology and Therapeutics of the American Medical Association, is particularly appropriate. Pharmacology and therapeutics are scientific subjects closely linked the one to the other and fundamentally dependent on each other. Without the division of pharmacology, the division of therapeutics would be utterly and completely in a state of disorganization, and, without therapeutic application of pharmacologic studies, pharmacology would be a moribund or dead science.

Pharmacology is defined as a branch of science that has to do with drugs in all their relations. Therapeutics is defined as the practical branch of medicine dealing with the treatment of disease (Steadman). These definitions indicate that it would be platitudinous to remark that pharmacology could not exist without therapeutics or that therapeutics could have any reason for being or existing without pharmacology. The definition of pharmacology is a more comprehensive one than is that of therapeutics. Pharmacology presumably deals with drugs in all their relations, therapeutics merely with drugs as applied to diseased individuals. Pharmacology teaches exactly and scientifically the effects that a drug has on the systems, functions and reactions of the normal body as well as the diseased body, whereas therapeutics deals only with disease. Pharmacology may be likened to an exact science, one in which results may be predicted accurately and the anticipated effects predicated on that which has been done before. While not a science of the exactness of chemistry, mathematics or physics (and what biologic science is?) nevertheless the experimental results are definite, positive and clear cut in the majority of instances. A dose of belladonna or of its alkaloid atropine can be expected to bring about a definite effect on the heart, on the eye, on the circulation and on the secretions of the animal so injected when given in ordinary experimental doses. On the other hand, while atropine is given by the therapist for certain definite purposes, the therapeutic dose of the drug may not and probably will not occasion a clear-cut, definite picture of the action of the drug. The effect in the human being may be modified by many extraneous features and if that human being is a diseased individual it may be modified still further. These extraneous features of drug administration render therapeutics at best a quasiscientific matter.

If it is then admitted or acknowledged that pharmacology and therapeutics differ to a considerable extent and the one represents exactness, precision and accuracy, the other at least very often or all too often nebulosity, the fact remains nevertheless that the two are very closely integrated and correlated. Empirical therapeutics may exist without pharmacology. Unfortunately it has in the past, but happily nowadays pharmacology steps in to explain the *modus operandi* or the method of therapeutic action of drugs with due regard to scientific observation. The two branches of medicine exist, then, only by the grace of the one to the other. Without therapeutics there would be no purpose and no place for pharmacologic observation except as an occasional physiologic experiment or else to inform the mind of the intellectually curious. Definitely the two are interdependent.

If it is conceded that the two sciences, the one basic, the other subservient, are closely bound the one to the other, it cannot be said for one moment that the practitioners of the science of pharmacology and practitioners of therapeutics are in any way, form or manner closely allied.

The pharmacologist works in his laboratory, his scheme of procedure in an experiment is carefully planned and thought out. He can give all the time possible or needed to the experiment. The practitioner of therapeutics, the physician, labors under difficulties that the pharmacologist cannot realize or appreciate. The physician is called on to give immediate treatment in case of emergency, he must act quickly, he does not have the time and the opportunity to plan his line of attack carefully—something must be done immediately. His results cannot be anticipated as can those of the pharmacologist. He is dealing with a man possibly sick unto death and must act promptly.

As a result of the variations in the character of the work that the pharmacologist and the therapist do as a result of the circumstances under which each works, because the one is often a doctor of philosophy and the other always a doctor of medicine, because the one works with the human and the other on a lower animal, necessarily considerable divergence of results will be noted by the two observers, the one in his laboratory and the other at the bedside, when a comparable or a similar drug is given. Thus there has gradually grown up, I believe, a tendency for the one man to look with skepticism on the work of the other. The pharmacologist becomes irritated or disturbed by the failure of the therapist to put into practice the results of the pharmacologist's experiments. He feels that his results could and should be confirmed always by the man who is administering drugs. He loses patience with the man who cannot always accurately control his clinical experimentation. The therapist, on the other hand, is wont to criticize the laboratorian on the basis that he does

not know under what circumstances the practitioner has to do his work. He contends that the pharmacologist's work is not practical, that unfortunate and unhappy word so often abused by the clinical, he holds that the experimental animal is a very different animal from the human animal and he maintains that a laboratory test is not comparable to the test of the efficacy of the drug in man.

Utopia would be such a close working affiliation as existed between McKenzie, the great clinician, and Cushney, the equally distinguished pharmacologist. Of course it would be almost an impossibility ever again to get such splendid men to work together and collaborate as did these two. Cushney worked in McKenzie's wards, he saw the patients and he would observe in man the pharmacologic effects of the drugs administered. Equally satisfactory is the combination, in one man, of clinical judgment and experience with laboratory training. Cushing, the surgeon, is as much at home in the laboratory as in the clinic. His revolutionary pharmacologic work was the development of his observations in the clinic and in the laboratory. A man such as Cohn is a clinician who uses the precise methods employed by the man in the laboratory. Clinicians of this type have had a laboratory training, which all therapeutists cannot have. Certainly much can be done and will be done by the therapeutist who is laboratory minded and trained, a fortunate combination which few men will be found to possess. Every therapeutist who is not trained in the laboratory should have the help and advice of a pharmacologist, and every pharmacologist should have the opportunity of working with the human sick as well as with the experimentally diseased animal.

I have dealt with the self-evident fact that pharmacology and therapeutics are close relations. I would urge that the pharmacologist and the therapeutist be brothers in fact and not in theory.

1430 Tulane Avenue

## THE ENCEPHALITIS PROBLEM

JOSEPHINE B NEAL, MD

In charge of the Division of Applied Therapy, Department of Health,  
New York City Executive Secretary, William J. Matheson  
Commission for Encephalitis Research

NEW YORK

The encephalitis problem has many angles. It is easy enough to call attention to the points involved but practically impossible to present any satisfactory answers.

For nearly twenty years there have been outbreaks in various parts of the world of acute infections of the central nervous system, exclusive of poliomyelitis and meningitis. These have differed in seasonal incidence, in age distribution, in case fatality and in clinical manifestations. They have usually been described as some form of acute encephalitis or encephalomyelitis. In conjunction with these more or less spontaneous cases there has been a marked increase in the reports of encephalitis following vaccination, measles and other acute infections. While it is now known that encephalitis may run a mild course in the acute stage and escape recognition, the symptoms in the more severe cases are so arresting that they could hardly have passed unnoticed. It is not probable that clinical diagnosis has been any keener in the past two decades than

in the preceding years. It is safe to assume, therefore, that the encephalitis problem has reawakened during the past two decades. Historical accounts indicate that encephalitis is by no means a new disease and that doubtless outbreaks have occurred at intervals down the centuries.

The first question, then, may be stated: Why does encephalitis lie dormant for many years and then awaken to plague mankind? To this, no answer has been given.

TABLE 1—Tentative Classification of Acute Encephalitis

	Etiology
{ Epidemic encephalitis { Acute encephalomyelitis	Neutrople herpes virus?
Australian X disease	Transmitted to rabbits, monkeys, sheep, colt, etc., virus
Japanese type B	Filtrable virus pathogenic for rabbits
Encephalitis following vaccination	?
Encephalitis following infections	?
St. Louis epidemic	Virus pathogenic for mice and somewhat for rhesus monkeys

The second question may be formulated: What relationship, if any, is there among these various outbreaks and types of acute infections of the central nervous system?

Table 1 lists the more important of these.

This question can be answered only when a more definite knowledge of the etiology has been obtained.

It should be noted that one of the earliest groups of cases to be reported was that which occurred in France in 1915-1916 on the Western front and which was described as subacute encephalomyelitis by Cruchet, Moutier and Calmettes.<sup>1</sup> Other similar groups have been reported in Ohio by McIntyre<sup>2</sup> and by Stout and Karnosh.<sup>3</sup> Scattered cases have also occurred in various places. It has been considered by many that encephalomyelitis is a type of epidemic encephalitis. So far as I know the only instance in which a virus has been isolated in this disease is the W virus isolated by Gay and Holden.<sup>4</sup>

The etiology of epidemic encephalitis has not been definitely proved. The disease is generally believed to be due to a filtrable virus, and until the studies of the St. Louis epidemic were established it was more or less taken for granted that a single virus was probably the agent responsible for the disease. Considerable weight must be attached to the evidence that a neurotropic herpes-like virus is the etiologic factor in many cases, at least, of epidemic encephalitis. Several strains of this virus have been isolated and carried on in series.

Table 2 shows the instances in which this virus has been isolated.

It should be noted that these viruses are not identical in their various reactions. Dr. Holden has worked extensively with the herpes virus and with E. L. 1, W and J. A. These viruses all produce an encephalitis in rabbits but intradermal injections of J. A. and W regularly produce an ascending myelitis in rabbits, while intradermal injections of the herpes virus and E. L. 1 rarely produce this reaction. W and the herpes virus are very pathogenic for mice, while J. A. is not. A typical encephalitis in cebus monkeys has been produced

3 Stout, R. E., and Karnosh, L. J. Acute Disseminated Encephalomyelitis. J. A. M. A. 101: 667 (Aug. 26) 1933.

4 Gay, F. P. and Holden, M. Tr. A. Am. Physicians 48: 16, 1933.

by W Further studies of these viruses must be made to learn their exact relationship

In table 1 there is little that needs to be discussed While experimental work in the Australian X-disease showed that it could be transmitted to rabbits, monkeys, sheep and a colt, the virus was not extensively studied in relation to other viruses There is evidence that some of the cases were poliomyelitis But others were undoubtedly encephalitis, since one child developed parkinsonism in a short time and two others had mental disorders following the illness

From the Japanese type B encephalitis of 1924 several strains of virus were isolated by Takagi<sup>5</sup> and was called by him the "virus of encephalitis japonica" This was differentiated experimentally from the various herpetic encephalitic viruses

The etiology of encephalitis following vaccination and acute infections is best expressed by a question mark Are they caused by some recent change in the properties of the vaccine virus and the virus of measles, for example? Are they caused by the activation from lowered resistance of a latent encephalitic virus? (I have seen acute encephalitis follow toxin-antitoxin administration) Or are they caused by some symbiotic reaction of an encephalitic virus and the vaccine or measles virus? After all, the diagnosis of these forms of encephalitis can be made solely on the history Their clinical symptoms and the development of the chronic stage differ in no way from epidemic encephalitis

The St Louis epidemic of 1933 has the distinction of being the only outbreak in which the etiologic agent has been definitely established This is a newly isolated virus pathogenic for mice and less so for rhesus monkeys It has been demonstrated by Muckenfuss, Armstrong and McCordock,<sup>6</sup> Webster and Fite,<sup>7</sup> and Holden At one time it was suggested that it was the

that of the cases of the meningeal type of encephalitis that has been more or less common in New York since the fall of 1918 It is probable that in the future serologic tests will need to be extensively used in making a diagnosis of acute encephalitis

A third question of interest is this What is the mechanism of the development of the chronic stage of encephalitis?

When the chronic stage of the disease was first observed it was thought to be due to the effects of the inflammatory reaction of the acute stage An occasional patient is seen with residuals only of the acute stage In these patients, however, the disability remains the same or even shows a tendency to improve at least over a period of many years But this is not, I believe, the true chronic stage of encephalitis, which is usually a progressive affair, and which develops in most instances after months or years (sometimes from ten to fourteen years) of apparently complete restoration to health It is probable that from a third to a half of the patients who recover from acute encephalitis eventually go into the chronic stage Is this phase, differing so widely in most of its signs and symptoms from the acute phase, caused by the virus, which has remained latent, beginning to smolder? Sometimes the onset of the chronic stage seems to be precipitated by an acute infection or by an accident or mental shock, but far more often no such possible contributing factor can be found

As a subheading of this question, the not infrequent occurrence of acute exacerbations may also be considered I can think of one patient who has had three acute episodes over a period of eight years All of them were quite different in their manifestations and from all three there was a complete recovery Were they due to reinfections or were they caused by the flaring up of a latent virus?

A fourth question relates to the possibility of treatment I myself am quite optimistic in regard to effective methods of treatment being developed when there is more definite knowledge in regard to the etiologic agent That one can no longer think of acute epidemic encephalitis as being caused at all times by the same virus seems definitely established But if by serologic tests the infecting virus can be identified in a particular case, it should be possible by active immunization to raise the resistance of the patient so that his chances of recovery will be increased and the possibility of the development of the chronic stage greatly lessened And even if the patient has reached the chronic stage, it may well be that its further development may be halted by active immunization, especially if the treatment is begun early If this could be brought about, I believe that many patients in the chronic stage would show a considerable regression of their symptoms I believe this because many pathologists state that the symptoms are often out of all proportion to the lesions that are shown at necropsy Furthermore, several of our patients in a fairly well advanced stage of parkinsonism have been restored almost completely to normal, whether as a result of treatment or of spontaneous improvement, I cannot say And also the great majority of patients tell me that after awakening from a restless night's sleep there is a varying period in which they are completely free from any disability

For the past five years the Matheson Commission has been treating patients in both the acute and the chronic stage of encephalitis The method of treatment that has given the best results is that of attempting to immunize patients actively against the neurotropic her-

petic virus. A few patients in the acute stage have also received intramuscularly rabbit serum hyperimmune to this virus. While quite spectacular recoveries have followed the use of this serum, our series of cases thus treated is too small to permit definite conclusions to be drawn. The patients treated in the acute stage by serum or vaccine or both are being followed and eventually the effect if any on the development of the chronic stage will be known. Up to the present time no patients have begun to show signs of going into the chronic stage. In a few instances there are still residuals of the acute stage.

During the past year Gay and Holden have been preparing a vaccine consisting of the formalized virus, and so far the results with this vaccine seem to be particularly good. Our efforts at treatment are described in more detail elsewhere,<sup>9</sup> and time does not permit a more extended discussion here, but I may state that my associates and I are working with open minds and with an attempt to keep adequate controls.

A fifth question deserves serious consideration: What provision can be made for the hospitalization of patients in the chronic stage of encephalitis? There are tens of thousands of these patients in the United States most of them without the means to provide themselves with adequate care. Some are in state hospitals, some are in institutions for the care of the financially dependent, many are at home. Very few are enjoying the benefit they might derive from proper physical therapy, occupational therapy and symptomatic treatment. Hospitals especially designed for these patients are urgently needed. They are needed not only for the sake of the patients and their families but also because studies carried out in such hospitals would, in time, add greatly to the knowledge of this baffling disease.

## EPIDEMIOLOGY OF EPIDEMIC ENCEPHALITIS, ST LOUIS TYPE

J P LEAKE, MD  
Senior Surgeon U S Public Health Service  
WASHINGTON, D C

E K MUSSON MD  
JEFFERSON CITY, MO

AND  
H D CHOPE MD  
ST LOUIS

Final opinion regarding the exact nature of the encephalitis epidemic in St Louis City and County in the late summer of 1933 and regarding its pathogenesis and spread must await further study, although some information has been obtained that may give more definite trends to the estimation on these points.

### TYPE OF DISEASE

In recent years, encephalitis, like poliomyelitis, has been always present, and at every season, in communities of large size. A survey of the more important cities of the United States reveals that many of the cases currently being reported as epidemic or lethargic encephalitis lack the characteristics either of the disease as seen in St Louis in 1933 or of the disease as originally called lethargic encephalitis by von Economo or epidemic

encephalitis since Economo's first description. Some of these current cases prove to be some other condition in their further course, in others, on account of early fatality after being first brought to clinical attention or for some other reason, observation has been too limited to point definitely toward the diagnosis of encephalitis, while still other cases are diagnosed epidemic encephalitis on the basis of behavior disorders or juvenile parkinsonism without any clear history of an attack of encephalitis itself.

It would perhaps be well if all forms of infectious encephalitis were reported under item 17 in the International List of Causes of Death, without regard to whether they were lethargic or epidemic, leaving item 78, in diseases of the nervous system, only to infectious encephalitis, such as purulent encephalitis. The Economo disease though labeled "epidemic encephalitis" is not now, and never has been, epidemic at all as compared with the Japanese and St Louis outbreak of encephalitis.

Of the forms of infectious encephalitis that come into consideration in connection with this epidemic there may be considered first, and dismissed, the encephalitis due to the virus of acute anterior poliomyelitis. This is an exceedingly rare form of poliomyelitic infection when not combined clinically with a myelitis, so far as known, with the very questionable exception of the Australian epidemic of 1917 and 1918, it has never appeared by itself with epidemic prevalence.

The postinfection encephalomyelitis, which is characterized, as Perdrue has shown, by a patchy demyelination, occurs typically (but rarely) after measles, vaccinia, variola and varicella, and at a fairly definite period in the evolution of these diseases. Individual cases of postinfection encephalitis might be confused with the disease in St Louis.

In comparing this epidemic with the form of infectious encephalitis chiefly prevalent from 1917 to 1923, which goes by Economo's name (lethargic or "epidemic" encephalitis), and in comparing it with the Japanese type B, epidemics of 1924 and 1929 it will be shown elsewhere that there are distinct differences between the usual manner in which von Economo's encephalitis appears and the St Louis epidemic, but between the Japanese type of the disease and the St Louis type no clear distinction can be made. Even with the Economo disease, however, one might not be able to differentiate an individual case from the disease as it occurred in St Louis.

The outbreak that occurred in the summer of 1932 in Paris, Ill. is the closest precedent for the St Louis outbreak, clinically and epidemiologically they might be regarded as identical. Through the courtesy of the Illinois State Department of Health, the Paris physician, and particularly the local health officer, Dr W E Conklin, a search was made for cases in that city. Thirty-eight cases, similar in all respects to the St Louis cases occurred during the summer of 1932, 75 per cent of them during the three weeks from August 2 to August 22. This was an incidence of 433 per hundred thousand of population, over four times the rate in St Louis City and County in the following year, greater than the rate in any subdivision of the St Louis area of comparable size, and 60 per cent more than the rate in Kagawa the most severely affected province of Japan in the heaviest epidemic year 1924. Thirty-seven per cent of the Paris cases were fatal as compared with 20 per cent in the St

<sup>9</sup> Neal Josephine B. and Bentley I. A. Treatment for Epidemic Encephalitis Arch. Neurol. & Psychiat. 28: 897 (Oct.) 1932.  
Read before the Section on Preventive and Industrial Medicine and Public Health at the Eighty-Fifth Annual Session of the American Medical Association Cleveland June 15, 1934.

Louis epidemic, 60 per cent in the Japanese 1924 epidemic, and 63 per cent in the 1929 Japanese outbreak of 2,000 cases. As in St Louis and Japan, there was a great preponderance of cases in the older age groups in Paris, 82 per cent being in persons over 50 years of age. As to sequelae, also there was a notable lack of the distressing after-effects, which so frequently follow the Economo type of the disease that their occurrence in a considerable proportion of the cases is almost characteristic. In spite of the advanced age of many of the patients who had had a severe febrile attack with temperature exceeding 104 F and with marked cerebral involvement, very little increase of the deterioration to be expected with age was found in the Paris patients fifteen months afterward. In less than 2 per cent of the Japanese cases were after-effects detectable one year following the 1924 epidemic.

#### THE ST LOUIS OUTBREAK

It is believed that the basic epidemiologic data of the St Louis epidemic are fairly reliable. A check up, at the close of the epidemic, of homes not known to have been infected, covering sample neighborhoods in all parts of the city and suburbs, revealed practically no unreported cases.

There are two questions that occur in this connection. Did many mild cases occur that could not be diagnosed as encephalitis by any of the ordinary standards? From the random fashion in which the frank cases of the disease occurred in the community, this might be reasonable, yet actual search failed to reveal them in any significant numbers, either in other members of households where a frank case existed, or in households in which no case had been reported. Several of the St Louis physicians whose practice carried them into homes of the well-to-do believed that they saw during the summer an unusual number of mild, indeterminate illnesses, particularly among children, but the total number of such reports was not great.

It was noted that the cases in this epidemic, while lacking a single definite and unifying pathognomonic sign, were in general less varied in their symptomatology than the cases previously described under the term "epidemic encephalitis." The fact that hospitalization was the rule also made for more uniform and more accurate diagnoses. But a further question arises. Did the practice of using an increased cell count in the spinal fluid to determine the diagnosis tend to cause the inclusion of illnesses due to other causes or to exclude cases that should have been called part of the epidemic? It is not believed that any notable error crept in from this practice, in spite of the errors in sampling involved in the count of a small number of cells. The cases that responded to the disease in general symptomatology did show an increase in cell count at some stage of their course in almost all instances, and there was no considerable group of cases failing to fall in with the clinical picture of some one of the types of the disease that were called encephalitis merely on the basis of the spinal cell count. Cell counts higher than normal were much more uniformly found in this epidemic than in "epidemic encephalitis" in general. It is none the less to be recognized that the spinal fluid in typhoid, for example, and in some other diseases with pronounced cerebral symptoms may show pleocytosis independent of any idiopathic encephalitis.

The very first cases in the epidemic had their onset late in July and the epidemic practically ended with

October. A few straggling cases were reported from time to time during the winter months, none during the spring months. The outbreak began in St Louis County and subsided there first. Five hundred and seventy-seven cases occurred in St Louis city and 520 in the county, making a rate of approximately 100 cases per hundred thousand of population for the entire area, or 69 per hundred thousand for the city and 212 per hundred thousand for the county. Although this disease was new to all of us as a type distinct from Economo's encephalitis, its general epidemiology was so similar to that of poliomyelitis that we were able to predict, when the epidemic was only three fifths over<sup>1</sup> (656 cases having occurred out of a final total of 1,100) to a fraction of a per cent what the total incidence per hundred thousand of population would be (100), and with the same grade of accuracy the total case fatality (20 per cent). The fact that the final figures did coincide so exactly with round numbers was of course fortuitous.

Taking the city and county together, the proportion of cases that occurred in males was the same, 50.9 per cent, as the proportion of males in the total population. As to color, 9.9 per cent of the cases were reported in colored persons, who form 10.1 per cent of the total population. The disease apparently showed no preference as to sex, color or economic status.

The accompanying table shows the specific case incidence, the death rate per hundred thousand, and the case mortality rate for decennial age groups in city and county together.

*Case Incidence and Death Rates by Age Groups in the St Louis City and County Encephalitis Epidemic of 1933*

Age Group	Cases per 100,000 of Population in Each Decade	Deaths per 100,000 of Population in Each Decade	Case Fatality per Cent
0-9 years	54	4	8
10-19 years	64	3	5
20-29 years	65	3	4
30-39 years	73	6	8
40-49 years	119	14	12
50-59 years	169	56	31
60-69 years	285	109	38
70-79 years	464	204	56
80-89 years	419	235	80

This table shows a striking increase in the incidence of the disease with age, and an even more notable increase in the fatality with age. The latter tendency is not extraordinary in an infectious disease but is unusual to this marked extent, and the former tendency is practically unknown in infectious diseases except for the Japanese epidemics and the Paris, Ill., prototype of the St Louis epidemic. The combination of increasing mildness of the disease and less frequent recognition with descent in the scale of years from old age toward childhood suggests strongly the possible presence of very many cases of the disease in unrecognized forms among persons in the younger age groups, previously discussed.

No noteworthy difference was observed in case fatality (mortality per hundred cases) between cases occurring during the first part of the epidemic and those during the latter part. The fatality rate in the county was 17.5 per cent, as compared with 22.5 per cent in the city, a difference that was evident throughout all age groups in which the numbers were large enough to have any significance. This might be attributed to

# ST LOUIS ENCEPHALITIS—LEAKE ET AL

JOUR A M A  
SEPT 8 1934

slightly milder strains of the disease predominating in the suburbs in spite of a heavier incidence, to better resistance against lethality on the part of suburban dwellers, or to their securing medical attention and recognition in illnesses milder than would generally secure such attention in the city.

In fatal cases death came oftenest six days after onset, and in more than half within the first week.

Reliable data on the incubation period of a prevalent disease in urban communities are difficult to obtain. The many possible opportunities for infection make uncertain any conclusion from apparently connected cases. In this epidemic, however, only cities in the St. Louis section of the country showed any appreciable amount of infection with this form of encephalitis, and it was thus possible to assign boundaries to the infected region. Persons entering this region without previous contact with infected territory and later contracting the disease might reasonably be assumed to have had an incubation period no longer than the interval between their coming into the infected area and the onset of the disease. In the six cases of this sort that were recorded, the maximum incubation period thus ascertained was nine, twelve, fourteen, fourteen, fourteen, and twenty-one days, respectively. Other persons would have their first symptoms at some time after going from the St. Louis area into presumably uninfected surroundings. Here the incubation period we should suppose to be not less than the interval between the date of entering the infected area and the date of onset. In the seven cases of this kind, the presumed minimum incubation period was four, seven, eight, nine, eleven, thirteen, and fourteen days, respectively. According to this, one would expect about half a dozen cases to have incubation periods ranging at least from nine to fourteen days, and possibly from four to twenty-one days. Among a thousand cases a somewhat wider range might be expected.

The epidemic centered in St. Louis County and did not radiate far. About 150 cases occurred in Illinois, including the nearby cities across the Mississippi River from St. Louis, but the disease did not spread to Chicago, 250 miles away. Two definite Illinois foci did occur 75 and 100 miles from St. Louis and about twice as far from the Paris focus of 1932. Louisville, 250 miles from St. Louis, was the only other locality to the east to have any considerable number of cases.

To the west, scattered cases in excess of the normal occurred in Missouri and Kansas, with foci in Columbia, in and around Kansas City, and in St. Joseph, respectively 100, 230 and 250 miles from St. Louis. In the largest three of these foci, that is, the Kansas City area, Louisville and St. Joseph, a tendency was evident that was noted in St. Louis for the cases to be more numerous in the outlying sections than toward the center of the cities. In the Kansas City area there were 181 cases and in St. Joseph 45, with fatality rates of 23 and 30 per cent, respectively. The tendency toward selecting the older persons was noticeable, and the curve of the Kansas City outbreak, as to dates, was similar to that of the St. Louis cases.

In all places where the disease has appeared there has been a notable freedom from multiple cases in the same family or from other obvious contagion between cases. This is even more striking than in outbreaks of poliomyelitis, and some difference in that direction would be expected between a disease primarily of children and one of old people. As regards communi-

ties, the spread by contagion, presumably by human transfer, is obvious, but as regards individuals, the reverse is true with the disease established in a community, the matter of individual susceptibility, in which age played a part, appeared to be a much more important determining factor in contracting the disease than did contagion. In many of the households affected, the least mobile member, and the one stricken in contact with the outside world, was the one least in contact with the limitation of the disease in its typical form is also noteworthy. In none of the places to which the disorder spread did the outbreak prolong itself beyond the season during which it prevailed in St. Louis. There were no instances of two attacks in the same individual, but persons who had had an attack of poliomyelitis, even within a few years, were not spared from this disease.

The possibility of spread by drinking water was considered early in the outbreak. The fact that the city and the county municipalities received their water supplies from different pumping stations suggested a possible reason for the outbreak being largely a county affair. This possibility was promptly eliminated. There was no selective distribution of cases throughout city and county on the basis of milk supply, no dealer or dealers having a disproportionate number of cases among patrons.

The sharp limitation of the epidemic to the warm season of the year, and the lack of obvious connection between the cases as to contagion, water supply, food supply or milk supply, suggested at once one of the major objectives of the epidemiologic inquiry, namely, the possibility of transmission by insects. Entomologic investigation pointed to mosquitoes as being the most probable vector if there was an insect vector. No other biting insect, not even *Stomoxys calcitrans*, the biting stable fly, was likely to have a flight range long enough and breeding places so situated as to account for the wide and fairly rapid spread of the disease. The summer was an exceptionally dry one, and though replies to specific inquiries varied, it was generally believed that mosquitoes were worse than usual.

Aside from the studies on the virus and clinical studies, entomologic investigation was the first laboratory phase of the joint inquiry. It was conducted by a corps of workers of the United States Public Health Service. Laboratory facilities were provided by the Oscar Johnson Institute of Washington University, and special humidity and temperature rooms were placed at their disposal by the Missouri Botanical Gardens. Later these investigators were joined by a group from the United States Army with special facilities for *Aedes* experiments.

Attempts were made to inoculate monkeys and mice by the bite of mosquitoes that had been allowed to feed on encephalitis patients at various stages of the disease and allowed to bite the experimental animals at various periods after the initial feedings. Initial feedings were also made on inoculated monkeys and mice. Parts of the lots of presumably infected insects were also ground up at various times and inoculated into monkeys and mice. The three species of mosquitoes on which chief stress was laid in the experiments were *Aedes aegypti*, on account of the ease with which this insect may be handled experimentally, *Anopheles quadrimaculatus*, on account of the presence of malaria clinically and thus host having been found in the district concerned, and *Culex pipiens*, which was the common mosquito of

the region and, in spite of the difficulty in handling for experimental purposes, was the only species that could reasonably be incriminated as the possible vector in nature for this outbreak.

All the tests were negative.

On account of the relatively low percentage of success with monkey intracerebral inoculations (only 40 per cent) under the most favorable experimental conditions, it was believed that only human experiments would show the possibility of contracting the disease through the bite of a mosquito under natural conditions. For this purpose the governors and the health commissioners of the states of Mississippi and Virginia allowed certain of the convicts in the state penitentiaries to volunteer to submit themselves to the bites of presumably infected mosquitoes. All three species of mosquitoes were used, and various periods of the disease were used for the initial feedings and various intervals for the attempted human inoculations.

Here again all tests were negative.

In spite of entire failure under a wide variety of experimental conditions, we cannot say that the possibility of transmission of encephalitis by mosquitoes in nature is finally disproved. It would be extremely difficult, however, to account for the somewhat uniform diffusion of the disease over a wide metropolitan area on the basis of such transmission being the major factor in the spread of the disease.

In the 1878 yellow fever epidemic in St. Louis, there were 151 cases with 71 deaths, of which 31 (23 fatal) were of indigenous origin, and in general these cases were in groups closely connected geographically, without any diffusion over the city.

In view of the negative results of the insect experiments, the diffuse fashion in which poliomyelitis, except in the most intense epidemics, spreads through a community, without apparent contagion between cases, and the radial spread of this epidemic of encephalitis by communities, but not by individual cases, it appears likely that human contagion, chiefly by unrecognized carriers, is the method of infection here, but that susceptibility, in which age is an important factor, determines who will contract the disease in an infected community.

#### SUMMARY

1 The type of disease in the St. Louis outbreak was unlike that in the sporadic cases of the Economic disease but very much like type B of the Japanese outbreak in 1924, and almost exactly like the Paris, Ill., outbreak of 1933.

2 The cases were fairly accurately and completely reported.

3 The case rate for the entire area was 100 per hundred thousand—69 per hundred thousand for the city and 212 per hundred thousand for the county.

4 There was no predilection by sex or color.

5 There was a striking increase in both incidence and fatality rates with age.

6 The fatality rate was higher in the city than in the county.

7 The incubation period in different cases showed a variation between nine and fourteen days, with possibly wider limits.

8 There was a notable rarity of multiple cases in the same family and of obvious contagion between cases.

9 Between communities the spread was obviously by human contagion, but as regards individuals, individual

susceptibility, in which age played a part, appears to be more important than contagion.

10 The disease appears to be limited seasonally in its typical form.

11 Water supply and milk supply were eliminated as possible mediums of transmission.

12 Entomologic experiments with the mosquito as a possible vector were negative.

#### ETIOLOGY OF THE 1933 EPIDEMIC OF ENCEPHALITIS

RALPH S. MUCKENFUSS, MD

ST. LOUIS

CHARLES ARMSTRONG, MD

WASHINGTON, D. C.

AND

L. T. WEBSTER, MD

NEW YORK

The epidemic of encephalitis occurring in St. Louis and Kansas City during the summer of 1933 differed in a number of clinical and epidemiologic characteristics from the majority of previously reported epidemics. Since it is probable that these differences may be the result of different causative agents, no attempt will be made to review the voluminous and conflicting literature on the etiology of encephalitis, and this paper will be limited strictly to studies on the disease occurring in epidemic form in the recent outbreak.

Investigations into the etiology of the 1933 outbreak of encephalitis may be said to have begun before the nature of the disease was recognized or the onset of an epidemic was suspected. When the first few cases were admitted to the St. Louis County Hospital, the nature of the febrile illness was not immediately appreciated, and many cultures of blood and spinal fluid were made, as well as many examinations of blood films for malaria plasmodia. These were all negative, and it was only after the first autopsy that the nature of the disease was definitely established. As the outbreak continued, similar studies were made on patients in hospitals with continued negative results.

This much negative information was available, therefore, when the investigation was centralized by the Metropolitan Health Council in the laboratories of the Departments of Medicine and Pathology of Washington University School of Medicine. At this time the investigation was planned on a more extensive scale, and cultures of brain tissue were also made on autopsies, and in addition a variety of animals were inoculated. Brain tissue was removed aseptically by removing the skull plate without touching the dura, wiping off the dura with alcohol, opening it with sterile instruments, and removing bits of brain with a second set of sterile instruments. For culture, this material was transported to the laboratory in petri dishes and emulsified in a mortar under a hood. It was obviously impossible, with this amount of manipulation, to avoid occasional contamination, but in spite of this difficulty no growth occurred in about half of the material studied, and bacteria, when present, were few in number and of such variety that no one organism could be suspected of having etiologic significance. Furthermore, no bac-

From the Washington University School of Medicine, the U. S. Public Health Service and the Rockefeller Institute for Medical Research. Read before the Section on Preventive and Industrial Medicine and Public Health at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 15, 1934.

# ETIOLOGY OF ENCEPHALITIS—MUCKENFUSS ET AL

Jour. A. M. A.  
SEPT 8 1934

teria were demonstrated in stained sections of tissue. It seems obvious, from the outcome of this work, that the presence of ordinary bacteria in the blood, brain or spinal fluid can be excluded from any etiologic rôle in this disease.

A number of animals were inoculated by various routes, but intracranial inoculation of brain tissue was practiced most frequently, the emulsions prepared as for culture and diluted to about 10 or 15 per cent being commonly used. Since most of these inoculations gave negative results, they will not be described.

The negative results in rabbits, while not on a very large scale, comprised the use of over thirty animals by various routes of inoculation, and seem significant in excluding herpes virus from an etiologic role, since from a number of these samples of tissue, another virus that appears to be the etiologic agent of the disease was isolated.

Glycerinated brain tissue from fatal cases was made available, so far as possible, to laboratories outside St. Louis that were interested in studying the disease.

The virus that appears to be the etiologic agent was isolated almost simultaneously by Muckenfuss, Armstrong and McCordock,<sup>1</sup> using rhesus monkeys, and by Webster and Fite,<sup>2</sup> using a strain of mice bred at the Rockefeller Institute, and peculiarly susceptible to the action of neurotropic viruses. Strains of virus isolated in these two laboratories were exchanged and found to be similar in their characteristics.

The disease in the two known susceptible animals will be briefly described.

**Mice**—After the disease has been established in mice, passage in this animal is readily accomplished. In addition to the susceptible strain of Webster, Swiss mice and the stock strains of white mice available in the St. Louis area have been found to be uniformly susceptible.

Following intracerebral inoculation, the incubation period ordinarily varies between four and eight days and is most commonly five days. The animals then have ruffled fur, convulsions are common, and in a

Fig. 1—Perivascular accumulation of cells in brain of monkey

short time they become prostrate and respiration is barely perceptible. Death may occur rapidly, or the animals may remain in this state for several hours, and it is exceptional for an animal to recover after developing definite signs of illness.

Histologically there are accumulations of round cells around the blood vessels of the brain, and there is destruction of nerve cells, most marked in the hippocampus and cornu ammonis.

These changes are also observed in parts of the spinal cord.

**Monkeys**—These animals are less susceptible than white mice, and maintaining the virus in them is difficult. Following the intracranial inoculation of brain emulsions from fatal human cases of encephalitis (these inoculations were usually repeated on the fifth

Fig. 2—Perivascular accumulation of cells in brain of mouse

day), the incubation period was ordinarily between eight and fourteen days. At this time the temperature gradually rose, and at the same time the monkeys became weak, and tremors appeared. The tremors were particularly noticeable when the animals climbed the sides of the cage, and some incoordination was usually evident. The majority of the animals were killed for passage while symptoms were present, so it is impossible to state the usual outcome of the disease in monkeys. Since some monkeys were permitted to recover, it is possible to say that the disease is not necessarily fatal.

At autopsy, the brains were usually markedly congested, and histologic study revealed changes consistent with those observed in the human disease, namely, perivascular cuffing, nerve cell degeneration, and focal collections of cells. These changes were present in the brain and upper portions of the cord.

## CHARACTERISTICS OF THE VIRUS

Since mice are much more susceptible than monkeys, and since they are much more easily handled, the studies on the characteristics of the virus have been made with the use of mice. The virus is ordinarily active on intracranial inoculation in mice in a dilution of 1:1,000,000 of the mouse brain. Following intranasal instillation a somewhat larger dose is necessary for the disease to develop regularly. These two methods of inoculation are the only ones that have been found satisfactory for the production of the disease in these animals. The different strains of virus that have been isolated have been found to be similar in all essential respects so far as comparative studies have been made.

The virus has been reported by Webster and Fite<sup>2</sup> to be readily filtrable. Bauer, Fite and Webster<sup>3</sup> have according to the virus through graded collodion membranes the diameter of the virus particles to lie somewhere between 22 and 33 millimicrons.

The virus is neutralized by the serum of individuals convalescent from encephalitis in the 1933 outbreak and is not neutralized by the serum of normal individuals from uninfected areas.<sup>2</sup>

<sup>1</sup> Muckenfuss R S, Armstrong Charles and McCordock II A  
Pub Health Rep 48 1341 (Nov 3) 1933  
<sup>2</sup> Webster L T and Fite G L Science 78 463 (Nov 17) 1933  
<sup>3</sup> Bauer J H, Fite G L and Webster L T Proc Soc Exper Biol & Med 31 696 (March) 1934

This test is carried out by incubating serial dilutions of the virus with undiluted serum and inoculating the serum-virus mixtures intracranially into mice. Evidence of protection is then detected by comparing the number of mice dying in the lots inoculated with virus incubated with normal serum with those inoculated with virus incubated with immune serum.

The virus is also neutralized by the serum of recovered monkeys or mice.

Webster and Fite<sup>4</sup> have also reported that mice which have been inoculated subcutaneously or intraperitoneally do not develop encephalitis but become immune as tested by intranasal or intracranial inoculation.

Comparison with other viruses has been reported by Webster and Fite<sup>2</sup> and by Cox and Fite<sup>5</sup>. They have reported absence of cross immunization with the viruses of herpes, vesicular stomatitis and equine encephalomyelitis.

Furthermore, serum collected from individuals recovered from epidemic (lethargic) encephalitis from one to ten years after the acute attack, poliomyelitis, Japanese encephalitis, and Australian-X disease did not neutralize this virus in the hands of Webster and Fite<sup>6</sup>.

#### SUMMARY

A number of strains of a virus that seems to be the etiologic agent of the 1933 epidemic of encephalitis were isolated in two different laboratories. This virus acts on monkeys and white mice and is distinct from other previously known viruses. The number of strains of similar characteristics isolated, and the neutralization of the virus by serum of individuals convalescent from encephalitis in this epidemic, but not by the serum of individuals recovered from other diseases, justify the conclusion that it is the etiologic agent of the recent epidemic.

### THE SYMPTOMS AND DIAGNOSIS OF ENCEPHALITIS

(1933 ST LOUIS EPIDEMIC)

THEODORE C. HEMPELMANN, M.D.  
ST. LOUIS

The type of encephalitis that was epidemic in St. Louis during the summer of 1933 differed materially from the popular conception of epidemic, or lethargic, encephalitis as heretofore observed in this country. Not only was there an unprecedented number of cases occurring within a short period of time and in a restricted geographic area, but the course and symptomatology of the disease were unlike those commonly observed in the older variety of encephalitis. In brief, the St. Louis cases were characterized by a rather sudden onset, with headache, high fever, stiff neck, mental confusion, tremors and other neurologic symptoms, but only occasional transient ocular manifestations. Following a stormy course, in most instances rapid improvement occurred, leading to apparently complete recovery.

within two or three weeks and leaving no residual effects. The present report is based on a study of the records of 786 hospitalized patients, and personal observation of approximately 400 such cases.

As the proportions of the epidemic grew, it soon became evident that there were apparently two distinct phases to the infection. The first consisted of symptoms of a general or systemic nature, and the second was characterized by evidences of invasion of the central nervous system. Among the systemic manifestations may be mentioned such complaints as extreme lassitude, malaise, chills or chilly sensations, grippe pains in the back or limbs, nausea or vomiting, and abdominal pains. Somewhat less frequently there were also photophobia, catarrhal conjunctivitis, sore throat and rarely other signs of a mild infection of the upper respiratory tract. As involvement of the nervous system became apparent there was usually fever, severe headache, stiff neck, mental confusion and tremors, with a host of irregular neurologic signs and symptoms depending on the localization of the pathologic lesions. Moreover, since the disease affected by preference the older adults, the symptoms were often modified, or partially masked by preexisting pathologic conditions in these individuals such as senility, arteriosclerosis, chronic heart or kidney disease, or hypertension. Complications of this nature proved important factors in the prognosis, since the death rate was noticeably lower in children and in the younger, healthy adults.

Three distinct types of the disease were observed. In the purely encephalitic variety the symptoms referable to the central nervous system were evident from the very outset, often accompanied by certain of the systemic manifestations as well. In the second group the signs of a general infection without neurologic localization were present from one to four days or even longer before the encephalitic symptoms developed, suggesting a definite period of invasion of the disease. The third type was made up of the very mild and abortive cases, in which the symptoms were so indefinite that only the presence of an epidemic and the absence of any other explanation for the fever justified the lumbar puncture that was one of the chief diagnostic aids.

In the purely encephalitic or meningeal type of the disease, which was the commonest form observed, it was apparent at once that the infection involved the central nervous system. The onset was abrupt, with high fever, severe headache, neck rigidity, nausea and occasional vomiting, and usually somnolence, mental confusion, tremors, and difficulty in speaking. As a rule, the height of the disease was reached within the first twenty-four to forty-eight hours of the illness, but less frequently the onset was somewhat more gradual. During the same period, certain of the systemic manifestations were complained of as well and in a few patients, especially in children, convulsions occurred.

On physical examination, the commonest objective finding was rigidity of the neck or spine, and perhaps next in frequency was an absence of the abdominal reflexes, the latter vanishing early in the disease and returning with convalescence. In the majority of instances the Kernig sign was positive at some time during the course of the illness, but not always in the earliest phases of the disease nor in proportion to the amount of head retraction present. The tendon reflexes, such as the achilles and knee jerks, were inconstant, being oftener exaggerated than diminished. The

Read before the Section on Preventive and Industrial Medicine and Public Health at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 15, 1934.

plantar reflexes (Babinski, Gordon and Oppenheim) were extremely irregular and varied at different examinations in the same patient, but as a matter of fact almost all combination of pathologic reflexes were occasionally observed. The pupils, however, were usually small and equal, and they reacted well to

accommodation although there was an occasional sluggish response to light.

In conjunction with the development of the meningeal symptoms, many patients showed definite evidences of a rapid impairment of the mental faculties. Some were completely disoriented as to time and place, others remembered their own names and ages but could

Chart 1—Temperature of patient A M showing a typical curve

not recall where they lived, many during convalescence had no recollection of lumbar punctures, the early part of their illness or how they had come to the hospital. Moreover, the majority of patients showed a tendency to drowsiness or mental apathy, but rarely was coma so deep that the patient could not be aroused at least momentarily. In some instances, however, instead of lethargy there was excitement or mild delirium, and insomnia. At the height of the disease speech was often markedly affected, the impairment ranging from complete aphasia in a few to thick or slurred speech in others. Of equal significance was the appearance of moderately coarse or fine tremors, involving chiefly the hands, tongue and lips and persisting until well into the second or even the third week.

It is interesting to note that the striking ocular manifestations commonly observed in the ordinary epidemic, or lethargic, encephalitis were very rare. The most frequent complaint of this nature (present in about 14 per cent of the cases) was mild blurring of vision during the first day or two of the illness. Occasional instances of transient double vision, mild strabismus and nystagmus were observed, but ptosis was noticed only two or three times in this tabulation of 786 cases. Ophthalmoscopic examinations revealed no striking abnormality in the fundus.

Among the other symptoms noted were mild, transient vertigo in about one fourth of the cases, and more rarely definite ataxia. Slight degrees of exophthalmos were also observed a number of times, and in one patient this was most extreme. Deafness and ringing in the ears were infrequent complaints, disappearing within a few days. Hyperesthesias were common during the early phases and a few patients developed facial paralysis or a spastic paralysis of one or more extremities, these more serious manifestations as a rule disappearing by the end of the third or fourth week. Retention of urine or incontinence of urine and feces were common and at times suggested a possible spinal cord lesion. Vomiting was rarely ever forcible or persistent.

In the typical case of encephalitis, the fever was highest in the first two or three days of the infection and then in most instances fell by rapid lysis, so that the normal was reached within a week or ten days of the onset. Occasionally, however, the fever persisted for a much longer period, even up to a month or six weeks, with an irregular pattern. Improvement in the general condition was noted as the fever subsided. The pulse was ordinarily proportional to the temperature, but it was not at all unusual to find a marked bradycardia and less commonly a tachycardia present.

Examination of the blood as a rule revealed a moderate degree of leukocytosis, usually between 12,000 and 20,000, but a number of exceptions to this were observed with normal counts and occasionally even pronounced leukopenia. The Schilling hemogram was also variable, the most frequent finding being a slight shift to the left. There was no apparent relation between the severity of the infection and the leukocyte count.

In all cases of suspected encephalitis the spinal fluid yielded valuable information. In encephalitis the fluid was clear, under slightly or moderately increased pressure, and showed an increase of cells, most of which were of the mononuclear variety. The average cell count was perhaps between 50 and 250 cells, but occasional counts of 500 or 600 were observed, and in one of our cases up to 1,100. In a few instances early in the disease the first cell count was normal and subsequent punctures showed the typical increase. Rarely, the first counts showed one-third or even one-half the cells to be polymorphonuclears, but later punctures usually exhibited the typical mononuclear preponderance. The spinal fluid sugar was normal or slightly elevated, and the globulin only moderately increased.

With regard to the type of encephalitis in which there was a definite stage of invasion, the chief interest lies in a study of these prodromal manifestations, since once the neurologic symptoms developed the clinical course was indistinguishable from that which has just been described. Such premonitory symptoms were almost entirely of a systemic nature—chills or rigors, neuromuscular pains, headache, nausea, photophobia, sore throat. The temperature was often quite high at the outset, perhaps 103 or 104 F, but within the next few days there was usually a marked amelioration of the symptoms and the temperature tended toward normal, so that the patient seemed to be definitely convalescing. This stage lasted as a rule from one to four days, or occasionally even a week or more when suddenly the temperature rose rapidly to 104 or 105 F, the headache became much more intense, and the typical picture of encephalitis developed, with neck rigidity, tremors, mental confusion, and so on. Cases of this nature were rather frequent, but no particular influence on prognosis was noted in patients exhibiting this variation from the usual picture.

Finally mild or abortive cases occurred, the chief symptoms being fever, moderate headache and perhaps

Chart 2—Temperature of patient P R note bradycardia

mild systemic manifestations Occasionally, careful examination might reveal a suspicion of neck rigidity or slight tremors, but as a rule mental symptoms and abnormal neurologic signs were entirely absent In the presence of an epidemic of encephalitis, with no explanation being found for the fever, diagnostic lumbar puncture was regarded as warranted, and the typical increase in mononuclear cells then revealed in the spinal

A headache myalgia B apparent recovery, C mental confusion  
D coma E recovery

fluid, thus substantiating the diagnosis of encephalitis The course in such cases was usually brief, rarely lasting as long as a week

DIFFERENTIAL DIAGNOSIS

During the period of invasion, before neurologic signs had developed, the illness was often diagnosed influenza, until the subsequent course and lumbar puncture corrected the error Cases presenting chills, fever and no leukocytosis suggested the possibility of malaria, which was ultimately ruled out by the absence of the characteristic splenic enlargement, and of plasmodia in the blood smear, and the further development of the symptoms in encephalitis Typhoid was simulated very closely at times, especially when the patient had a leukopenia and bradycardia In typhoid, however, the onset is usually more gradual, the spleen is enlarged and soft, rose spots occur, and the blood culture and Widal test are valuable diagnostic aids Moreover, there is an absence of stiff neck, the Kernig sign, and spinal fluid changes in typhoid Delirium tremens may be much harder to rule out in patients with excitement and delirium Hallucinations are much less frequent and somnolence commoner in encephalitis, and the fever in association with the neurologic signs in the latter usually prompts lumbar puncture, which reveals the typical increase in mononuclear cells The two diseases may, however, be associated and produce a very puzzling picture Encephalitis and tuberculous meningitis may at times be indistinguishable in the early stages In tuberculous meningitis, however, the onset is ordinarily slower, the breathing often irregular, the course progressively downward to a fatal termination, and the tuberculin tests and roentgenograms of the chest may be suggestive Moreover, the spinal fluid in tuberculous meningitis shows pellicle formation, marked increase in globulin, diminished or absent sugar content, and tubercle bacilli Acute anterior poliomyelitis may exhibit symptoms and spinal fluid changes similar to encephalitis, but in poliomyelitis the sensorium is usually clear, speech is unaffected, and blurred vision, vertigo and pathologic plantar reflexes are rare, whereas they are relatively frequent in encephalitis The characteristic flaccid paralysis of various muscle groups that occurs in poliomyelitis is also quite different from the spastic extremities occasionally observed in encephalitis

Finally, differentiation from other forms of encephalitis may present difficulties In the so-called lethargic type there is no fever, ordinarily a more gradual onset, ophthalmoplegias, parkinsonism, and a chronic course, new symptoms appearing months after the onset, and often leaving residual manifestations But in the acute disseminated encephalomyelitis or so-called postinfectious encephalitis associated with measles, mumps, vaccinia, varicella, and the like, the symptoms may be so similar as to make differentiation impossible except by the history or, in fatal cases, by autopsy It seems probable from the preliminary studies on the blood of recovered patients in St Louis that the presence of neutralizing substances for the encephalitis virus may be utilized for differential diagnosis in such cases, at least after recovery has taken place

[EDITORIAL NOTE.—The four preceding papers, together with the four papers by Drs McCordock, Collier and Gray, Dr Eschenbrenner, Drs Bredeck and Zentay and Dr Jones, to appear next week, constitute a symposium on epidemic encephalitis, with particular reference to the St Louis epidemic of 1933 The discussion will follow the papers to be published in the next issue ]

BREAST AND ARTIFICIAL FEEDING

INFLUENCE ON MORBIDITY AND MORTALITY OF TWENTY THOUSAND INFANTS

CLIFFORD G GRULEE, MD  
Professor of Pediatrics Rush Medical College

HEYWORTH N SANFORD, MD  
Medical Director Infant Welfare Society

CHICAGO

AND

PAUL H HERRON, MD  
SPOKANE, WASH

There is no question that the artificial feeding of infants has taken remarkable strides in the past few years It has had such success that in the minds of many physicians and perhaps a large proportion of the public there has grown up the idea that artificial formulas can safely replace breast milk without any detrimental results to the child So far as we know, this has been based on empirical observations and has not been supported by sufficient evidence to be regarded as in any way proof Although in the past few years many accessory foodstuffs have unquestionably been discovered, notably vitamins, which are necessary for life, and it has been discovered also that in many instances the inorganic materials were of far greater importance than had been suspected, one cannot be at all certain that all the elements which go to make up a perfect food have been discovered More than likely many are not known Nor can one be sure, from present knowledge, of the quantity of each of the known elements necessary for an ideal food for an individual

Some may state that breast milk is not an ideal food, and this will have to be admitted to be the case in a few instances, but these cases may be regarded as pathologic rather than physiologic One has no right to assume, however, that one food is better than another simply because it is nature's own food, because in the individual instance there may be a reason why this pabulum is not ideal

Read before the Section on Pediatrics at the Eighty-Fifth Annual Session of the American Medical Association Cleveland June 13 1934

# INFANT FEEDING—GRULEE ET AL

JOUR A M A  
SEPT 8 1931

There are probably many standards by which one may judge the effect on the organism of the food offered it. It may certainly be said that weight alone is by no means the only criterion by which a food's value may be judged. Other physical qualities such as blood, tissue turgor or bone development, may be regarded as of importance. The child's resistance to infection may also be looked on as one of the chief

child's physical condition, the nurse, of course, is witness to its care.

As to the feeding of these children, the following were in general the methods used. Very rarely was there much deviation. In the first place, every attempt was made to keep the child on the breast for the first ten months. When this was not possible, complete mentary feeding was resorted to. The formula here was very much the same as that used for artificial feeding. The artificial feeding that was recommended in all instances was cow's milk (boiled five minutes) added to make a fluid content of from 2½ to 3 ounces the pound weight, and one-tenth ounce of cane sugar to the pound weight was then added. The latter was restricted to not more than six teaspoonfuls in twenty-four hours. Accessory foods were added as follows: Orange juice, beginning with a half teaspoonful in twenty-four hours at 4 weeks increasing to eight teaspoonfuls at 5 months. Cod liver oil, beginning with ten drops in twenty-four hours at 6 weeks, increasing to three teaspoonfuls at 5 months. Cereal was added at 5 months, vegetable at 6 months and the second cereal at 8.

There were 20,061 cases studied for nine months in this group. There were 9,749, or 48.5 per cent, infants entirely breast fed, with accessory feedings added. There were 8,605, or 43 per cent, that were partially breast fed with accessory feedings added and 1,707, or 8.5 per cent that were artificially fed (chart 2).

Chart 1—Nationality

Chart 2—Total number of cases 20,061 classified according to type of feeding

means by which one may judge of the effectiveness of the food offered. Many years ago Czerny and Keller emphasized this point, and in experiments with vitamins of recent date this point has again been brought out. It seemed to us, therefore, that it would be of value to survey a large number of infants as to the incidence of infection and other disturbances allied to it with respect to whether they were fed with breast milk or artificially.

## MATERIAL

The material contained in this series of cases consists of records taken from 20,061 babies who were under the care of the Infant Welfare Society of Chicago for as long as nine months during the years 1924-1929 inclusive. These represent all such babies that were under the care of the welfare society for that length of time. The Infant Welfare Society of Chicago has been in existence for nearly twenty-five years. It has stations in the poorest sections of the city and shares with the city health department the care of indigent infants and children of the city so far as infant feeding and care are concerned. The nationality of the group studied is shown in chart 1.

The medical supervision of these children consisted in a visit to the clinic station and an examination and feeding instruction by the station doctor at least once a month. Infants suffering from any disorder or disease are seen as frequently as the station doctor thinks advisable. The nurse visits the home within a week after the child is first brought to the station and gives the mother advice regarding the nursing of her child or the preparation of the formula. Thereafter the nurse makes home calls as often as is deemed necessary. During the period under discussion this was at least once a month. Whenever the child is sick the parents notify the station and the nurse visits the child. If the situation warrants it the child is referred for medical attention. Thus a very close check is kept on the

Chart 3—Total infections

Chart 4—Respiratory infections

Chart 5—Gastrointestinal infections

## MORBIDITY

In the study of morbidity, any note on the chart that indicated any feeding disturbance, cold or respiratory infection or other infection, is classified as an infection. These were divided into three main groups: respiratory, gastro-intestinal and unclassified infections. There were 3,646 infants in the breast fed group with infections, or 37.4 per cent. There were 4,629 infants with infections in the partially breast fed group or

53.8 per cent and 1,085 infants with infections in the artificially fed group, or 63.6 per cent (chart 3)

There were 2,729, or 28 per cent, of the breast fed infants that suffered from a respiratory infection of some type. In the partially breast fed group there were 2,925 infants, or 34 per cent, that had respiratory infections, and 665 infants, or 39 per cent, of the artificially fed (chart 4)

Chart 6—Unclassified infections

Chart 7—Total deaths (218 or 11 per cent)

In the gastro-intestinal disorders there were 505 infants in the breast fed group, or 5.2 per cent. In the partially breast fed 1,101 infants were affected, or 12.8 per cent, and in the artificially fed 273 infants, or 16 per cent (chart 5)

In the unclassified infections there were 322 infants in the breast fed group, or 3.3 per cent, 516 infants in the partially breast fed, or 6 per cent, and 139 infants in the artificially fed, or 8.2 per cent (chart 6)

#### MORTALITY

There were 218 deaths during the five year period, giving a total mortality of 1.1 per cent, or eleven deaths per thousand. Of the infants that died, there were 15, or 6.7 per cent, in the breast fed group, 59, or 27.2 per cent, in the partially breast fed group, and 144, or 66.1 per cent, among the artificially fed (chart 7)

There were 130 of the infants, or 60 per cent, that died from respiratory infections. Of this number four, or 3.3 per cent, were in the breast fed group, forty-four, or 34.6 per cent, in the partially breast fed group, and eighty-two, or 62.1 per cent, among the artificially fed (chart 8)

Twenty-two of the infants, or 10 per cent, died from gastro-intestinal disturbances. Of these two, or 9 per cent, were in the breast fed group, six, or 27.3 per cent, in the partially breast fed group, and fourteen, or 63.7 per cent, among the artificially fed (chart 9)

Sixty-five of the infants, or 30 per cent, died from unclassified infections. Of these seven, or 12 per cent, were in the breast fed group, twenty-five, or 36.8 per cent, were in the partially breast fed group, and thirty-three, or 51.2 per cent, were in the artificially fed group (chart 10)

#### RESULTS

These figures do not need any particular explanation or discussion. It will be observed that in every instance, from the point of view of feeding, breast feeding gives a much greater immunity to infections than artificial feeding. It is shown that even a partial breast feeding gives considerable immunity

Roughly it shows that, baby for baby, the breast fed infant will have a 50 per cent better immunity than one that is artificially fed

Among the gastro-intestinal disturbances there were twice as many disturbances in the partially breast fed as in the totally breast fed, and three times as many in the artificially fed as in the totally breast fed. The same proportion is true in the unclassified infections, while in the respiratory infections the discrepancy was not so marked. Still, there is a distinct difference between the breast and the artificially fed infants. These differences, however, in the three classifications are not nearly of the same significance as the difference shown in the mortality statistics. The general mortality was ten times greater in the artificially fed than in the breast fed. The partially breast fed had four times the mortality of the totally breast fed and only one-third that of the artificially fed.

In the respiratory disturbances it is shown that, while the breast fed baby has a morbidity of 10 per cent less than the one artificially fed, the mortality is only one-twentieth as high, while even the partially breast fed infant has ten times the breast fed mortality and only half that of the artificially fed. In the gastro-intestinal disturbances the breast fed mortality was 9 per cent, while the artificially fed baby had seven times the mortality and the partially breast fed three times. In the unclassified infections the mortality of the partially breast fed was three times that of the breast fed and the artificially fed four times.

It must be remembered that the years 1924 to 1929 were the years of plenty. Undernutrition does not enter into the picture. Here are 20,000 infants that

Chart 8—Deaths from respiratory infections 60 per cent

Chart 9—Deaths from gastro-intestinal infections 10 per cent

Chart 10—Deaths from unclassified infections 30 per cent

represent a true cross section of the national urban life. It cannot be said that these are uncared for slum babies, because the general mortality was only 11 per thousand, or less than one fourth of the infant mortality of the same region, yet in 85 per cent of these 20,000 babies was 66 per cent of the total mortality. If the artificially fed babies are taken from the total, the mortality is only 4 per thousand, and if only the breast fed are considered it is only 1.6 per thousand.

# INFANT FEEDING—GRULEE ET AL

Jour A  
SEPT 6

Obviously, therefore, if one hopes to decrease further the infant mortality of this country it must be done by encouraging breast feeding

## CONCLUSION

In a study covering 20,061 infants from birth to 9 months during the years 1924-1929 inclusive, 48.5 per cent were totally breast fed, 43.0 per cent were partially breast fed, and 8.5 per cent were artificially fed. The total morbidity of the breast fed group was 37.4 per cent, of the partially breast fed group 53.8 per cent, and of the artificially fed group 63.6 per cent. The average mortality of these infants per year was 11 per cent. Of this mortality 67 per cent were in the breast fed group, 27.2 per cent in the partially breast fed group, and 66.1 per cent among the artificially fed.

310 South Michigan Avenue—952 North Michigan Avenue—  
Spokane Medical and Surgical Clinic

## ABSTRACT OF DISCUSSION

DR FRANK C NEFF Kansas City Mo From the results of this survey it is evident that breast-fed babies have a better chance against infection. Therefore it is advisable to make every effort to maintain breast feeding from the first days of life. Dr Dwyer and I presented a joint paper two years ago on the subject of feeding in the obstetric nursery. For a period of two years at the University of Kansas Hospital we had followed the usual custom of trying to make the baby regain its birth weight by the time it was 10 days old. To do this the child was bottle fed in addition to breast feeding. That is the custom in most nurseries of private hospitals. It is difficult to insist on breast feeding because nurses and physicians are eager to have the infant show the greatest possible gain. In the last two years we have undertaken an experiment, while measuring all the breast milk that every infant gets during the stay in the nursery, to see how many infants can be sent home on the breast alone. In our hospital the control of the nursery feeding is centralized. A much greater percentage are being breast fed the next best thing to do is to keep infants on mixed feeding and to see that complementary food does not displace the breast feedings. We have found that it is possible for the baby to have mixed feeding without any great diminution in the amount taken from the mother's breasts, if it is assumed that the mother will be given every chance to maintain her supply.

DR PAUL H HERRON, Spokane Wash In compiling these statistics it took three of us between two and three years' time. This paper is not based on a selected group of cases but represents every case seen by the infant welfare doctor for a period of nine months. No case is included in the report that was not seen for this length of time. The nationalities shown were varied. Some of the infant welfare stations as sent Italians almost entirely, others Russians and so on. I wish to reemphasize the fact that this is probably the reason we found such a high incidence in our breast-fed infants. In private practice we do not get 48 per cent of breast-fed infants. All breast-fed infants are fed five times a day every four hours after they reach about 8 pounds (3.6 Kg). They are fed this way until they attain the age of 10 months. All artificially fed and partially breast-fed infants receive as complete feedings milk water and sugar. Very few of the earlier infants received milk additions other than cow's milk, but these were almost negative. I hope that we can present the factual evidence that after all breast milk is the ideal food to be used in the feeding of infants.

DR JAY I DURAND Seattle There is no question that breast milk is as good a food or is the best food that has ever been devised, but I doubt whether the statistics presented represent the state of affairs that would be obtained if artificial feeding was properly carried on and if one had an intelligent mother and nurse to prepare the feedings. In the first place these are statistics of 1924 to 1929 and artificial feeding today

is a very much more successful procedure than the artificial feeding of ten years ago. In the second place, I have statistics from another source quite as valuable as the ones presented today. Twenty years ago I worked for six months in Finkelstein and Meyer in the orphanage in Berlin. Three years ago I went back and spent considerable time there. In the institution there are 600 infants admitted a year, most of them in all of the had cases, and thirty or more wetnurses who fed 100 babies were kept in the institution. Three years ago all the wetnurses were dismissed and all babies were fed artificially. Twenty years ago the mortality in the Waisenhaus was about 14 per cent, three years ago the mortality was 25 per cent, and during that time breast milk feeding had been discontinued. Breast milk is the safest food and the most fool proof mothers are from the slum districts, only 10 per cent American, the statistics will show a great advantage for feeding but with intelligent mothers and capable direction today is higher on artificial food than it is on breast. Dr Faber of San Francisco compared the mortality and morbidity for several years in a group of cases cared for in Stanford outpatient department. He tried to get 100 breast fed babies and 100 artificially fed but never could get quite 100 exclusively breast fed. Dr Faber followed these cases over a three year period and found that the bottle fed children had as little illness and grew quite as well as those fed by their mothers.

DR BERTHOOLD FLEISCHMANN, New York I want to agree with almost everything that Dr Durand has said. I too have been fortunate as he, in having been to the Finkelstein asylum. At the time I was there, some eight years ago, they also had a system of wetnurses, and it still was being continued in some cases but not in all as previously. I want to make one remark regarding the cases presented here. In private practice the morbidity is less than in dispensary practice, for the reason that the level of intelligence in the home is greater, and often the question of the size of the family is important, as to the amount of care the child gets.

DR CLIFFORD G GRULEE Chicago There are several ways in which one can look on such statistics. It seems to me that one must gage them largely from the question of the general good. It is much simpler both for a well-to-do patient and for an indigent patient to nurse the baby at the breast. The propaganda that has gone out in the last few years by no means wholly from the profession but largely over the radio, has tended to belittle the good that one gets from breast feeding. Dr Neff's point is that the determination of breast feeding is made largely in the first two weeks of life. If the child goes out of the hospital artificially fed it never gets breast milk again and the most that can be said is that it has lost a definite advantage in the fight for life because it is extremely hard to feed a baby properly in the first two weeks of life. Some of them go along beautifully a great many of them do not. Dr Durand's idea that these statistics cannot be carried into private practice is perfectly correct. There is nothing like the same morbidity or mortality in private practice that there was among these cases. The mortality among these infants was just about one fourth of the general mortality in the same region so that we did not have an excessive mortality. The difference in mortality from gastro-intestinal disturbances would probably have been more marked had employed wetnurses at the present time. The difference is a difference in mortality from infection. Mortality in the last few years especially of respiratory infections, has been far above anything that occurred from gastro-intestinal disturbance. Such statistics as he offers in regard to infants in an orphan asylum are not comparable to those which we have had here. A point has been reached in combating infant mortality which compels one to take a somewhat different standpoint. No inroads to amount to anything have been made on the infections that occur in children and cause so many deaths especially respiratory infection. That peak still holds and is not much reduced. It has not been possible to carry by direct assault and so indirect methods must be resorted to. This group is of importance because these children

dren were exposed to infections far more than the average group in better households. They were members of families of five or six children attending school and likely to bring back infections. To reduce infant mortality, that group must be protected. I do not know at the present time of a better method than by promoting breast feeding. In the last five or ten years quite a little has been learned about infant feeding, but I do not believe that there is any food for artificially feeding infants comparable to breast milk, and I have yet to be shown by statistics that that is true. I want to call attention to the fact that one cannot draw conclusions from 100 or 200 cases

## ALCOHOL AND AUTOMOBILE ACCIDENTS

HERMAN A. HEISE, M.D.  
MILWAUKEE

That the problem of controlling the drinking driver and pedestrian is far from being solved may be due, in part, to the fact that no accurate statistics are available regarding the relationship of alcohol to automobile accidents, as well as to the fact that the diagnosis of drunkenness is, to a great extent, still made through unreliable physical observations.

TABLE 1—Analysis of 119 Consecutive Automobile Accidents

	Number of Accidents	Injured	Killed
Alcohol	74	155	10
Alcohol less than 0.02 per cent	45	44	7

TABLE 2—Sex of Driver

	Male Drivers	Female Drivers
Alcohol	73	1
Alcohol less than 0.02 per cent	41	4

TABLE 3—Type of Accident

Type of Accident	Number of Accidents		Number Injured		Number Killed	
	Alcohol	Alcohol Less Than 0.02%	Alcohol	Alcohol Less Than 0.02%	Alcohol	Alcohol Less Than 0.02%
Ran off road or upset	31	15	60	24	7	1
Collision	21	9	64	14	1	1
Pedestrian struck	23	19	20	17	2	5
Miscellaneous	1		1			

In a previous paper<sup>1</sup> the chemical test for alcohol in body fluids has been shown to be specific and a practical method for confirming a diagnosis of drunkenness, thus aiding in the conviction of drunken drivers.

In the present paper a further study has been made of the subjective and objective symptoms due to a consumption of alcohol correlated with the chemical examinations, and an analysis of 119 automobile accidents involving injury or death to 216 persons has been made in an effort to obtain a closer estimate of the role that alcohol plays in these accidents.

In order to demonstrate the effect of small amounts of alcohol, subjects were each given 30 cc of whisky and both subjective and objective symptoms were

recorded. Controlled typewriting experiments were used as a measure of efficiency. All subjects in this group suffered a measurable loss of efficiency, generally gaining increased speed at the expense of accuracy, although the alcohol in the urine did not exceed 0.02 per cent. It should be borne in mind that 0.02 per cent alcohol in the urine or blood was the limiting value

Chart 1—Analysis of 119 automobile accidents. In the charts black represents alcohol; white, less than 0.02 per cent.

used in the "alcohol accidents" in the analysis given later.

A second series of experiments was performed under actual driving conditions, incidentally making use of the device to measure the time elapsing between a signal and the application of the brakes that has been described in a previous paper.<sup>2</sup> In these experiments a larger amount of whisky, namely, 150 cc, was given. With no exceptions these subjects were able to pass creditably the ordinary tests used to determine drunkenness and were able to perform adequately the routine actions

Chart 2—Type of accident

involved in driving. However, there was a definite variation from the normal in actions that had not become a habit, such as avoidance of obstacles placed in the road, backing the car, which was poorly and inaccurately accomplished, and the substitution of an unusual action for one that was normally used (such as using the hand brake rather than the foot pedal).

From the Columbia Hospital.  
Read before the Section on Miscellaneous Topics, Session on Forensic Medicine, at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 13, 1934.  
1. Heise, H. A. The Specificity of the Test for Alcohol in Body Fluids. *Am J Clin Path* 4: 182 (March) 1934.

2. Heise, H. A. and Halporn, Benjamin. *Medicolegal Aspects of Drunkenness*. Pennsylvania M J 36: 190 (Dec) 1932.

All subjects admitted disorientation and either depression or exhilaration. Reaction times were somewhat increased and all subjects displayed a lack of appreciation of changes in judgment and motor control. The alcohol percentage in these individuals did not exceed 0.10.

These experiments are cited to illustrate the lowered efficiency of the alcohol consumer and, incidentally,

Chart 1—Accidents according to the day of the week

offer added evidence that it is not primarily the obvious "drunk" who constitutes a major road menace but the man I have termed the "drinking driver" and with whom this series of cases is largely concerned.

Table 1 is an analysis of 119 consecutive automobile accidents in all of which the victims required hospital treatment. All but two were treated in the Uniontown Hospital. As Uniontown is a city of 20,000 population, situated on the National Highway in southwestern Pennsylvania, this survey comprises a fair distribution of urban, rural and tourist traffic accidents.

Not only were the "alcohol accidents" more numerous than those not involving alcohol, but they were responsible for injury or death to more than two people per accident, while the nonalcohol accidents involved slightly more than one person per accident.

Further investigation along this line may furnish the explanation for the fact that women drivers are involved in fewer accidents than would be expected from the known ratio of the number of women drivers to men drivers. A surprising fact, however, is that the five women drivers were involved in three fatal accidents. The most important observations expressed in tables 1 and 2 are shown graphically in chart 1.

The data in table 3 are shown graphically in chart 2.

In cases in which the car ran off the road or was upset, the average percentage of alcohol in the blood

Chart 4—Accidents according to the time of the day

or urine in the alcohol cases involving injury was 0.15 while the average alcohol percentage in the fatal cases was 0.24.

In cases of collision, the average percentage of alcohol was 0.21.

In accidents to pedestrians the alcohol average for drinking drivers was 0.14 per cent and for drinking pedestrians was 0.20 per cent.

There is a direct relationship between the severity of the accident and the amount of alcohol.

Three of the pedestrians in the age group from 16 to 60 years (table 4) were hit by unapprehended "hit and run" drivers.

In this series the drivers who struck children or old people were in most cases sober. The largest number of accidents in this group involves the drinking pedestrian.

Table 5 shows that in this series a driver with normal alcohol in the blood and urine usually had sober people in his car and that those who had a high percentage of alcohol had passengers who were about equally

"high." Possibly a sober man will not be a passenger when his host is intoxicated.

Chart 3 reveals that increased traffic alone is not the chief cause of week-end accidents. The unmistakable role of alcohol is demonstrated by the tremendous week-end peak in the "alcohol accidents," while the others increase but slightly. It will be noticed that while the ratio of "alcohol" to "nonalcohol" accidents on Sunday is almost three to one, the number of persons injured or killed is almost eight to one. On week days no such disproportion is noted.

That darkness is associated with a definite driving hazard is shown by the increase of "nonalcohol" accidents during the early evening hours. An additional

factor may be fatigue, the effects of which are very similar to alcoholic intoxication. The imbiber, however, reaches a much higher peak between 6 and 7 p. m., which is probably the result of the "cocktail hour," and another peak at midnight. In the daylight morning hours almost all accidents are of the nonalcoholic type.

Table 6 shows nine consecutive accidents involving "hit and run" drivers and all are remarkable for the high percentages of alcohol. It is possible that alcoholic intoxication adds an additional factor of fear of apprehension, or the alcohol may make capture easier, as in one case in which zigzag tracks in the snow made by the car wheels led from the scene of the accident.

#### SUMMARY AND CONCLUSIONS

1 Experiments indicate a measurable loss of efficiency and judgment, even when small amounts of alcohol are accumulated in the blood or urine.

2 Considering a person sober as long as he can still walk and talk is responsible for the small value of present day statistics regarding the relationship of alcohol to automobile accidents.

3 By analyzing consecutive accident cases involving injury and death, it is possible to throw light on the high incidence of week-end accidents and night accidents, and the surprising preponderance of accidents in which male drivers are concerned.

4 In this series the drinking pedestrian was concerned with many accidents, in most cases a child or old person was struck by a sober driver.

5 It is recommended that the chemical test for alcohol, which has been proved to be practical in confirming drunkenness and thus aiding in the conviction of drunken drivers, be adopted universally, at least to confirm the observations obtained by physical examination.

#### ABSTRACT OF DISCUSSION

DR ALEXANDER O GETTLER, New York. I was interested to hear Dr Heise say he gave alcohol to individuals, put them in automobiles and watched them drive very interesting experiments. In New York we are not permitted to conduct such experiments. I should like to ask Dr Heise how he obtains permission for experiments of this kind.

DR WILLIAM D McNALLY, Chicago. I should like to ask Dr Heise if he has any statistics on how many accidents occurred before prohibition, during prohibition and after prohibition. As an observer of drunkenness, I find that more drunkenness has existed since prohibition has been repealed. I wonder if we have more accidents.

PROF R N HARGER, Indianapolis. I should like to ask Dr Heise what he called an alcoholic person, whether he used any quantitative figures. I consider this a very important paper and I believe more data are needed on the correlation between the level of alcohol in the body and the degree of intoxication. I am interested that he has confirmed the work of Miles and others to the effect that low blood alcohol figures varying say from 0.5 to 1.5 parts per thousand which were previously felt not to be dangerous, may really be a menace to the public.

DR H A ROTHROCK JR, Bethlehem, Pa. I should like to ask Dr Heise if he has any data in relation to the hit and run driver and also as to the condition of the alcoholic state of the other passengers in the automobile.

DR CHARLES NORRIS, New York. In 1926 a compilation of statistics revealed that the alcoholic deaths of pedestrians who were run over (the cases were all taken from Manhattan) represented about half the number of automobile deaths in the greater city. Between 22 and 25 per cent of those who were run over and died were 3 or 4 plus, namely, they were intoxicated at the time of death.

DR W C WOODWARD, Chicago. I should like to call attention to the importance of maintaining the differentiation between the meanings of the term "intoxication" and the term "drunkenness." There is danger of falling into the confusion that has existed with respect to the meaning of the term "insanity." Drunkenness is distinctly a social and legal condition. Intoxication is not, it is a biologic or physiologic or pathologic condition. While chemical tests can prove that a man is intoxicated they cannot prove that a man is drunk. They are, as Dr Heise has pointed out, only valuable confirmatory evidence.

DR HERMAN A HEISE, Milwaukee. Regarding Dr Gettler's inquiry as to how consent is obtained to experiment on drunken drivers using city streets. The mayor set aside a certain part of the city of Unimtown and had it patrolled by police. We could drive back and forth to our hearts' content and shoot the guns in the city limits, the guns marking the length of time between the impulse and the application of the brakes. Regarding the number of accidents before and after repeal there seems to be a slight increase in the number of accidents after repeal over the number before. No definite amount of alcohol in body fluids has been officially designated above which a person is intoxicated and below which he is sober. For this survey I have arbitrarily chosen 0.02 per cent as the dividing line, since it clearly designated the drinking driver, and experimental evidence indicated psychologic inferiority. As to intoxication and drunkenness. I wouldn't use the term "drunkenness" in court. It simply causes trouble. Alcoholic intoxication means "under the influence of alcohol." If a certain amount of alcohol is found and that person has acted abnormally because of alcohol, I think one can state definitely that this person is "under the influence."

#### SOME NEWER CONCEPTIONS OF URINARY STONE FORMATION

J DELLINGER BARNEY, MD

AND

E ROSS MINTZ, MD

BOSTON

This communication concerns itself primarily with a discussion of hyperparathyroidism as a cause of urinary calculi. In the course of our remarks, certain other possible etiologic factors will be dealt with.

Next perhaps to malignant disease, urinary lithiasis presents one of the most difficult problems confronting the urologist. Until this question is answered he finds himself occupied in the more or less unproductive occupation of discovering and removing stones from the kidney, ureter or bladder. We do not hesitate to say that no hypothesis as to etiology yet presented can be defended from every line of attack, nor does it matter that certain experimental studies have resulted in stone formation. What may be true in the laboratory does not necessarily follow in the clinic. Even parathyroid disease, which is found to be the apparent etiologic factor in at least 10 per cent of cases, brings up questions that in the present state of knowledge cannot be answered.

It will be impossible for us to discuss and summarize the vast literature of urinary lithiasis. Until recently it was based only on clinical observation, theorization and empiricism. Only in the past ten or even five years has anything been done by investigators with the lamp of modern biochemistry and physiology to light their path. Even with the progress that has now been made it is obvious that the knowledge of neither the biochemist nor the physiologist is such that he can explore

From the Urological Department, Massachusetts General Hospital.  
Read before the American Association of Genito-Urinary Surgeons,  
Hot Springs, Va., May 15, 1934.

the even more complicated problems that have already arisen

In the light of the work of Keyser, Joly, Higgins, Hinman, McCarrison, Randall, Holmes, Coplan and others, to mention only a few, we have nothing new to add except our experience with hyperparathyroidism. We do feel, however, that long continued and intensive clinical observation, careful reading of the literature, and intimate contact with our colleague Albright, who has done epochal work, enable us to express views that will at least provoke further discussion.

Before going on to a consideration of the etiologic importance of the parathyroid gland, we wish briefly to touch on other possible factors in the production of stone. We believe with others that the colloids of the urine play an important role and that whatever "brings about imbalance in the solvent capacity of the protective colloids"<sup>1</sup> may result in crystalline deposits. Keyser seems to feel that, at least in the formation of the so-called primary stones without infection, "some error of metabolism" occurs. In addition to this there would appear to be some disturbance of the normal physiologic function of the kidney that induces the formation of stones in one organ rather than in both. If infection occurs in the presence of a stone in an acid urine, especially by a urea-splitting organism, changes may be expected in the character of the stone, one layer or the nucleus itself being that deposited in the presence of the acid sterile urine, and another being laid down by the infected alkaline urine. It seems to be a fact that the chemical character of the stone which occurs in or as a result of infection is very different from that in a clean and acid urine. Yet one must not forget that in various reported series of renal stones, some of them of the so-called secondary variety, investigators have found a persistently normal uninfected urine in from 10 to 20 per cent of cases.

When the various dietary and vitamin deficiencies are considered, so much contradictory evidence is found, both clinical and experimental, that in the present state of knowledge it is impossible to draw any accurate conclusions. That these deficiencies are of some, if not great, importance, no one can deny, nor can it be denied that their geographic distribution is of significance. A great deal of most intensive study must yet be brought to bear on these phases of the situation before it will be known how to interpret their meaning.

While infection plays its part, comparatively little is known about it. There is also much conflicting evidence as to whether it is a primary or secondary occurrence. It seems to be clear, however, that it may alter the composition of the stone in a variety of ways, but just what goes on still remains to be discovered. Under the same caption faulty drainage can be included, but rather quickly dismissed, as an item of importance. While it may induce or increase infection, every one knows that it may continue almost indefinitely without resulting in stone formation. Yet neither of these factors, especially infection, can be allowed to continue if the chance of calculus deposits is to be lessened.

It is obvious from all this that many factors are undoubtedly at work and that each must be evaluated. As Randall has wisely said, "The cause of stone must vary, for the effect is known to be a variant."

When the answer to all these questions has been discovered it will be known why stones form, why they vary in their composition, why they occur in one kidney

and not in the other, why after removal they may recur in some instances (variously estimated as from 5 to 20 per cent) and not in others. It may also explain why children are for the most part so free from stones.

Having dealt with the negative side of the question, we shall now take up the positive side and narrate some of our experiences with parathyroid disease in its relation to stone. Various communications, especially those of Albright, Aub and Bauer, have shown that disturbance of the parathyroid has a far-reaching clinical effect. In their most recent article<sup>2</sup> they have discussed at length the extraordinary variety of symptoms to which hyperparathyroidism may give rise.

As knowledge of and interest in this disease extends over only a comparatively brief period, the material we have used dates back only to 1933. During this time 104 patients with urinary calculi, having a complete blood examination for calcium and phosphorus, in some instances more than once, have been operated on and stones have been removed. This number does not include a similar number in whom the blood was not investigated. In twenty marked for rechecking, the results proved to be negative in seven. Four of the remaining thirteen cases not yet reexamined would appear to be definitely instances of parathyroid disease if the blood examinations are to be depended on.

Our interest lies, however, in a group of eighteen cases of hyperparathyroidism, so proved by operation, eleven, or 61.1 per cent, of which presented not only parathyroid tumor but also urinary calculi. These eleven cases are included in the 104 previously mentioned, giving a total percentage of 10.5. As already stated, there are other cases in this group which may prove to be positive, thus increasing this percentage very appreciably.

These eleven patients, all bearing stones, together with seven others, having not stones but cystic degeneration of the bones, have all been operated on by Drs. E. D. Churchill and Oliver Cope at the Massachusetts General Hospital, creating, we believe, a unique experience for all concerned. A report of some of this work has already been made.<sup>3</sup> In most cases of lithiasis the parathyroidectomy followed the lithotomy.

It is interesting to note that of the eighteen patients twelve, or 70 per cent, were females and that the youngest patient was 13 and the oldest 62, with an average age of 43. The calcium blood content varied from 11.5 to 16.8, with an average of 13.78, the phosphorus content averaged 2.55, ranging from 1.4 to 4.7. It may be remarked that a serum calcium above 11 mg per hundred cubic centimeters and a serum phosphorus below 3.5 mg should always arouse suspicion. Bone involvement, ranging all the way from large multiple cysts to simple decalcification, was found in twelve, or 70.5 per cent, of cases. In six cases, stones and bony changes were found together. The stones were bilateral in four, or 36 per cent, of the eleven cases, and the urine was negative in 35 per cent. There has been no operative mortality. One patient, however, died in the hospital about one month after his seventh operation, at which time the parathyroid tumor was discovered behind the sternum and removed by Dr. Churchill. The cause of death was uremia, the direct result of parathyroid disease. The urologic surgery in these cases was done by various members of the staff.

<sup>2</sup> Albright, Fuller, Aub, J. C. and Bauer, Walter. Hyperparathyroidism. J. A. M. A. 102: 1276 (April 21) 1934.  
<sup>3</sup> Churchill, E. D. and Cope, Oliver. Surg. Gynec. & Obst. 55: 255 (Feb.) 1934.

We have given the details of these cases, not because, so far as the urologist is concerned, they differed in any way from other cases of urinary lithiasis but because they were associated with parathyroid disease and because of this are highly interesting and important Papers by Albright and by Churchill and Cope which have already been published or are to appear later describe in detail the medical and surgical problems encountered

Our interest in this problem led us to a careful follow up of as many of our cases of urinary lithiasis as we could recall. These patients have all been operated on and stones have been removed. To date thirty-three have been examined by us, this examination including the calcium and phosphorus blood contents and roentgen studies. Of this number eleven, or 33 1/3 per cent, have the high blood calcium that is so consistent with parathyroid disease, and although in some of these the phosphorus content is rather high they must all be checked up and studied even more minutely. In only two cases, however, do there appear to be any bony changes. As yet no really complete follow up has been done in the proved hyperparathyroid cases. This will be done in due course and a report made

It will be noticed that we have said nothing about the chemistry of the stones removed in these cases of parathyroidism. As Albright, Aub and Bauer have pointed out, "If the stone is the result of hyperparathyroidism, it should contain a large amount of calcium and phosphorus," and in fact this is the case. We are not yet prepared to remark on the chemistry of these stones because no great amount of data is yet available, and also because it is to be reported at a later time by Albright and his co-workers. Experience has shown that the proper study of these calculi can be done only by a highly trained physical chemist. We believe that such an investigation may throw much valuable light on the etiology of calculi in general.

Not only our experience but that of many others has shown the close and frequent relationship of urinary calculi and parathyroid disease. A perusal of the literature, while by no means exhaustive, has been illuminating. Hunter<sup>4</sup> in 1930 collected thirty-two cases of osteitis fibrosa in which there was satisfactory proof of hyperparathyroidism. In ten of the thirty-two cases (31.2 per cent) renal calculi were found. In one instance renal calculi began to break up a few weeks after the removal of the parathyroid tumor and were passed into the bladder. Sixty-five cases of parathyroid disease have been reported by thirty-six other authors. Stones were present in fifteen, or 23.07 per cent, these being bilateral in ten, or 66 per cent. While many other cases of hyperparathyroidism have been reported by other investigators we have considered only those which were more or less associated with urinary lithiasis.

From all that has been said, it is obvious that we are dealing with a factor of the utmost importance in the etiology of stone. Whether the whole story has yet been told we doubt very much. The discovery is to be developed still further, and during this process it may shed light on other phases of the calculus problem. As yet it does not answer all the questions. If hyperparathyroidism is in the nature of an endocrine dysfunction, it must be generalized throughout the body and the urinary tract. Why, then, does it not result in stones in all cases or in bilateral stones uniformly?

The fact that it does not would indicate that there must be some still unknown factor at work in the kidney itself which prevents stone formation in some cases. By the same reasoning there must be a local renal factor that induces unilateral stone in certain individuals and bilateral stones in others.

Perhaps a still more intensive study of the colloids will supply the answer. Possibly dietary and vitamin deficiencies or errors will be found to play their part more than seems now to be the case. Also it may be possible that infection or even stasis will come to be regarded more seriously. That some disturbance of metabolism, plus a factor or factors existing at least temporarily in one or both kidneys, is at work seems a plausible working hypothesis. The realization that hyperparathyroidism will account for at least a part of the problem is important and encouraging. Further studies by the endocrinologist and the biochemist, as well as by the physiologist, will, we feel sure, eventually succeed in solving the question of urinary stone formation.

87 Marlboro Street

## INHALED SILICA AND ITS EFFECT ON NORMAL AND TUBERCULOUS LUNGS

LEROY U GARDNER, MD  
SARANAC LAKE, N. Y.

It is no longer reasonable to maintain that all kinds of dust are equally dangerous to the lungs. A very convincing array of clinical, statistical and experimental observations has demonstrated that dusts composed, in whole or in part, of silica are capable of exciting a characteristic, progressive, nodular fibrosis of the lungs and that at the same time these organs become abnormally susceptible to the tubercle bacillus. All the other types of dust that have thus far been investigated can apparently be inhaled almost with impunity for long periods of time.

It was originally claimed that only uncombined or "free" silica in the form of quartz was capable of producing this effect, but in recent years there has been a growing tendency to look with suspicion on some of the silicates (combinations of silica with bases). One of them, asbestos, a silicate of magnesium, is now a well recognized cause of pulmonary fibrosis, although the reaction is diffuse and not nodular in character. Jones,<sup>1</sup> an English geologist, claims that a silicate and not free silica is the important factor in the production of all cases of silicosis. In attempting to discover an explanation for the apparent absence of silicosis in certain localities where quartz abounds, he made comparative petrographic studies of both the rocks and the dust particles recovered from the lungs of men dying after such exposures. Where silicosis developed he found a fibrous silicate of aluminum and potassium called sericite in association with the quartz, and where there was no sericite there was no silicosis. While the argument presented by Jones is given very convincingly and his evidence seems to indicate that the presence of sericite in certain localities coincides with

From the Saranac Laboratory for the Study of Tuberculosis of the Edward L. Trudeau Foundation.

<sup>1</sup> Jones, W. R. Silicosis. *J. Chem. Metallurg. & Mining Soc. of South Africa* 34: 151 (Sept. Oct.) 1933.

<sup>4</sup> Hunter, Donald. *Lancet* 1: 897 (April 26) 1930.

the incidence of silicosis, nevertheless there are many who still doubt whether this substance is the universal cause of the disease called silicosis. In this country there are industries handling pure quartz in which numerous instances of silicosis can be detected. Experimentally, pure quartz will produce lesions essentially the same as those found in human silicosis.<sup>2</sup> Experimental tests of the action of pure sericite are in progress but it is yet too soon to expect results. For the present it seems advisable to suspend judgment on the Jones hypothesis until further evidence can be produced.

It becomes pertinent to examine the bases for the belief that only dusts of free and possibly combined silica are particularly harmful. Gye and Purdy<sup>3</sup> demonstrated that silica in colloidal form is a cell poison, which injected intravenously in large doses causes almost instant death but in smaller amounts produces proliferation of connective tissues. These authors thereupon proposed the hypothesis that particulate silica in the form of quartz is slowly dissolved in the alkaline fluids of the body, liberating minute quantities of colloidal silica, which constitutes the irritant responsible for the proliferation of the connective tissues. Chemical proof of this hypothesis is difficult, although King<sup>4</sup> believes that evidence of solution of silica in the body can be determined quantitatively by colorimetric methods. There is considerable indirect experimental evidence which favors the chemical theory of action. For example, it has been shown that the rate of reaction to particulate silica injected intravenously is inversely proportional to the size of the particles.<sup>5</sup> Particles less than 1 micron in diameter act quite like colloidal silica and cause acute inflammation and even death from necrosis of the liver within a few weeks. Particles from 1 to 3 microns in size produce progressive fibrosis in the liver with the formation of nodular lesions similar to those in the lungs caused by inhalation of silica dust. Particles from 10 to 12 microns in diameter stimulate the formation of small foreign body tubercles which do not change materially during a period of two years. Control injections of the same quantity of aluminum oxide (emery) particles cause no necrosis or proliferation of the connective tissues. Responses of this nature clearly indicate that the reaction to silica is chemical in nature.

Uncombined silica causes a very rapid necrosis of tissues, which is not produced by silicates and non-siliceous dusts.<sup>6</sup> Injection of a sufficient quantity of sufficiently fine silica particles into the skin of guinea-pigs provokes an acute exudation of polymorphonuclear leukocytes within four to eight hours. After twenty-four to forty-eight hours the site of injection becomes necrotic and is surrounded by a zone of inflammatory edema from 10 to 20 mm in diameter. The area resembles a strongly positive tuberculin reaction. Within a few days the center of the lesion ulcerates and most of the silica is eliminated in the slough that ensues.

If the concentration of silica is too low or if the particles are larger than 4 microns in diameter, the

response is less intense and no necrosis develops. The reaction excited by many of the silicates is similar, but extensive necrosis with sloughing has not been observed. Sericite, for example, produces inflammation but no necrosis, its action simulates that of granite, a mixture of silicates with quartz. Other substances containing no silica are practically inert. Such substances as diamond, coal, emery, silicon carbide, hematite and gypsum cause pigmentation of the skin with a small amount of inflammatory edema, but the latter subsides and practically disappears after twenty-four hours.

Two features brought out in these experiments are difficult to reconcile with the solubility hypothesis. The relatively insoluble quartz particles are definitely more active than the more readily soluble silicate particles and tissue reactions begin to develop so quickly that it is hard to conceive of such a solution of silica having occurred in the weakly alkaline body fluids.<sup>7</sup> It would seem that either the cellular response to silica is due to some other property than solution or that the ions liberated from free silica are more active than those from the silicates. Silica particles have a negative charge, while most other substances thus far studied are positive, but the effect of this property has never been thoroughly investigated. Obviously, further study is necessary before the mechanism underlying the irritative effect of silica can be properly evaluated.

It may appear that unwarranted emphasis has been laid on the toxic effects of silica, for the most prominent feature of human silicotic lesions is not degeneration but proliferation of connective tissue. Nevertheless the same stimulus, which in extreme concentration results in degeneration and death of cells, in a weaker form merely stimulates the growth of connective tissue. In the animal experiments reviewed, conditions have been made as extreme as possible in order to bring out in sharp relief the contrast between the response to silica and that to other particulate substances. While degenerative changes are not generally prominent in the ordinary case of human silicosis, they do occur. The centers of the hyaline fibrous nodules, where the concentration of particles is greatest, usually show definite evidence of necrosis. In the rapidly developing cases<sup>8</sup> due to the inhalation of excessive quantities of exceedingly fine particles, the bronchioles and other air spaces often contain large masses of necrotic mononuclear and polymorphonuclear leukocytes.

The prolonged inhalation of fine silica dust by white rats, rabbits and guinea-pigs results in the formation of hyaline fibrous nodules throughout the lungs and the tracheobronchial lymph nodes. While there are minor variations in the reaction in different species, the lesions are all comparable to those in human beings. Furthermore, such reaction has regularly occurred in the absence of tuberculosis or other infection, indicating that silica alone can produce nodular fibrosis. By killing animals at serial intervals during the period of dust exposure, the evolution of the pathologic process has been observed. Since the various steps are sufficiently like those disclosed in occasional autopsies of early cases in human beings, it has been assumed that similar mechanisms were involved.

7 To make sure that some solution of silica had not already occurred in the aqueous suspensions of the particles before they were injected, air-separated dust was sterilized in dry heat, suspended in salt solution and immediately injected into the skin. Reaction developed just as promptly as with the autoclaved or boiled suspensions.

<sup>6</sup> Gardner L. U. and Cummings D. E. Unreported experiments.

With this background of experimental observation, an attempt will be made to interpret the pathologic picture disclosed by the autopsy of a human case of far advanced silicosis. In the great majority of instances this picture is complicated by a coexistent tuberculosis. In South Africa, Irvine<sup>9</sup> has stated that about 75 per cent of all silicotic persons will die of tuberculosis and the same is probably true in this country. In the absence of tubercle, one usually finds a pneumonia. In the far advanced case the silicotic element is represented by discrete fibrous nodules, from 2 to 5 mm in diameter, generally black from soot or other dust inhaled with the silica, distributed throughout both lungs. In the apexes they are less numerous or absent. Sometimes the nodules, particularly in the middle part of the lungs, are embedded in a diffuse deposit of fibrous tissue radiating as a solid fan-shaped mass from one to both hili. The blood vessels and, to a lesser extent, the bronchi, have thick fibrous walls. The interlobular septums are heavy and accentuate the lobular character of the organ. The less involved air spaces are dilated and have thick walls, sometimes along the borders of the lungs there are large emphysematous blebs. Extensive pleural adhesions generally mean infection. The tracheobronchial nodes are either slate gray or black. In the earlier stages of the disease they may be soft and 3 or 4 cm in diameter, but later they often become small, hard and contracted. In the occasional case there may be small nodules in the spleen and liver, but usually the only abdominal involvement occurs in the hepatic lymph node situated near the head of the pancreas and the common bile duct.

The tuberculous element in the picture may be typical in its character and distribution, but more frequently it is not. Usually the most extensive area of infection occurs not in the apex but in the middle or lower lung. Here one may find a thick-walled cavity with evidences of extension into the adjacent lung. The process may be exudative or caseous in character, but more often it is productive with the formation of tuberculous granulation tissue in various degrees of organization, containing only small foci of caseation. Very frequently the center of each silicotic nodule presents a gray dot of caseation, while about its periphery there may be a zone of opaque pneumonic reaction. The typical picture of an apical cavity with the clustered nodules of aspiration disease in the lower lung is relatively rare. Fibrous pleurisy is the rule.

In the light of experimental observations and of the few early cases of human silicosis that come to autopsy, the evolution of uncomplicated silicosis can be depicted in the following manner. When the amount of silica in the industrial atmosphere is not too great, physiologic mechanisms are more or less effective in disposing of the inhaled particles for some years. Particles that reach the terminal air spaces are ingested by the phagocytes. The irritating silica may kill the first cell and several new ones emigrate from the fixed tissue to take its place, thereby creating a picture of cellular activity. Stimulated by the irritant, the surviving cells, each containing only a few particles, begin to move out of the air spaces into the lymphatic system. In so doing many of them pass through masses of lymphoid tissue. The phagocytes are so numerous that not all can enter and they form tubercle-like collec-

tions about the periphery of the lymphoid nodules. Silica is thus concentrated in focal areas. Many of the cells succeed in passing through into the lymphatic trunks and are either carried directly to the tracheobronchial lymph nodes or are held up in the intrapulmonary lymph nodules along the way.

The increasing concentration of silica in these locations stimulates the reticular elements of the lymphoid tissues. They proliferate, the nodule increases in size and gradually compresses the lymphatic channels. This impedes the flow of lymph and prevents effective elimination of particles, which are subsequently inhaled. The lymphatic vessels dilate because of the obstruction at their mediastinal ends and the compression at nodal points along their course through the lungs. Many phagocytes pass outward through their walls and deposit silica in the loose areolar tissue through which the vessels course. These tissues also proliferate and form a fibrous sheath about the lymphatic. For unexplained reasons the lymphatic trunks accompanying branches of the pulmonary artery seem to bear the brunt of these activities. As a result the walls of the arteries become appreciably thickened and the enlarged lymphoid nodules produce beadlike nodulations along their course.

These preliminary changes chiefly affect the lymphatic system and the tissues immediately about them. With ordinary concentrations of atmospheric dust, from three to ten years is required before this reaction is fully developed and the lymphatic system is irreparably damaged. In the generally accepted medicolegal sense, such changes are not considered as indicative of the disease silicosis but merely as preliminary alterations.

In good stereoroentgenograms of the lungs these changes are quite obvious. The linear shadows cast by the blood vessels are accentuated and extend much farther out into the lung than normally. The effect is due to proliferation of connective tissue about the lymph trunks coursing through the vessel walls. "Beading" along the vessels is caused by the formation of minute silicotic nodules in the lymphoid tissues associated with the lymphatics. The mediastinal shadow is broadened because of reaction in the nodes and about the afferent lymphatics traversing the areolar tissue outside the nodes.

When the damage to the lymphatic system is severe, inhaled particles are no longer effectively eliminated from the air spaces. The phagocytes now migrate into the peripheral framework of all parts of the lungs. The concentration of silica thus effected causes local proliferation of connective tissue cells. This occurs in the form of nodules and as a diffuse thickening of the alveolar walls. The characteristic nodular form develops because phagocytes tend to clump together, often about small peripheral masses of lymphoid tissue, and hold the silica at focal points. As time elapses, the number and size of such lesions increases. Even if the workman leaves his dusty occupation and retires to the country after inhaling a sufficient quantity of silica to produce nodulation in the parenchyma of the lung, the pathologic process will continue to progress, for the silica is no longer effectively eliminated by expectoration unless infection supervenes and, being a chemical poison, it continues to exert its effect as long as it remains in contact with the tissues.

In the first stage of the legally recognized disease, the roentgenographic examination reveals minute nodules throughout the middle portions of the lung field, often more marked on the right side. As the

<sup>9</sup> Irvine L. G. Sim on F. W. and Strachan A. S. The Clinical Pathology of Silicosis. Internat. Labor Office Report Series F. Johannesburg Conference on Silicosis (Indust. Hyg.) Geneva 1930 No. 13, p. 269.

condition progresses these nodules increase in size and blot out the previously prominent linear markings. In the second stage the nodular shadows become so large that they tend to become confluent and obscure all the normal markings. However, they still retain their uniform distribution and the outlines of the individual units are fairly well defined. Irvine<sup>10</sup> has aptly compared these appearances to the leafless tree, the tree in bud and the tree in full leaf.

As mentioned before, in some cases classified as third stage the nodules may occur in localized masses embedded in dense connective tissue. The significance of such localization is still debatable. Many observers believe that it is always indicative of coexisting infection, but in a few of the cases that have come to autopsy no evidence of an active infectious process has been discovered. Theoretically any local condition that might disturb the efficiency of lymphatic drainage in a particular part of the lung could produce such an effect. This might be caused by a preexisting pneumonia which had healed previously to the time of dust inhalation. It is also conceivable that a large focus of calcified primary tubercle formation in a lymph node might interfere with efficient lymphatic drainage. How far collateral lymphatic circulation would offset such a result has not been determined. A pneumonic process of tuberculous or pneumococcic origin, occurring early in the course of dust inhalation, would be the most obvious cause of localization. Nontuberculous pneumonias frequently fail to resolve in the presence of coexistent silicosis and organization of such a process could explain the picture. However, some of the cases that have come to autopsy with such localized lesions give no history of serious illness. Pancoast and Pendergrass<sup>11</sup> are of the opinion that localized shadows in the silicotic lung are of tuberculous origin when they extend to the periphery of the lung and that when they do not they are due to some other cause.

Under certain unusual conditions it is apparently possible for silicosis to develop rapidly, within a period of eighteen months to four years. Where the dust particles are exceedingly small and where the concentration of dust is excessive, as occurred, for example, in the process of sandblasting before the hazard of this occupation was recognized, cases of rapid silicosis were not uncommon. So many fine particles are inhaled in such a short time that the lymphatic system is entirely inadequate to remove them. As a consequence, at the same time that nodules are developing in lymphoid tissues of the lung and mediastinum, similar lesions are forming everywhere in the walls of the air spaces. The nodules are of microscopic size and there is an unusual amount of diffuse connective proliferation. The fineness of the silica renders it unusually toxic and degenerative changes are prominent. I have had opportunity to study autopsy material from fifteen such cases, in all of which death was caused by superimposed infection.<sup>8</sup> What might be the outcome had no infection occurred can be surmised from animal experiments with excessive exposure. In guinea-pigs thus exposed, the lungs are quite generally consolidated and while nodules are formed they are so embedded in the diffuse reaction that they can be seen only in microscopic sections.

Most patients with silicosis die of a complicating tuberculosis. The source of the infection may be

endogenous or exogenous. In the past it was generally believed that in most instances it originated through contacts established in the industrial environment, but it is becoming recognized that some cases develop from preexisting foci of tubercle. The clinical course of the infection is often atypical, it may not produce characteristic symptoms for a long time and can then only be diagnosed by the roentgenogram.

It manifests itself in several anatomic forms. Rarely it occurs as a healed apical scar, which has perhaps persisted for years without change. In nonsilicotic individuals such scars, according to Sampson and Brown<sup>12</sup> represent infections that have been acquired and completed their course before the age of 25. If the x-ray film of a workman exposed to dust for fifty or more years exhibits such an apical scar in a lung studded with discrete nodulation, it might be assumed that the infectious lesion is probably sterile and will never become reactivated. But there are individuals first exposed to dust after the age of 25 in whom the roentgenogram shows that such reactivation has already occurred. The upper portion of one or both lungs is involved with a massive combination of silicosis and tuberculosis, which is chronic in its course and often causes so few symptoms that it may be discovered only in routine examination of active workmen. The occurrence of such instances of reactivation makes one cautious in suggesting the possible outcome of any tuberculous lesion in the silicotic subject. The apical scar, which will remain innocuous throughout the life of an ordinary person, may harbor living bacilli in a minute focus of caseation. Experience with animals<sup>13</sup> indicates that long continued inhalation of silica may ultimately activate this focus and cause it to spread.

The more common site of tuberculosis, as already mentioned, is in the middle or lower lung. In these cases there is usually no evidence of tubercle in the apex. The roentgenogram may show fully developed silicosis with nodulation evenly distributed throughout the lungs except for a circumscribed area of confluence in the lower two thirds of one of the lungs. In the next roentgenogram, from three to six months later, this localized area has perhaps increased in size. Comparison of this film with the previous one may disclose the fact that each individual nodule throughout the lung has become larger and now casts a fluffy shadow. It is as if the nodules were kernels of corn that had popped. Such disease often continues to spread for months or even years without producing symptoms, expectoration or tubercle bacilli in the sputum. Even cavities may form without clinical manifestations. Ultimately symptoms appear, the cases are diagnosed as tuberculous and find their way to sanatoriums but usually only after a period of some years has elapsed.

Infection may supervene at any time in the course of silicosis. Not infrequently a man leaves his dusty work quite unconscious of the fact that he has acquired silicosis. The disease continues to progress and sooner or later he acquires a superimposed tuberculous infection. In the course of time, symptoms are manifested which bring him to a physician. Unless this doctor inquires carefully into the past occupational history, the important feature of a previous exposure to silica may be entirely overlooked and his condition may be

diagnosed as one of atypical basal tuberculosis with diffuse dissemination

All the types of tuberculosis thus far mentioned are chronic in their course, but acute forms are not infrequent. Acute cases are sometimes discovered in taking serial roentgenograms of groups of workmen employed in silica industries. On the first examination the film may show a generalized nodulation with a small localized shadow at one point. Two or three months later this shadow will be seen to have increased in size and perhaps many of the nodules in other parts of the lung no longer cast clearly defined shadows. A cavity may form in the original focus and subsequently obvious evidence of infection develop elsewhere. In one such case recently observed, death from generalized pulmonary tuberculosis occurred six months after the first localized shadow, no larger than the thumb nail, was detected. This man, apparently well at the time, later showed fever and other symptoms of intoxication but tubercle bacilli were never found in smears of the sputum. He came to autopsy and the lungs exhibited a typical picture of silicosis with tuberculous pneumonia, but bacilli could be found only after prolonged search.

The pathology of the tuberculous complication has been discussed from its roentgenologic aspects because by this method the evolution of the process can be followed. Histologic examination of the terminal stage seen after autopsy may confirm the diagnosis, and it permits differentiation between silicotic and tuberculous foci. Usually the tuberculous lesions are of a productive type consisting of cellular granulation tissue, which shows a marked tendency toward organization. Such reaction surrounds silicotic nodules so that they become embedded in scar tissue. Caseation and cavity formation occur, but degenerative changes are not always prominent. Such involvement obviously results from extension through the lumen of the air spaces and it merely surrounds any silicotic nodules that happen to be present. In addition, the centers of nodules remote from pneumonic areas frequently contain minute points of caseation. Such a manifestation could be due to dissemination of bacilli through blood or lymph vessels. The lymphatics seem less likely to be the channel of infection, for usually their lumens are completely obliterated. Included blood vessels are also greatly constricted but many of them are potentially patent and could carry organisms into the nodule. In acute cases such as the one described the tuberculosis is of the caseous pneumonic type.

The specific cause of the unusual susceptibility of the silicotic lung to tuberculous infection is not known. The phenomenon can be duplicated in the experimental animal and certain aspects have been studied in detail. Kettle<sup>14</sup> showed, for example, that bovine tubercle bacilli injected intravenously into ordinarily nonsusceptible white mice would localize and multiply without restraint in foci where large quantities of silica had been injected. I<sup>15</sup> have demonstrated that guinea-pigs infected with attenuated tubercle bacilli and then exposed to the inhalation of quartz dust develop a very chronic but fatal form of silicotuberculosis, whereas in normal animals the same infection completely heals and disappears. The effect is not due to changes in the bacilli for when portions of the lungs of the infected silicotic guinea-pig are subinoculated into normal ani-

mals the infection is not progressive. The same result can be obtained by infecting silicotic rabbits with human tubercle bacilli, a type which ordinarily does not produce progressive disease in this animal. All of these studies have merely shown that tubercle bacilli grow better in silicotic soil than they do in normal animal tissue. Cummins<sup>16</sup> suggests that the obstruction of the lymphatic system mechanically prevents elimination of bacteria from the lung, but this will not explain the selective localization and proliferation of intravenously injected bacilli in an area of silicotic reaction in the groin. Studies are now in progress to determine whether there is a disturbance of the mechanisms of immunity in silicosis.

The modifying effect of other substances inhaled with silica probably deserves more attention than it has thus far received. It is claimed that the presence of free alkali accelerates the solution of silica and hence promotes more rapid tissue changes. A considerable number of these rapid cases have been reported among young women packing siliceous scouring powders, but their similarity to the disease in sandblasters and others wherein there was no alkali suggests that the excessive exposure to fine dust may have been responsible.

On the other hand, certain other substances seem to retard or prevent silica from exerting its usual effects. The lesions of silicosis in the anthracite coal miner<sup>17</sup> and the hematite miner<sup>18</sup> are often quite atypical even though the concentrations of silica to which these men have been exposed may have been high. Coal and hematite alone tend to produce subpleural and perilymphatic pigmentation with the formation of considerable cellular connective tissue in these locations. The parenchyma of the lung suffers little damage and no nodules are produced. When a little silica is inhaled with these substances, the connective tissue tends to become more dense and hyaline in character but still retains its perilymphatic distribution. If the amount of silica is still greater, nodules form along the lymphatic trunks. Only when silica predominates do nodules develop in the parenchyma of the lung, but even these nodules lack the clear cut definition of the uncomplicated silicotic lesion. They are surrounded by wide, stellate zones of deeply pigmented cellular connective tissue. How far the tuberculous complication may be influenced by coal, hematite and other dusts is still debatable. Considerable evidence is available to suggest that it is not so apt to become progressive as among workers in pure silica.

The effects of the silicates cannot be considered here except to state that the lesions of asbestosis are not nodular but diffuse in character. This is probably due to the shape and character of the particles, which in consequence are not concentrated at focal points by the phagocytes. Tuberculosis is not so invariably the cause of death in the case of asbestosis, although numerous cases have been reported in which it has caused death.<sup>19</sup>

#### SUMMARY

Dusts containing silica are preeminently dangerous. Present knowledge will not permit it to be said that only free silica is harmful, possibly some of the sili-

cates will also be incriminated. One silicate, asbestos, produces a characteristic and dangerous type of pulmonary fibrosis. Silica is a tissue poison. In low dilutions it causes nodular fibrosis, in higher concentrations it produces rapid necrosis of cells of all kinds.

Human silicosis begins by damaging the pulmonary lymphatic apparatus and is followed by the development of nodular fibrosis of the parenchyma of the lungs.

Silicosis specifically predisposes to infection with the tubercle bacillus. The mechanism of this action has not yet been determined. It probably consists in some alteration in the soil rather than in changes induced in the infecting organism.

Nonsiliceous dusts localize about the lymphatic trunks and some of them excite the proliferation of small amounts of loose cellular connective tissue. They apparently do not increase susceptibility to tuberculosis.

Nonsiliceous dusts inhaled in combination with silica modify the action of the latter, altering the anatomic characteristics of the lesions and apparently decreasing the susceptibility to tuberculosis.

## Clinical Notes, Suggestions and New Instruments

### GONORRHEAL PROSTATIC ABSCESS IN FOUR YEAR OLD BOY

CLAUDE P. FOX, JR., M.D., GREENEVILLE, TENN.

Gonorrhea in the male child is considered rare, or very rare, by most authorities, and not a great many cases have been reported in boys at or before puberty. Squires reports five cases of gonorrhea in male children ranging in age from 5 years to 12 years. Bierbach reports two cases in young boys whose respective ages were 3 and 6 years. Wolbarst, within two years, saw twenty-two cases of gonorrheal infection in boys ranging from 18 months to 12 years of age. Textbooks make little or no mention of gonorrhea in male children although its comparative frequency is recognized in female children. Unquestionably the condition is much rarer in young boys than in young girls.

Most authorities who report cases emphasize the fact that gonorrheal infection in children is accompanied much less often by complications than is the infection in adults. This is presumably due to the fact that children are much less likely to have the irritations of sexual excitement and alcoholic excesses than are adults. In fact, in a recent issue of *THE JOURNAL* it was stated<sup>1</sup> in answer to a query concerning a 6 year old boy with gonorrhea that the condition should clear up rapidly without complications if no traumatic treatments were given, because children are not subject to the chief causes of complications and chronicity, namely, sexual excitement and alcohol.

Some authors report cases of complications with and without local treatment. The complications thus reported have been phimosis, lymphangitis of the penis, prostatitis, inguinal adenitis and epididymitis. As far as could be determined by a review of the literature, none have reported an instance of prostatic or periurethral abscess and most declare that the infection clears up rapidly.

The case reported here may be considered unusual because of its chronicity and complications, in a very young child who was subjected to none of the influences ordinarily considered as causative of complications and chronicity.

#### REPORT OF CASE

H. H. J., a boy, aged 4 years, seen Aug. 18, 1932, was brought by his parents because of painful urination and swelling and redness of the penis.

At my first observation the glans and prepuce of the penis were inflamed and edematous and there was a profuse yellowish white discharge from the urethra. A smear was made of this discharge and many pus cells with a great many gram negative intracellular diplococci, morphologically identical with gonococci, were found. At this time the condition did not appear so serious. The child was placed on small doses of methenamine internally and the parents were instructed in the method of cleansing the penis with a mild antiseptic solution. No injection was prescribed or used.

In a day or two the patient was brought back with a severe paraphimosis, with great constriction of the penis behind the glans and very marked edema of the glans and prepuce. This paraphimosis could not be reduced and urination had become so difficult that it was necessary to incise the constricting band. This resulted in a subsidence of the swelling in a few days and urination became more normal.

The urethral discharge continued freely for two weeks and then subsided, but pus and gonococci continued to be present in the urine in large numbers. The inflammation and swelling of the glans and prepuce also had practically disappeared in two weeks. There was then no evidence of trouble except in the urine until September 27, when the child began to have pain in the perineum when sitting down or walking. He was then admitted to the Greeneville Sanatorium and Hospital.

There was a very tender mass about the size of an English walnut in the midline of the perineum. The skin over this mass was reddened and edematous and there was slight fluctuation. There was no urethral discharge and no swelling or inflammation of the prepuce or glans. The urinary examination revealed many pus cells and gram-negative extracellular diplococci and a few gram-negative intracellular diplococci. On admission the temperature was 100 F.

After admission to the hospital the pain and tenderness in the perineum became progressively worse and the mass became larger and more fluctuant. The temperature rose to 102. It was decided to incise the mass and on September 30 this was done under general anesthesia. A large amount of thick yellowish white pus was evacuated through a median perineal incision. The abscess cavity was mostly on the right of the midperineal line and extended back to the arch of the pubis. A smear of the pus showed many gram-negative intracellular diplococci morphologically identical with gonococci.

The condition of the child rapidly improved following the incision and in three days his temperature reached normal, where it remained thereafter. The pain and inflammation rapidly subsided in the perineum but there was more or less drainage for several weeks. The patient was able to return to his home seven days after the operation.

He, however, was kept under observation until January 1 and repeated examinations of his urine were made. There was a decrease in the pus cells and diplococci but on the last examination in this period a few gonococci were found.

Some time before this the perineal incision had entirely healed. The general and local condition of the child had so markedly improved that his parents ceased to bring him for examinations.

He was again seen on May 5, 1934, about twenty months after the gonorrheal infection began. At this time his urine was free from pus and bacteria and the local parts were normal except for the prepuce, which was redundant.

#### COMMENT

At no time was this 4 year old child given any urethral injection, nor was any sound or other instrument passed into the urethra, yet his gonorrheal infection lasted for at least five months. The abscess that was opened in the perineum was gonorrheal and came from the prostate, most probably, because there was never any periurethral extravasation of urine or leakage of urine through the perineal incision.

The source of infection could not be determined definitely, but the mother stated that the boy had been playing with a little girl, of about his own age, who was known to have gonorrheal vulvovaginitis. Handling of the penis sometimes resulted in erections, and it is very likely that infection was derived from sexual contact with the girl.

<sup>1</sup> Gonorrhea in a Six Year Old Boy. *Queries and Minor Notes*. J. A. M. A. 101: 1903 (Dec. 9) 1933.

This possible precocious sexual development of the boy may have been a factor in causing his complications and the chronicity of the case. Wolbarst and other writers now incline to the idea that gonorrhea in children is more commonly due to sexual contact than is generally supposed, and this certainly would be a rational conclusion in boys, in whom the opening through which infection must take place is so small.

## Therapeutics

### THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.  
CHICAGO

NOTE—In their elaboration these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics Dr. Bernard Fantus. The views expressed by various members are incorporated in the final draft for publication. The series of articles will be continued from time to time in these columns.—ED

#### THERAPY OF BARBITURATE POISONING

In barbiturate poisoning the phenomena of excitation, even up to tonic spasms and trismus, are rare. They are present only after relatively small toxic dosage. Recovery is the rule. Heroic administration of sedatives in such cases with excitation may cause death.

Usually the patient arrives at the hospital in coma, with the reflexes and pupillary reactions retained or even exaggerated. While the barbitol pupil is usually dilated with normal or slightly delayed pupillary reaction (and it is small and reactionless only in extreme cases), the pupil of morphine poisoning is generally small and becomes dilated only shortly before death. A test for barbitol in the urine that clinches the diagnosis is made by acidifying it and shaking out with ether, which leaves, on evaporation, large crystals that melt at 190 C.

The fatal dose is, in general, from fifteen to thirty times the therapeutic dose. The nearly always fatal dose of barbitol is about 10 Gm, of phenobarbital about 4 Gm and of dial about 2.4 Gm. The mortality rate may exceed 20 per cent. Barbiturate poisoning generally continues for several days before death or recovery takes place.

Treatment requires the recognition of two stages: the stage of coma and the stage of reaction.

**Stage of Coma**—1. Evacuation of the stomach, with the patient's head lower than the stomach (best carried out on the operating table) is done to prevent aspiration of fluid overflowing from the stomach around the tube, with subsequent development of aspiration pneumonia. If trismus is present the duodenal tube should be passed through the nose. The stomach should be washed thoroughly with diluted (pink) permanganate solution. Lavage is indicated even when the poison was taken many hours previously. To clear unabsorbed poison from the bowel, Magnesium Sulphate (60 Gm) should be left in the stomach with Fluidextract of Cascara (16 cc). The tube should be left in place. If no bowel movement is secured, this should be followed in a few hours with a full dose (240 cc) of Compound Infusion of Senna, and, if this fails, a bombardment should be kept up with 30 cc of Castor Oil at intervals of four hours until bowel evacuation is secured. Enemas may

be required in addition, and these might well consist of hot strong, black coffee, any quantity of which retained also serves as an antagonist.

2. Postural drainage should be maintained continually. The foot end of the bed is elevated to tilt the bed from 15 to 20 degrees, the patient's feet being tied to the end of the bed if necessary, and the patient's head turned to the side. Secretions accumulating in the pharynx should be removed by suction.

3. Feeding should be done through the stomach tube, at intervals of every four hours, with two cupfuls of not excessively hot, strong coffee with some milk. When a feeding is due, the stomach should always be evacuated of its contents before injection of the feeding that is due, so as to avoid overdistention of the stomach and possible overflow around the tube and aspiration into the lungs.

4. Antagonists should be given in heroic doses, liberally and in rotation. Caffeine in the form of warm black coffee by rectum or of Caffeine Sodio-Benzozate, 0.5 Gm, intramuscularly every two hours up to 1 Gm, repeated after a rest period, and Metrazol, 2 cc of 10 per cent solution intravenously and 2 cc intramuscularly at the same time. This dosage may be repeated from every thirty minutes to one hour. Strychnine nitrate, 2 mg hypodermically every hour or two, should be given until there is increased reflex excitability.

5. Elimination should be assisted by 5 per cent dextrose phlebotomy to maintain free secretion of urine. This may be helped by a xanthine diuretic. (a) Aminophylline (theophylline ethylenediamine) in doses of 0.25 Gm in 10 cc of water, which may be given in the dex-

#### PRESCRIPTION 1—Theophylline Suppositories

R. Theophylline	2.50 Gm
Oil of theobroma	17.50 Gm
Mix and divide into ten suppositories	One every four hours

trose infusion, possibly every eight hours. (b) If this is not available, suppositories containing Theobromine Sodio-Salicylate, 0.5 Gm, or preferably Theophylline, 0.25 Gm (prescription 1), may be administered four or more times daily. Catheterization should be done every four to six hours.

6. The body temperature should be kept from falling below the normal by the application of external heat with great care to prevent burns. In conditions of sub-normal temperature, heat is the greatest of all stimulants, it is a requisite to permit medicinal stimulants to act properly, and it may prevent the lowering of resistance that favors the development of pneumonia.

7. Artificial respiration with oxygen inhalation should be instituted on the appearance of marked enfeeblement of respirations. Death from primary paralysis of respiration is, however, very rare. Death from primary circulation failure occurs only in cases in which the heart is diseased.

**Stage of Reaction**—Usually by the end of the first day the temperature rises, respiration becomes embarrassed, pneumonic foci or pulmonary edema develops, the blood pressure falls and the pulse becomes enfeebled. These pulmonary sequelae are probably in most instances the result of the general vasoparesis with or without subsequent infection. Nevertheless, everything should be done to prevent the possibility of a suspicion that they are due to aspiration or to chilling. The treatment is that of pneumonia (q.v.).

Great tendency to decubitus (q v), also due to vascular paresis, requires special precautionary measures

Constant nursing care is imperative to give these desperately sick and helpless patients their best chance for survival

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING ARTICLE  
H A CARTER, Secretary

### RESUSCITATION

YANDELL HENDERSON, PH D  
NEW HAVEN, CONN

The art of resuscitation<sup>1</sup> has made great advances during the past twenty years both in theory and in practice. These advances will be briefly reviewed here. There are also some developments to report, so recent that they have not yet reached practical application, and some further developments are indicated as probable during the next few years. Such developments deserve encouragement, for there are still large possibilities of improvement in the field of resuscitation. The chief objects of this article are three

1 To promote the widest possible use of those measures and devices that have been proved by experience to be safe and effective

2 To give warning against the use of drugs and apparatus that, instead of benefiting, may injure patients or may even result in loss of life

3 To show that the facts of resuscitation largely refute the theory of asphyxia that is now generally accepted, and to promote the development of sound theory as a basis for further progress in the art of resuscitation

#### FORMS AND DEGREES OF ASPHYXIA

Resuscitation is the therapeutics of acute asphyxia. The causes and forms of asphyxia, both acute and chronic, are many, and their treatment should vary to correspond with their differences. They include drowning, electric shock, carbon monoxide poisoning, neonatal apnea and atelectasis, anesthetic and postoperative depression, mountain sickness, aviators' collapse, and the impairment of the lungs by irritant gases and by pneumonia. Indeed, the terminal stages of most of the various ways of dying—the stages when the circulation and respiration are failing—are largely asphyxial.

Short of death there are also three degrees of asphyxia. They differ in the duration and intensity of the asphyxia. According to their outstanding features they are apneic asphyxia, acarbic asphyxia and chronic asphyxia.

*Apneic Asphyxia*—Brief but intense asphyxia, under complete deprivation of oxygen, is exemplified in drowning. Its outstanding feature for treatment is apnea cessation of breathing. The vital machine is little damaged. It is merely stopped. It is restarted mainly by means of artificial respiration. Inhalational treatment is secondary, although it is often of critical value for the saving of life. If recovery occurs at all, it is generally rapid and complete.

*Acarbic Asphyxia*—More prolonged but less intense asphyxia is exemplified in those cases in which sublethal atmospheres of carbon monoxide have been breathed for several hours. The patients are often still breathing, although in profound coma, when removed from the poisonous atmosphere. The vital machine has been so deranged by asphyxia that, without treatment, recovery is slow and painful. There may be sequelae of mental or physical incapacity, indicating profound tissue damage especially in the nervous system, or even subsequent death. In such cases artificial respiration is often not needed, as breathing has not stopped. But if further damage is to be prevented and recovery is to be rapid, inhalational treatment is essential. Prolonged acute deprivation of oxygen through any agent or process induces this type of asphyxia. But restoration of oxygen alone does not cure it or cures it only very slowly. Experience has shown that for rapid restoration of normal conditions the effective means, along with oxygen, is inhalation of carbon dioxide in proper dilution. In the benefits of this inhalation the stimulation of respiration is important, but the deeper effects of carbon dioxide on the conditions in the blood and tissues, particularly the relief of acarbica (defined below), are equally or even more important.

*Chronic Asphyxia*—In addition to these two forms of acute asphyxia there is also a third or chronic asphyxia due to a partial deprivation of oxygen. It occurs in anemia and in heart disease and is characterized by shortness of breath and continual oxygen debt. Restoration of red corpuscles and prolonged inhalation of oxygen<sup>2</sup> are the logical treatments.

The fundamental processes occurring in all forms of asphyxia are as yet but incompletely understood or, rather, they have been generally misinterpreted. They have been variously termed acapnia, acidosis and acarbica deficiency of carbon dioxide, excess of acid and diminution of the amount of alkali bicarbonates in the blood. This much only is clear. Deficiency of oxygen induces a profound disturbance of the state in which carbon dioxide is normally held in the body and in its amount. I shall call this state "acarbica." It is the state generally called "acidosis" and mistakenly regarded as an intoxication by acid<sup>3</sup>. Restoration of the supply of oxygen overcomes this state but slowly. If injury to the tissues has not gone too far, restoration of carbon dioxide by inhalation, together with adequate oxygen, rapidly and completely restores normal conditions in the body.

#### ARTIFICIAL RESPIRATION AND INHALATIONAL APPARATUS

In such states as the complete apnea induced by submersion in water or by electric shock, even seconds are precious. Death will quickly result unless the supply of air to the lungs is immediately renewed. The prompt application of artificial respiration is therefore the measure of primary importance and for this purpose the

prone pressure method introduced by Schafer<sup>4</sup> is the procedure of choice. It should always be continued until natural breathing returns or rigor mortis sets in. Lives have been lost by physicians interfering with the policeman, fireman or boy scout who was performing artificial respiration. It is easy to order a nonbreathing victim of drowning or electric shock or other acute asphyxia into an ambulance, but he will be dead before he reaches the hospital.

In using the Schafer method or any other form of artificial respiration, on a victim of drowning, the question of removing water from the lungs may be disregarded. If the body has been in fresh water, the water that reaches the lungs is quickly absorbed into the blood. If salt water is involved, the absorption is slower. But in either case there is really no way to get the water out of the finer tubes and chambers of the lungs by manipulation. If all of them are occluded, the circulation of the blood through the lungs is believed to be obstructed in a manner similar to Valsalva's experiment and death is immediate by so-called immersion shock. Fortunately there are generally enough spaces in the lungs still free from water to permit sufficient ventilation under artificial respiration to supply that minimum amount of oxygen which is necessary to maintain life. If life is thus maintained the victim is generally resuscitated, provided of course that the heart is still beating and the blood circulating.

Artificial respiration is also the measure of primary importance in electric shock, although it is effective only in cases in which respiration, but not the heart, has been stopped. If the heart has been thrown into fibrillation, no means now available can restore a coordinated pulsation and resuscitate the victim. There is distinct experimental progress toward restoration of coordinated heart action after electric shock,<sup>5</sup> but there is as yet no practical application of such laboratory observations requiring discussion here. If the heart has not been thrown into fibrillation, but only respiration is stopped, recovery under artificial respiration is brought about essentially as in cases of immersion.

In connection with artificial respiration, three recent practical developments deserve mention. One is the tilting board developed by Eve<sup>6</sup> in England and by Cornish<sup>7</sup> in California. This device is in principle a seesaw on which the victim is laid and rocked slowly through an angle of 30 degrees or more from the horizontal each way. Adjustable pegs are placed in holes in the board at the shoulders and feet to keep the body from sliding. When the head is lowered and the feet are raised, the weight of the abdominal viscera acts on the diaphragm to induce expiration. When the head is raised, the movement of the viscera and diaphragm feetward induces inspiration. If the body is completely flaccid, the victim should be laid on his face so that the tongue will fall forward, otherwise on his back. The device is quite easily constructed by any carpenter and would probably prove useful at bathing places and in the accident rooms of hospitals for use in cases of concussion, morphine poisoning and other conditions of

hypopnea and apnea. An apneic baby has been revived with it. It is also particularly adapted to use by laymen.

An apparatus for prolonged artificial respiration by compression of the chest has recently been described by Kerridge.<sup>8</sup>

The other development is of a different type, it is for use by physicians only. It is the device, recently developed by Flagg,<sup>9</sup> to facilitate the introduction of a sound into the trachea for the administration of intratracheal insufflation. It consists of an electrically lighted laryngoscope. Because of the flaccidity of the muscles of the mouth and throat in the victims of drowning and in asphyxial new-born babies, the larynx is readily made visible with this device and a tracheal sound is easily introduced. Through this sound a mixture of oxygen and carbon dioxide may be blown directly into the lungs. The principle involved is essentially that of artificial respiration by intermittent insufflation, as introduced by the late Dr. Meltzer.<sup>10</sup> There can be no doubt that some victims of submersion, of neonatal apnea and of collapse under surgical operations, particularly in the thorax, who can be resuscitated in no other way can be saved by this means. The apparatus will be useful as an attachment of the inhalator at large bathing places, such as Coney Island, where enough drowning and other accidents occur to justify regular medical attendants. The number of cases of drowning and of asphyxia of the new-born needing insufflation is, however, small compared to those needing only inhalation. The capacity of the apparatus to induce dilatation of the atelectatic lungs, especially in cases of birth shock and asphyxia pallida, contributes a marked advantage over simple inhalation, but it should be used with precautions against excessive intrapulmonary pressure. These precautions consist in setting the blow-off valve at not more than 25 mm of mercury pressure. For the adult, 40 mm is allowable.

The report of a referee of the Council on Physical Therapy indicates that in its present form the Flagg laryngoscope is somewhat too large for convenient use on infants and that the metal cannulae will also need some modification to prevent trauma. These are however details that can be easily improved. The revival of intratracheal insufflation for clinical use is a valuable contribution to the art of resuscitation.

During surgical operations in the thorax there is sometimes urgent need for artificial respiration. Apparatus of the general type used in physiologic laboratories would meet this need, if combined with intratracheal insufflation. Such an apparatus has recently been devised by Coryllos.<sup>10a</sup>

Reports based on the practical experience of obstetricians indicate that, in the mixtures of oxygen and carbon dioxide used for resuscitation of the new-born, high percentages of carbon dioxide—up to 20 or even 30—are found most effective for the initiation of spontaneous breathing in difficult cases but that, after spontaneous breathing has been established, percentages of 7 or 8, or even as low as 5 are sufficient. Such is the testimony of the referees to whom the Council on Physical Therapy has referred the infant resuscitation apparatus recently submitted for testing. It is probable

that a high initial carbon dioxide mixture followed by a lower mixture would also be the most effective agents for resuscitation in cases of drowning. On theoretical grounds it would seem to me that both for the new-born and for the drowned 20 per cent of carbon dioxide in the stronger mixture and 7 per cent in the weaker should be enough. But, of course, practical experience, not theory, must determine the final decision.

For administering inhalation in all varieties of cases of asphyxia, the H-II Inhalator,<sup>11</sup> with the recent addition of a Flagg device, affords in general the best means of stimulating respiration after submersion, electric shock and carbon monoxide asphyxia. Several thousand of these inhalators are now in use with a very large saving of life. The Davis Inhalator<sup>12</sup> also has been approved by the Council on Physical Therapy. The infant resuscitators of the Ohio Chemical and Manufacturing Company<sup>13</sup> and of the Foregger Company<sup>14</sup> have both been found efficient and have recently received the approval of the Council on Physical Therapy. Both of these companies supply also excellent inhalators for administering carbon dioxide (from cylinders of liquid carbon dioxide) mixed with air in an open mask. The first, third, fourth, fifth and sixth of these appliances are made according to my designs.

The Sparklet Resuscitator, now advertised in medical journals, has possibilities of usefulness that have not as yet been developed to a point deserving of approval by the Council. The amount of the oxygen carbon dioxide mixture that one of the Sparklets affords is so small that it can be used effectively only for total rebreathing. But, used in this way, it should be valuable for the treatment of asphyxial new-born babies delivered in private homes. The amount of liquid carbon dioxide contained in a sparklet would be sufficient to stimulate respiration for a few minutes if the control apparatus regulated the flow effectively. But such is not now the case.

The Pulmotor<sup>15</sup> has been condemned so frequently in reports by committees of high scientific competence that, except for its name, it would long since have passed, as it should, into the limbo of things forgotten. Unfortunately the word "pulmotor" has become in popular speech a generic term for any and all respiratory and resuscitative devices and particularly for an inhalator. Because of this confusion of terms, the newspapers often report the resuscitations effected by means of inhalators as cases of "victims restored to life by the Pulmotor." Then some ill informed community buys one of these discredited devices for its fire department.

Recently another device has been brought out and vigorously promoted by sales agents, which is in all essentials, simply another pulmotor. As it is intended for use by laymen, it applies mechanical artificial respiration by means of a mask. It has, therefore, the same disadvantages as the original pulmotor, namely, leakage from the mask, inflation of the stomach, possibility of injury to the lungs by overdistention, and

rapid and inefficient reversal of inspiration and expiration. If set to produce low pressures, such apparatus is ineffective, if set to high pressures, it is likely to injure the lungs. The apparatus has an inhalation attachment, but the airways are too small for full efficiency in supplying oxygen and carbon dioxide for natural breathing. This defect could be corrected, the pulmotor feature should be eliminated. The name of this device is the E and J Resuscitator. The inventors of apparatus of this type should learn that mechanical artificial respiration apparatus employing pressure and suction with a mask cannot be made effective with a mask or safe for use outside a laboratory or a hospital. Pressure and suction require intubation of the trachea, an operation that properly and legally can be performed only by physicians. The administration of pressure and suction with a mask sometimes works, but it is liable to fail when most needed. In the hands of laymen, such apparatus cannot be made free from serious danger of injury to the lungs.

A device for artificial respiration of a quite different order is the Drinker apparatus<sup>16</sup> and one of the same type offered by Emerson.<sup>17</sup> In such apparatus the entire person of the patient is enclosed in a steel chamber with the exception of the head. A rubber collar fits airtight, but comfortably, around the neck and intermittent suction, or alternating suction and pressure with precautions against excessive forces, are applied to the body within the chamber. The device finds its usefulness in maintaining artificial respiration for periods of days or weeks in cases of poliomyelitis with severe respiratory involvement. It has been used successfully in cases of neonatal apnea and atelectasis but appears to offer no considerable advantages over simple inhalation of oxygen and carbon dioxide in the easier cases of asphyxia of the new-born or over the Flagg technique in extreme cases. In the new-born the object is not, as in poliomyelitis, to supply prolonged artificial breathing but rather to get the child to breathing for itself.

The oxygen tents, now used in cases of pneumonia, have also possibilities of value, as yet undeveloped, as resuscitation apparatus, particularly in cases of extreme hemorrhage.

The lack of apparatus for measuring respiration is now one of the greatest deficiencies in medical technique. Measurement of respiration—in the sense of the volume of air breathed in liters per minute—is quite as important as a guide to prognosis and treatment in many disorders as is measurement of arterial pressure. The apparatus now used for determining basal metabolism could easily be modified to serve also as respirometers.

All subcutaneous, intravenous or intracardiac medication is harmful rather than beneficial in asphyxia.<sup>18</sup> Oxygen administered subcutaneously is absorbed too slowly to be helpful.<sup>19</sup>

#### CONFLICTING THEORIES OF ASPHYXIA<sup>20</sup>

In the development of resuscitation, practice has outrun theory. Resuscitation by means of carbon dioxide

is now justified mainly by the incontrovertible fact that in many forms of asphyxia this treatment is highly effective in saving life. But this fact is not greatly reinforced by theory. On the contrary, it has had to meet an extraordinary succession of obstacles in the form of adverse theories. Plausible theories are not easily refuted by facts unless the facts are reinforced by equally plausible alternative theories. In this case the principal obstructive theory is very plausible and very firmly intrenched, it is one of the foundations of modern biochemistry. The alternative theory is as yet crude and incomplete—a mere beginning for a sound conception of asphyxia.

When I<sup>21</sup> first proposed inhalation of carbon dioxide twenty-five or thirty years ago, the gaseous excretion, carbon dioxide, was still regarded as the physiologic opposite of oxygen. Its use in asphyxia or in any condition related to asphyxia, such as postoperative depression, was directly contraindicated. Asphyxia was considered to involve not only lack of oxygen but also excess of carbon dioxide and obstruction or stoppage of breathing. Investigations in this laboratory showed, on the contrary, that in carbon monoxide asphyxia there is excessive breathing and decrease of carbon dioxide. Low oxygen, low carbon dioxide and hypernea are concomitants in mountain sickness, in anesthetic depression and in other states related to asphyxia. In all such states, overbreathing and the development of a deficiency of carbon dioxide are among the conditions inducing the final depression and failure of respiration.

The demonstration by Haldane<sup>22</sup> and his collaborators of the preeminent part that carbon dioxide plays in the regulation of respiration in man facilitated the introduction of carbon dioxide as an agent by which anesthetists may control the breathing of patients under operation. But my advocacy of this use of carbon dioxide was based not merely on the control of breathing but to a greater extent on certain experimental observations on animals in this laboratory. These observations were that after anesthesia and operation the amount of carbon dioxide in the blood is diminished and that, contrariwise, conservation of the body's store of carbon dioxide largely counteracts postoperative depression of the circulation. The low carbon dioxide content of the blood was regarded as a form of apnea.

Almost simultaneously, another theory<sup>23</sup> based on quite different grounds developed in biochemistry. Under that theory, as commonly interpreted and applied, inhalation of carbon dioxide after asphyxia or in any related condition would have been absolutely prohibited. It would intensify the acidosis that even a slight degree of asphyxia was supposed to induce.

This biochemical theory was beautifully clear and complete. It was based on the principles of physical chemistry. It afforded an apparently perfect theory of asphyxia and of acidosis. According to that theory asphyxia develops as follows: Combustion in the tissues of the living body is first anaerobic, sugar

breaks up into lactic acid. Under normal conditions, part of this lactic acid undergoes combustion, the remainder was supposed to be reconverted into sugar. Under oxygen deficiency, however, some of this lactic acid failed to be either burned or converted back to sugar. This acid then reacted with the alkali bicarbonates of the blood, neutralized them and thus decreased the carbon dioxide content and alkalinity of the blood. Asphyxia led to acidosis, and acidosis was acid poisoning.

In close accord with the requirements of this theory, it was demonstrated that a low  $p_H$ , low alkali bicarbonates and a considerable increase of lactic acid in the blood do occur in the terminal stage of asphyxia and of all related conditions. Biochemists therefore gave warning that inhalation of carbon dioxide, which is the anhydrous form of carbonic acid, must intensify asphyxial acidosis dangerously, perhaps even fatally.<sup>20</sup>

Faced with such opposition—then theoretically insurmountable—resuscitation by inhalation of carbon dioxide could be introduced only clinically, and lives thus saved by avoidance of theory. My discussions of practical means of resuscitation dealt strictly with facts. No well rounded alternative theory was—or is even now—available. With this suppression, inhalation of carbon dioxide was successfully introduced into the surgical field, where it soon proved its usefulness. Its success was complete in the nonmedical field of carbon monoxide asphyxia, where treatment is administered by the rescue crews of city fire departments and theory offered no obstacle.

The justification for such unconventional disregard of theory and the authorities lay strictly in facts. It was found in experiments on animals in this laboratory that so-called asphyxial acidosis differs profoundly from a true acid intoxication. The alkali of the blood is not lost from the body in asphyxia, nor is it permanently neutralized, it is merely rendered occult. Dogs that had been made truly acidotic by intravenous injection of dilute hydrochloric acid were quickly overwhelmed, or even killed, by inhalation of carbon dioxide. On the other hand, animals rendered pseudo-acidotic, or acarbic, by asphyxia were quickly restored to a normal condition by such inhalation. And at this point a fact was discovered that may afford a beginning for a sound theory of asphyxia. This fact is that inhalation of carbon dioxide, instead of intensifying acidosis<sup>24</sup> in an acarbic animal or man, quickly recalls the alkali bicarbonates in the blood to their normal amount.<sup>25</sup> In this respect carbonic acid (i. e. carbon dioxide) differs from such acids as hydrochloric. The latter would kill at, or above, a point ( $p_H$  7.0) to which the blood of an asphyxiated man, animal or new-born baby may be acidified with carbonic acid with no harm whatever during resuscitation.

This mobilization of alkali under the influence of carbon dioxide in the presence of oxygen is a vital reaction occurring not only in animals but even in plants, such as the potato. The contrary reaction occurs in men and animals during the development of asphyxia. Under deficiency of oxygen the carbon dioxide in the blood is also diminished, and following this diminution a considerable part of the blood alkali is somehow neutralized or immobilized. It is highly significant that this sequence occurs not only during the development of asphyxia under carbon monoxide but equally in the asphyxia of a baby before birth. The

former can lose carbon dioxide through the lungs, the latter cannot. The orthodox theory, which fails in respect to these matters, has failed also, it may be noted, in others. It has failed particularly in respect to the value of alkaline therapy in diabetic acidosis, and extensive revision has been needed in respect to the part supposedly played by lactic acid in muscular contraction. So fallible a theory should not be allowed longer to interfere with the saving of human life.

#### CONTRASTING INFLUENCES OF OXYGEN AND CARBON DIOXIDE<sup>20</sup>

Even when the obstacle of "acidosis" had been in practice largely surmounted, or at least circumvented, a third theoretical obstacle remained. Until quite recent years this imaginary "lion in the path" has blocked the application of carbon dioxide to what should be its most important field—resuscitation of the asphyxiated newborn. Surely—so it was argued—an asphyxiated baby or drowned adult must have already a supernormal respiratory stimulus in its blood. Because of the accumulated carbon dioxide, lowered  $p_{\text{H}}$  and increased lactic acid in its blood, it should not need any additional stimulus. How, then, could one justify administration of carbon dioxide in cases of asphyxia neonatorum?

It happened however that, in cities where inhalators were available, many babies were resuscitated by the rescue crews of the fire departments, called in by physicians after all the ancient procedures—slapping, swinging, and dipping in cold water—had failed. For a time even the hospitals invoked this aid. Now the large majority of hospitals are equipped with inhalational apparatus and cylinders of carbon dioxide diluted to various percentages in oxygen.

These facts forced a reconstruction of theory with the result that, in this laboratory at least, a conception that has been recently widely current in physiology was rejected. That conception was that the  $p_{\text{H}}$  of the respiratory center itself was the dominant factor in the control of breathing and that it is through this factor that both oxygen and carbon dioxide act.<sup>23a</sup> Instead, it was seen that the most practical conception of respiration requires a sharp distinction between the influences of oxygen and of carbon dioxide in the control of breathing. Neither oxygen nor oxygen deficiency acts as a stimulus. Instead, oxygen largely determines the sensitivity of the neurorespiratory system to its specific stimulus, which is carbon dioxide. Slight oxygen deficiency increases the sensitivity, so that even the normal amount of carbon dioxide affords an excessive stimulus, and hyperpnea results. On the other hand, extreme deficiency of oxygen diminishes the sensitivity and finally paralyzes the system. And the greater the depression of sensitivity, the stronger the stimulus required to excite respiration to activity. This is not a theoretical explanation, that is still to be developed. It is a practical statement of the unique effectiveness of high concentrations of carbon dioxide, up to 20 or even 30 per cent, in extreme cases of asphyxia neonatorum, while lower percentages are sufficient in all moderate cases.

After the presentation of these conceptions, the more important forms of asphyxia, and their characteristics in relation to resuscitation, may now be considered in some detail.

(To be continued)

## Council on Pharmacy and Chemistry

### NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

#### DEXTROSE (See New and Nonofficial Remedies, 1934, p. 270)

The following dosage form has been accepted:

*Ampoules Dextrose (d Glucose)* 50 Gm 100 cc. Each ampule contains dextrose (d glucose) 50 Gm in distilled water to make 100 cc.

Prepared by the Lakeside Laboratories Inc., Milwaukee. No U. S. patent or trademark.

#### DIPHtheria TOXOID, ALUM PRECIPITATED (REFINED) (See New and Nonofficial Remedies, 1934, p. 393)

United States Standard Products Company, Woodworth, Wis.

*Diphtheria Toxoid Alum Precipitated Refined*—Prepared by treating diphtheria toxin with 0.3 to 0.4 per cent formaldehyde at temperatures of from 35 to 40 C until its toxicity is reduced to the point where five human doses, injected into a guinea pig, produce no symptoms of diphtheria poisoning. The toxoid is treated with a 4 per cent solution of potassium aluminum sulphate, the total amount of which is not to exceed 20 mg per human dose of the finished product. The resulting precipitate is washed with sterile physiologic solution of sodium chloride and resuspended in physiologic solution of sodium chloride to which merthiolate (1:10,000) has been added. The product is tested for antigenic potency according to the method prescribed by the National Institute of Health. Guinea pigs weighing 500 Gm, given one human dose, must produce at the end of six weeks at least two units of diphtheria antitoxin in each cubic centimeter of blood.

Marketed in packages of one 1 cc vial (one immunizing dose) in packages of ten 1 cc vials (ten immunizing doses) and in packages of one 10 cc vial (ten immunizing doses).

### REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT  
PAUL NICHOLAS LEECH, Secretary

#### SQUIBB ADEX TABLETS 10-D NOT ACCEPTABLE FOR N N R (II)

In 1932 the Council published a report on this product declaring it unacceptable because the application of a proprietary name to a cod liver oil concentrate with viosterol is not in the interest of the medical profession or the public (THE JOURNAL, March 19, 1932, p. 982). Subsequently the firm expressed a desire to meet the wishes of the Council in the matter of the name for this product and proposed the name "Squibb A and D EXT Tablets 10-D." The product was then declared to be "a concentrated extract of the vitamins of Cod and Halibut Liver Oils with Viosterol." The firm was informed that the proposed name was not acceptable, since it is essentially a proprietary name differing from "Adex" only in spelling. The firm later proposed the name "Squibb Vitamin A and D Tablets." The Council could not recognize this name, because the product is not pure vitamins A and D, this name does not indicate whether the product is an extract or a concentrate. The firm has been informed, however, that the Council has voted to accept such products under the nonproprietary name "Tablets Vitamins A and D Concentrate" with the understanding that the label state the genesis of vitamins as well as the number of units from each source. Although the most recent available labels for Adex Tablets as well as the firm's proposed label for "A and D EXT Tablets" declare the sources of the vitamins contained, none give the amount taken from each source.

After considerable correspondence, the firm informed the Council that since it would mean considerable loss to change the name "Adex" and to adopt a longer name in conformance with the Council's desire for a more informative designation, it had reluctantly decided to continue the name "Adex." The firm expressed the desire to adhere "in every other respect" to the rules of the Council concerning the marketing of this

product and submitted three advertisements which had been prepared as a part of the fall campaign in promotion of Adex Tablets, asking that the Council consider the acceptability of these advertisements. The Council could not undertake to supervise and endorse advertising for an unacceptable product over which it has no real control. The firm was informed, however, that the Council reserves the right to criticize such advertising on its own initiative.

The Council feels that it is irrational to have a series of special names for cod liver oil concentrate tablets, since the common features of these are more important than the differences. The Council further feels that in the case of Adex Tablets neither the higher dosage content nor the special process of protecting the vitamin content (if, indeed, tablets need such protection) represents such an improvement over available preparations as to justify the use of a coined proprietary name.

Since E. R. Squibb & Sons refused to make the name acceptable the Council reaffirmed its rejection of Squibb Adex Tablets 10 D and authorized publication of the foregoing statement.

## Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING AMENDED RULE

RAYMOND HERTWIG Secretary

### SPECIAL PURPOSE FOODS

"Special Purpose Foods" with usefulness restricted to specific purposes, such as inclusion in diets for obesity or special morbid conditions, will be judged on the basis of their probable usefulness and special adaptability. Food products with very low content of dextrose formers, products with little or no caloric content, and products with features of special adaptability and usefulness for the preparation of special diets, will be accepted provided the package label and advertising meet requirements set forth in the following paragraph and the cost is not wholly out of proportion to the possible usefulness of the products.

The labels and advertising shall prominently display, in easily legible type, the designation "Special Purpose Food," a statement listing all ingredients in the order of decreasing predominance by weight, and the special purpose of the product. These statements, so far as is practical, should be in close proximity to the trade name. In addition, as much of the following information should be given as is significant to permit the intelligent use of the particular product by the consumer: specific properties, vitamin and mineral content, the calories per gram or ounce, and the grams each of carbohydrate, protein and fat per portion.

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

#### CROSSE & BLACKWELL TOMATO JUICE

**Manufacturer**—The Crosse & Blackwell Company, Baltimore

**Description**—Tomato juice, retaining in high degree the natural vitamins. Seasoned with salt.

**Manufacture**—Tomatoes are washed in running water and then by water sprays. The ripest and those free from blemishes are selected for preparing the juice and are trimmed, chopped and preheated to 77° C. in tubes in an atmosphere of steam. The juice is expressed in a steam atmosphere, delivered to tanks where salt is added, passed into the bottom of a filling tank, and at 75° C. filled into cans by gravity. The cans are sealed at once, processed at 100° C. and cooled to 38° C. The juice packed in bottles is homogenized before filling.

The equipment and method of preparation are especially designed to prevent incorporation of air in the juice and to protect efficiently the natural vitamins. Within fifteen minutes after expression of the juice, it is sealed in the containers.

#### Analysis (submitted by manufacturer) —

	per cent
Moisture	94.3
Ash	0.8
Sodium chloride	0.4
Fat (ether extract)	0.1
Protein (N × 6.25)	1.0
Reducing sugars as dextrose before inversion	2.7
Reducing sugars as dextrose after inversion	2.8
Crude fiber	0.2
Carbohydrates other than crude fiber (by difference)	3.2
Acidity as citric acid	0.4

**Calories**—0.2 per gram 6 per ounce

**Vitamins**—Process is efficient to retain vitamins A and C in high degree.

**Claims of Manufacturers**—Especially prepared for table use and as a vitamin C supplementary food for infant feeding.

#### GOLDEN FRUIT BRAND PURE LEMON JUICE

**Manufacturer**—Golden Fruit Products Co., Los Angeles

**Description**—Processed lemon juice, retaining in high degree the natural vitamin content.

**Manufacture**—Ripe washed lemons are sorted by hand to remove any spoiled fruit and are automatically halved and reamed by machine. The juice is centrifugated, run through a block tin coil submerged in hot water (93° C.) and machine bottled in clean, heated dark brown bottles. The bottled juice is submerged in hot water brought to a temperature of 66° C. in from fifteen to twenty minutes, and sealed.

#### Analysis (submitted by manufacturer) —

	per cent
Moisture	91.7
Total solids	8.3
Suspended solids	0.3
Ash	0.4
Fat (ether extract)	0.01
Protein (N × 6.25)	0.4
Reducing sugars as invert sugar	1.9
Sucrose (copper reduction method)	0.0
Crude fiber	0.0
Carbohydrates (by difference)	1.5
Titrate acidity as citric acid	6.0
Iron (Fe)	0.0013
Phosphoric anhydride (P <sub>2</sub> O <sub>5</sub> )	0.038 as P 0.017
Copper (Cu)	1.9 parts per million
Artificial coloring	none
Preservatives	none

**Calories**—0.3 per gram 9 per ounce

**Vitamins**—Chemical analysis for ascorbic acid of sample stored for five months shows retention of 92 per cent of ascorbic acid of the freshly expressed juice indicating that vitamin C is retained in high degree.

**Claims of Manufacturer**—For all uses of lemon juice.

#### CELLU JUICE-PAK APRICOTS

**Distributor**—The Chicago Dietetic Supply House, Inc., Chicago

**Packer**—Hunt Bros. Packing Company, San Francisco

**Description**—Processed, halved and stoned apricots packed in undiluted juice without added sugar.

**Manufacture**—Tree ripened fruit is halved, pitted, washed under water sprays, sorted (all defective fruit removed), graded, washed and placed in cans, to which is added undiluted, filtered juice expressed from off-size apricots. The treatment thereafter is essentially the same as for Cellu Juice-Pak Bartlett Pears (THE JOURNAL, Aug. 4, 1934, page 341).

#### Analysis (submitted by distributor) —

	per cent
Moisture	87.3
Ash	0.7
Fat (ether extract)	0.2
Protein (N × 6.25)	0.4
Reducing sugars as invert sugar	6.8
Sucrose	2.6
Crude fiber	0.5
Carbohydrates other than crude fiber (by difference)	10.9

**Calories**—0.5 per gram 14 per ounce

**Claims of Manufacturer**—Packed in undiluted apricot juice without added sugar.

## THE COMPOSITION OF TISSUE PROTEINS

As the principal component of the solid matter of protoplasm and of much of the intercellular material of tissue is protein, the body must depend to a considerable extent on this nitrogenous material for its growth and maintenance. The proteins of the tissues are synthesized from the assortment of amino acids that accumulate in the cellular and intercellular fluids during the hours immediately following a meal containing protein. These synthetic products appear to be characteristic for each tissue of an animal. For example, hemoglobin, the so-called respiratory protein of the blood, will differ in its amino acid make-up from the protein of the muscle. The mechanism by which each tissue selects particular amino acids in the right proportion to form its own specific nitrogen-containing complexes is unknown, but recent investigations have strikingly supported the remarkable specificity manifested by the mammalian organism in these biochemical processes. Attention has been drawn to the basic amino acids arginine, histidine and lysine, the so-called hexone bases, and the constant proportions of these amino acids, which are obtained by hydrolysis of tissue proteins.

Investigators at Yale University have presented evidence<sup>1</sup> for the hypothesis that "the protoplasm of a specific organism, tissue, cell mass, or certain derivatives thereof, is composed of a labile nitrogenous chemical aggregate, tissue protein, which yields arginine, histidine and lysine in molecular ratios that are approximately fixed and characteristic for that tissue as it exists in various classes of animals." Furthermore, considerable significance attaches to the observation that the ratios of basic amino acids obtained from the total protein of human serum is constant even though the amount of total protein may vary 100 per cent and the value of the ratio of serum albumin to serum

globulin may fluctuate widely. It is suggested that "tissue proteins are built upon an 'anlage' of arginine, histidine and lysine," and stress is placed on the "primary importance of the basic amino acids in the genetic and embryological development of the tissue protein as it exists in protoplasm."

Additional evidence for the constant, specific composition imparted to new tissue proteins formed in the animal body is afforded through experimental efforts to alter the composition of the developing hen's egg by variation in the dietary regimen of the bird. Workers in Ontario<sup>2</sup> have studied the influence of diet on the composition of the proteins of eggs; it was not possible to obtain any clear evidence that the diet of the hen had an effect on the percentages of the various amino acids studied. Similar extensive investigations have been recently described by Calvery and Titus<sup>3</sup>. These authors were unable to find any marked differences in the composition of the same proteins prepared from the eggs produced by pullets raised and kept on diets having entirely different sources of nitrogenous food-stuffs. This ability of the organism to put together ten or fifteen or even more different individual amino acids to produce a protein characteristic of a particular tissue must involve specific synthetic processes the mechanism of which challenges the most vivid of investigative imaginations.

## CONTRACEPTION AND BIRTH CONTROL

In a test of more than 100 so-called contraceptives undertaken by the Birth Control Clinic Research Bureau, New York, forty-five were discovered to be unreliable. Today the marketing of devices, drugs and techniques for the prevention of conception is in the realm of big business. Indeed, the marketing of books on the subject has also come to be an exceedingly profitable venture.

In a recent consideration of birth control as a business, Elizabeth H. Garrett<sup>1</sup> credits the tremendous recent expansion to a court decision which affirmed that sales of materials for birth control were legal unless the seller was in complicity with drugstores to resell illegally. The court also said "The intention to prevent a proper medical use of drugs or other articles merely because they are capable of illegal uses is not lightly to be ascribed to Congress." The decision was handed down in 1930. Immediately the country began to be flooded with all sorts of material sent in circulars through the mails to doctors, druggists and the public. Advertisements for feminine hygiene began to appear in the most dignified periodicals. More recently the term "marriage hygiene" has been developed to point

the use more specifically. Today there are hundreds of jellies, suppositories, rubber devices and systems sold for such purposes throughout the country, as well as many antiseptics that have about the same efficiency as water. A survey in the western part of Florida in 1932 is said to have revealed the information that preventives were sold in 376 places besides drugstores, including gas stations, garages, restaurants, soda fountains, barber shops, pool rooms, cigar stands, news stands, shoe shining parlors and grocery stores. The president of one concern manufacturing a rubber device stated that its business marketed 12,000 gross a month. At the recent annual session of the American Medical Association, held in Cleveland, a resolution was introduced requesting the Board of Trustees to set up some machinery for the scientific study of the various medicaments and devices available, the resolution was tabled by the House of Delegates.

A ray of light in the situation is the so-called Ogino-Knaus biologic law of nature, which deals with the establishment of the so-called safe period. The views of Ogino<sup>2</sup> have recently been made available in a translation of his Japanese book on the subject. Knaus's<sup>3</sup> research has just been published in book form in German with a menstruation calendar neatly inserted in the inside cover, and the volume by Latz<sup>4</sup> dealing with this method has sold well nigh unto 100,000 copies. Furthermore, all sorts of slide rules, calendars and record sheets are being offered to the public by interested manufacturers as a means of promoting this technic for the prevention of conception.

The views of Ogino were advanced in 1924 and he received the prize of the Japanese Gynecologic Society for his work in 1925. Knaus credits his investigations to a stimulus given by the work of Prof. A. J. Clark, published in London in 1924, on the physiology and pharmacology of the uterine musculature, and to the studies that were continued under the late Prof. W. E. Dixon in Cambridge from April 1925 onward. Knaus arrived independently at the establishment of the "safe period." He points out that Ogino's work was not known in Europe when in 1929 he published his own statements on the subject. The idea of a "safe period" goes back, of course, to the Mosaic laws, which through their establishment of ritual cleansing and other processes for women definitely indicated the period during which the woman was most likely to conceive. In fact, Genesis, chapter 1, verse 28, is an order to utilize the fertile period and multiply as the sands of the sea.

Briefly, it is claimed that the five days from the twelfth to the sixteenth day before a subsequent menstruation is the period of ovulation and that this period

is the period during which fertilization is most likely. Within twenty-four hours after ovulation is completed the safe period probably begins. It is fairly well established that the fertilizing ability of the spermatozoa is within a three day period. In the vast majority of cases the human conception period is therefore within the eight days from the twelfth to the nineteenth day before a subsequent menstruation. Means have been developed for careful recording of the menses for menstrual cycles of various durations from twenty-three to thirty days in order to set forth clearly the sterile and safe periods.

Because of the biologic character of this means of prevention of conception it has not apparently been opposed by church, state or other organizations in the manner in which more artificial methods have been opposed. Indeed, it has even had endorsement from some religious groups. Enough evidence has already been established to indicate that a strict observance of the method is insurance of sterility even beyond that associated with the employment of most of the contraceptive apparatus and medicaments. In the vast majority of cases it will, of course, be desirable for the family physician to instruct his patients as to the basis of this method of birth control and as to proper employment. Latz states that he received only one complaint against the system for every 4,000 books sold and in instances in which investigation was possible it was discovered that the employment of the method had not been intelligent. Smulders in Holland has made available records of many thousands of cases of successful practice of this method of birth control.

In view of the availability of this technic, depending on a knowledge of biology, and in view of the tremendous expansion of the business aspects of birth control already mentioned, it would seem to be exceedingly important for some authoritative body to undertake a suitable study of the materials and methods of promotion now being exploited in this country. Whether or not legislation eventually ensues that will throw open the mails and the press to suitable discussion of the subject, the situation now prevailing is warrant for some type of action leading to scientific control.

#### SYNERGISTIC ETIOLOGY OF POLIOMYELITIS

If normal rabbits are injected intravenously with sublethal doses of cholera vibrios, the micro-organisms usually "localize" in the intestinal mucosa, the blood and most of the extra-enteric tissues becoming free from the injected bacilli. The resulting enteric carriers of the comma bacillus usually do not show recognizable cholera symptoms. If, however, these carriers are injected intravenously with alien bacterial products, such as *Bacillus coli* or *Bacillus proteus* filtrate, a violent local hemorrhagic or desquamating enteritis results,

<sup>2</sup> Ogino Kyusaku. Conception Period of Women. Harrisburg: Pa. Medical Arts Publishing Company.

<sup>4</sup> Latz L. J. The Rhythm of Sterility and Fertility in Women. Chicago: Latz Foundation.

often accompanied by severe or even fatal systemic toxemia. This nonspecific or synergistic local and constitutional reaction was first described in 1924 by Sanarelli,<sup>1</sup> who characterized it as an "epithelial shock" or "epithelaxie."

"Sanarelli anaphylaxis" is not apparently confined to the enteric tissues, however. Schwartzman,<sup>2</sup> Sickles,<sup>3</sup> and Freund and Smith,<sup>4</sup> for example, found that a wide range of bacterial products injected intracutaneously into rabbits will render the injected skin areas nonspecifically hypersensitive to heterophile factors. Violent hemorrhagic reactions may occur in the prepared skin areas on the intravenous injection of such substances as agar, gelatin, india ink or soluble starch, or with a wide range of normally nontoxic bacterial filtrates. Gratia and Linz<sup>5</sup> have described a similar nonspecific allergic syndrome in locally infected subcutaneous tissues. Bordet<sup>6</sup> found equally pronounced local Sanarelli reactions in experimentally inoculated lymph nodes and other retroperitoneal tissues. He describes a violent nonspecific and often fatal synergistic shock in tuberculous peritonitis, for example, on the intravenous injection of *Bacillus coli* filtrate. This nonspecific sensitivity of tuberculous animals has, of course, long been known to immunologists, having been described as early as 1891 by Roemer.

While the phenomenon of "nonspecific allergy"<sup>7</sup> is of interest in its bearing on theories of specific antibody production, it is also suggestive with regard to many practical problems of clinical medicine. Hanger<sup>7</sup> has described a synergistic syndrome in certain infections of the upper respiratory tract in rabbits. He found, for example, that many upper respiratory carriers of *Bacterium lepi-septicum* are without demonstrable symptoms. Explosive allergic reactions occur in the nasal mucosa, however, on the intravenous injection of heterophile bacterial filtrates, giving symptoms commonly designated as "snuffles." This strongly suggests that in many cases "snuffles" is of synergistic or duplex etiology, owing to a local and perhaps symptom-free infection of the nasal mucosa "accentuated" by mildly toxic bacterial products absorbed from the gastrointestinal tract.

Hanger's observation is pertinent, since Toomey<sup>8</sup> has recently reported experimental evidence suggesting a somewhat similar synergistic or duplex etiology for polyomyelitis.

## Current Comment

### EPIDEMIC ENCEPHALITIS

The symposium on epidemic encephalitis appearing in THE JOURNAL this week (pp 726-735) and to be concluded in the next issue is an exceptional account of an unusual type of epidemic encephalitis. The St. Louis epidemic of 1933 in many respects was unlike the infectious encephalitis that has prevailed in other sections of the United States in recent years and which had come to be known as the von Economo type. In fact, the exact nature of this outbreak was not recognized until after the opportunity had presented itself to perform the first necropsy. The closest precedent for the St. Louis outbreak was an epidemic of thirty-eight cases that occurred in the summer of 1932 in Paris, Ill. There was much similarity also to the type of disease in the great epidemic that occurred in Japan in 1924. The St. Louis epidemic has the distinction, Neal says, of being the only outbreak of epidemic encephalitis in which the etiologic agent has been definitely established. This is a newly isolated filtrable virus that was pathogenic for mice and less so for rhesus monkeys. It was thought that the virus was the same type as the Japanese type B, but at least serologic differences were demonstrated when convalescent serum was obtained from Japan. Strains of the St. Louis virus were isolated in two different laboratories. The research and investigation of the St. Louis epidemic were extremely well done by the St. Louis medical schools, local physicians and health authorities, experts from the United States Public Health Service, the U. S. Army, and other organizations. It represented a modern, well coordinated, cooperative attack on the problems concerned. Epidemics of encephalitis usually start in the summer or in the autumn. Some public health departments have announced that the disease is at present on the increase in their localities. Physicians should become familiar with the facts available on this unusual type of encephalitis, as presented in this symposium.

### THE INCIDENCE OF TRICHINOSIS

Despite the wide dissemination of popular dietary knowledge, frequent examples continue to occur of cases of diseases which, although not of primary importance from the point of view of a major health problem, are completely preventable. The incidence of trichinosis affords an interesting illustration. Sporadic cases, as well as small epidemics, of trichinosis occur throughout the world with disconcerting frequency. German reports show that in 1923 and 1924 there were 150 cases with one death at Karlsruhe and, in 1926, 100 cases and six deaths in Klingenthal.<sup>1</sup> In Spain in 1915 there were 145 cases with seventeen deaths.<sup>1</sup> In the United States, recent cases are reported in the literature only because of some special aspect. A group of eleven cases with recovery was recorded in New York

State in 1932.<sup>2</sup> In the same year<sup>3</sup> there was an account from California of an outbreak of human trichinosis with one death following the ingestion of trichinous bear meat in the form of "jerky." In this instance the brown bear was the cause of infection, whereas customarily pork is the offending meat. Two recent reports dealing with trichinosis serve to emphasize the fact that an unusually large number of cases has come to light during the past few years. An outbreak arising from the ingestion of home-made sausage and involving forty-three persons was reported last year in New Jersey.<sup>4</sup> An interesting account by the United States Public Health Service<sup>1</sup> presents epidemiologic data on 166 cases of trichinosis reported to the New York City Department of Health for the years 1929-1933 inclusive. It is of considerable significance that the ingested pork products have frequently been approved by the United States Department of Agriculture. This serves to emphasize that the usual government inspection of fresh pork and pork products is by no means an adequate criterion of freedom of the pork from trichinae, a fact repeatedly emphasized by the United States Department of Agriculture.<sup>5</sup> In view of the fact that complete cooking will absolutely prevent the disease, every one should be educated to the importance of eating only thoroughly cooked pork and pork products.

## Medical Economics

### THE WAYNE COUNTY MEDICAL SOCIETY, DETROIT, PLAN

Complete medical service without the use of the insurance principle is being offered and given to wage earners of Detroit through a plan developed and put into operation by the Wayne County Medical Society, Detroit. A demonstration set-up is bringing medical care to hundreds of employed persons of small means, people who do not want paternalism or charity but merely credit.

The Wayne County Medical Society plan, originated by Dr. Ralph H. Pino of Detroit, was very carefully scrutinized by the Wayne County Medical Society for more than eighteen months before it was approved by the society's council, Feb. 16, 1934. The board of trustees then appropriated sufficient money to inaugurate and maintain a bureau to put the plan into operation. It is owned and operated exclusively by the Wayne County Medical Society and the administrative office is located in the society's building at 4421 Woodward Avenue, Detroit.

Eliminating the salaried class, which is able to handle its own medical problems, the remaining three classes of people in Detroit can procure medical service through the agency of the Wayne County Medical Society.

1 The unemployed on welfare rolls receive home and office medical service by the family physician, dentist, and so on, through the Medical-Dental Bureau, operated by the Wayne County Medical Society in its building. The cost of this agency is met by the FERA.

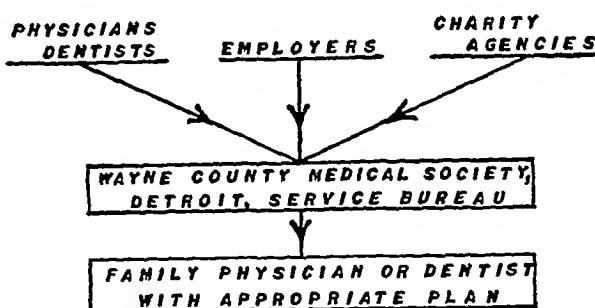

2 The unemployed not on welfare rolls are cared for in Detroit through the Medical Relief Committee on the Wayne

County Medical Society. The family physician or volunteers who serve these people with home and office care at no fees, or at small fees assist the patient to maintain his self respect.

3 Employed persons earning small wages or salaries are cared for in Detroit by the bureau developed from the Wayne County Medical Society plan.

This plan offers complete medical care, comprising the services of physicians, hospitals, dentists, nurses and pharmacists, at a fee that can be paid by easy time payments within a year's time or less.

## SOURCES OF REFERRED PATIENTS

### NO MEDICAL DOLE FOR EMPLOYED WORKERS

The purpose of the Wayne County Medical Society Bureau is to assure employed people of modest income that they can go to the physician of their choice and receive necessary medical service when they need it. Furthermore, the bureau works out a plan for them whereby the account can be paid from week to week.

Those people who for financial reasons are neglecting their health are encouraged to get in touch with the bureau. Because they have no cash reserve is no reason that medical service must come to them through the agency of free dispensaries and tax supported hospitals and clinics.

### PROFESSIONS UNITE TO GIVE SERVICE

The bureau is a demonstration in cooperation. Five professional groups (physicians, hospitals, dentists, nurses and pharmacists) are working together to provide high grade services to the employed worker of small means. Industrial concerns, realizing that healthy workers are more efficient and desirable, cooperate by (1) telling employees to see their family doctors, (2) verifying employment wages and giving credit information to the Bureau on request, (3) assisting in the collection of a fair fee, based on the employee's ability to pay.

Some idea of the immense amount of work necessary to make this plan a success may be gained from the following data. There are over 7,000 units of medical service (physicians, dentists, nurses, pharmacists and hospitals) in Detroit and Wayne County. There are over 2,400 industrial units or employers (factories, shops, and the like) in the same area. The cooperation of all these is necessary to the complete success of this demonstration. The staff at the Wayne County Medical Society is working constantly to establish these contacts and to create the organization necessary to care for all patients who apply at the bureau for aid. It will require more than a year of intensive effort to complete arrangements so that every employer and worker in Detroit and Wayne County will know of this opportunity for service offered by the Wayne County Medical Society.

### TEN POINTS

The essential features of the medical service plan may be briefly summarized as follows:

1 The Wayne County Medical Society headquarters become a coordinating center (with a social service set-up) for those cases which require assistance in obtaining and paying for

<sup>2</sup> Reifstein E. C. Allen E. G. and Allen G. S. Trichinosis. Am. J. M. Sc. 183: 668 (May) 1932.

<sup>3</sup> Walker A. T. Trichinosis. J. A. M. A. 98: 2051 (June 11) 1932.

<sup>4</sup> Kilduffe R. A. Barbash Samuel and Merendino A. G. Am. J. M. Sc. 186: 794 (Dec.) 1933.

<sup>5</sup> Swartz B. U. S. Dept. Agric. Bureau of Animal Industry. Leaflet 34. May 1929.

complete medical service, including hospitalization and medical, dental, nursing and pharmaceutical service

2 The members of the professions become the active staff caring for patients. All forms of medical care, consultation, x-ray and laboratory procedures are to be performed in the office or laboratory of the physician or at the hospital where he takes his patients

3 This plan includes hospitalization—all the major hospitals of Detroit are cooperating, except one

4 Arrangements have been and are being made with industrial concerns to make this service known to their employees. The factories and shops are cooperating in giving information and in the collection of accounts. To date the plan has received an enthusiastic welcome by each employer approached

5 All cases in which the benefits of the coordinating plan are desired will be registered at the Wayne County Medical Society headquarters and referred to the family doctor, if the patient has one. If the patient has no physician, he is asked to select one. The patient will be given an identification card to be presented by him to the physician selected

6 If several physicians and a hospital cooperate in the care of a case, the bills for fees will be combined into one bill and terms will be arranged according to the patient's ability to pay. The physician and the hospital set the fees—not the bureau. Payments received by the central bureau will be distributed to each cooperating physician, hospital, dentist or nurse

7 This plan preserves the recognized patient-physician relationship. It does not affect compensation cases. The patient always has a free choice of physician or dentist and the physician has free choice of hospitals, specialists and laboratories exactly as carried on in private practice

8 The most important feature of this plan is that it places complete medical and hospital services within the reach of every worthy patient and provides an easy payment plan for the settlement of medical bills

9 The plan should increase the health and happiness of Detroit and Wayne County citizens, as it provides a method whereby people can procure needed medical services. It should remove a large proportion of the financial reasons for delaying medical service. The consolidation of medical and hospital bills, with the arrangement of definite terms at the time the service is rendered should result, with the cooperation of the employer and all concerned, in an increased ratio of collections

10 Physicians send their bills computed at their usual fees for these patients to bureau headquarters giving certain details of their charges. The physician does not make collection of these charges—the central bureau makes arrangements for collections and has the cooperation of the employer. To defray the cost of operating the bureau, 10 per cent of sums actually collected is retained by the bureau

#### THE ADVISORY GROUP

The bureau is under the direct financial and executive control of the board of trustees of the Wayne County Medical Society. An advisory committee, called the Board of Arbitration, aids the board of trustees with recommendations regarding details of operation, handles disputes, and assists the smooth performance of the bureau. Representatives of the various cooperating professional groups are seated on the Board of Arbitration. The bureau is under the coordinating supervision of the executive secretary of the Wayne County Medical Society

The Wayne County Medical Society Bureau has grown so rapidly that statistics are obsolete almost before they can be published. The plan has received a hearty welcome from every industrialist to whom it has been explained. The total number of employees of the industries now cooperating with the bureau is approximately 229,980. Industrial concerns have various methods of cooperating with the central bureau (such as by pay-roll deductions and employee loans), but they all agree on one point: they are willing to extend every courtesy to the medical organizations if they can cooperate with one center but it is impossible for them to deal with over 7,000 individual units who serve the public. Their reason is obvious. One central bureau in the medical society would entail only one

deduction from pay-rolls per month to cover the medical welfare of their employees, the bookkeeping is thus greatly simplified. If, however, the industrial concern attempted similar cooperation with thousands of individual physicians, dentists and hospitals, it would require a tremendous amount of detailed and expensive bookkeeping. Centralized bookkeeping and collections are vital in obtaining the cooperation of large employers of labor. They hesitate to promise cooperation except with one center

#### CHARITY CHISELERS DISCOURAGED

During recent months, welfare agencies in Detroit (like other large centers) have been flooded with requests for free medical care. When approached by the Wayne County Medical Society and asked to cooperate with its bureau, the officials in charge were glad to conserve public funds by referring all patients able to pay something for medical service to the bureau. These patients are always returned to their family practitioner with a plan of deferred payments. The majority of these patients sought charity because they did not have sufficient cash in reserve to meet the full fees incident to a medical emergency. Their prime need was credit—not free medical care. Already many families have been spared the humiliation of charity by the alert cooperation of the investigators in Detroit's public charity institutions. The bureau will continue its contact with free and part pay dispensaries and clinics with a view to returning as many cases as possible to the private practitioner of medicine in order to strengthen the traditional physician-patient relationship

#### A GOING CONCERN

Since Feb 16 1934, the bureau has been of service to 937 patients (as of Aug 18, 1934) and has not refused service to any deserving applicant. In every case service was rendered immediately without red tape. The universal gratitude of patients has been encouraging

Patients who erroneously thought they could not pay for medical service have contributed to the bureau in small weekly instalments of one, two and three dollars (occasionally a little more) the surprising total of \$13,140.13 (as of Aug 18, 1934). The rapid acceleration of total payments as the number of cases increases is illustrated by the fact that while \$3,563.82 was collected during the month of July a total of \$3,417.81 was paid in during the first sixteen working days of August

#### THE BUREAU SOLVES PROBLEM CASES

The bureau has not advertised its services because a large volume of cases could not be handled by the present small administrative staff of the bureau. Experimental publicity has been released to the employees of one large manufacturing concern by a write up in the employees' monthly magazine. The following quotation from this publication illustrates the manner in which the bureau intends to route sick employees or members of their families to their private practitioner, and if financial problems cannot be solved by him, to work out a plan for the benefit of the patient and the doctor

#### WHAT TO DO WHEN SICK

In case of illness in your family call your family doctor. Let him examine the patient and make his diagnosis. If you are unable to pay cash for the necessary treatment ask your doctor to refer you for help to the Wayne County Medical Society Service Bureau, Wayne County Medical Society Building, Detroit. The Bureau will work out an easy payment plan so you can get rid of that pain or sickness today. There are no dues, service charges or interest for you to pay

The bureau believes that this type of publicity will increase the number of patients seeking medical care in physicians' offices and will lessen the dispensary load and taxpayers' burden

During the last few years the medical profession has been subjected to unjust and severe criticism, and many opportunists have taken advantage of the smoke screen to formulate schemes (usually socialistic) having bigger and better medical service to the middle class patient as excuse for their meddling. Through its bureau the Wayne County Medical Society of Detroit is seeking to demonstrate that medical care can be supplied those who need it—not through insurance, not through government or political agencies, but through the sane and unselfish work of the individual doctor of medicine coordinated by his county medical society

## Association News

### MEDICAL BROADCASTS Columbia Broadcasting System

The American Medical Association broadcasts on a Western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45, Central daylight saving time. The next three broadcasts will be as follows:

- Sept. 13 Common Eye Troubles, William C. Benedict, M.D., representing the meeting of the American Academy of Ophthalmology and Otolaryngology in Chicago
- Sept. 20 Infantile Paralysis, W. W. Bauer, M.D.
- Sept. 27 Swimming Pool Sanitation, J. F. Hammond, M.D.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

### ALABAMA

**Typhoid in Decatur**—Typhoid was reported in Decatur, recently, when fourteen people who drank water from a contaminated well developed the disease. The well water was used for drinking purposes after the water company had discontinued its service for nonpayment of bills; it was stated. A survey was made by the state board of health and the well was closed. Service was resumed by the water company.

**Mosquito Eradication**—Fourteen counties in the state had announced their agreement to participate in a campaign to eradicate mosquitoes, newspapers reported, August 7. The campaign was to be undertaken as a precautionary measure against dengue fever, since several cases had been reported in other southern states. 800 cases of the disease having been reported in Miami, Fla., alone.

**Dr. Baker Appointed to National Board**—Dr. James N. Baker, Montgomery, state health officer, has been appointed a member of the National Board of Medical Examiners for a term of six years, to succeed Dr. Waller S. Leathers, dean of Vanderbilt University School of Medicine. Dr. Baker is a graduate of the University of Virginia Department of Medicine and has been state health officer since 1930, prior to his appointment he had been a practitioner in Montgomery for thirty years.

### COLORADO

**State Medical Meeting at Colorado Springs, September 19-22**—The sixty-fourth annual session of the Colorado State Medical Society will be held at Colorado Springs, September 19-22, with headquarters at the Antlers Hotel. Out-of-state speakers will include, according to the preliminary program, Drs. Rudolph H. Kampmeier, New Orleans, "Aneurysm of the Thoracic Aorta," Joseph Brennemann, Chicago, "Acute Abdominal Conditions in Children," and Walter L. Biering, Des Moines, Iowa, President, American Medical Association "Heart Disease and the General Practitioner." Included among other speakers are the following physicians:

- William H. Mast, Gunnison, Acute Disorders Simulating Surgical Conditions of the Abdomen
- Herman J. Laff, Denver, Diagnosis of Mastoiditis
- Clinton E. Harris, Woodmen, The Common Cold
- Charles W. Streamer, Pueblo, Traumatic Surgery in Automobile Accidents
- Hermann B. Stein, Denver, The Apple Diet in Treating Diarrheas of Infants and Children
- Herman C. Graves, Jr., Canon City, Early Diagnosis of Peripheral Circulatory Diseases
- Sanford M. Withers, Denver, Cancer of the Breast
- Edward N. Chapman, Colorado Springs, A Major Public Health Problem in Colorado
- Harry Guss, Denver, Changing Concepts in Nephritis
- Edward Jack, on Denver, The Dangers of Proprietary Drugs
- Ralph W. Danielson, Denver, Role of the Ophthalmoscope in General Practice
- George B. Kent, Denver, Surgical Management of Malignant Lesions of the Colon and Rectum

A fracture seminar will be held Thursday morning, with the following participants: Drs. Hamilton I. Barnard and Atha Thomas, both of Denver; Fred H. Hartshorn, Fort Collins.

Harold R. McKeen and Robert G. Packard, Denver. A symposium on obstetrics will be conducted Friday afternoon by Drs. Gerrit Heusinkveld, John R. Evans, Gunnar Jelstrup, Lyman W. Mason, Edward L. Harvey, Harold J. Von Dctten and James B. Walton, all of Denver. Saturday afternoon will be devoted to a seminar on the endocrines by Drs. Constantine F. Keniper, George M. Z. Williams and Thaddeus P. Sears, Hugh Kingery, Ph.D., and Bernard B. Longwell, Ph.D., all of Denver. Clinical sessions are being added to the program of the state society this year. The annual golf tournament will be held Friday afternoon, September 21.

### CONNECTICUT

**Dr. Maher Honored**—The infirmary building of the new Seaside Sanatorium for children at Waterford has been named in honor of Dr. Stephen J. Maher for twenty years chairman of the state tuberculosis commission. The new sanatorium, erected at a cost of \$500,000, will care for patients with bone and glandular tuberculosis and replace the old building at Crescent Beach. In 1932 Dr. Maher was awarded the Laetare Medal by Notre Dame University, South Bend, Ind.

### GEORGIA

**Extension Course**—Members of the faculty of the University of Georgia School of Medicine, Augusta, presented a series of lectures in Sandersville, August 6-10. The course was one of a series being sponsored by Emory University and University of Georgia under the supervision of the state board of health.

- August 6, Dr. Virgil P. W. Sydenstricker, Treatment of the Anemias
- Dr. George A. Traylor, Compression Fractures of the Vertebrae
- August 7, Dr. George L. Kelly, Functional Dysmenorrhea, the Aschheim-Zondek Test
- Dr. Ferdinand C. Lee, Common Endocrine Disorders
- August 8, Dr. John W. Brittingham, Syphilis of the Central Nervous System
- Dr. Guy T. Bernard, Carcinoma of the Uterus
- August 9, Dr. Ralph H. Chaney, Surgical Treatment of Pulmonary Tuberculosis
- Dr. Robert C. McGhee, Congenital Syphilis
- August 10, Dr. Henry M. Michel, Diseases of the Hip Joint
- Dr. Thomas B. Phinzy, Preventive Pediatrics

**Society News**—Dr. Charles C. Harrold, Macon, was elected president of the Chattahoochee Valley Medical and Surgical Association at its annual meeting in Albany, July 12, succeeding Dr. Agnew H. Hilsman, Albany. Dr. Marion T. Davidson, Birmingham, Ala., and Dr. Mathew Jay Flipse, Miami, were elected vice presidents, and Dr. William J. Love, Opelika, Ala., secretary. The association will hold its 1935 meeting in Albany. —Dr. James E. Paulin, Atlanta, addressed the Lowndes County Medical Association, recently, on arthritis.

### ILLINOIS

**Richland County Leads in Maternal Mortality**—Figures obtained in a study of maternal mortality in Illinois during the last five years by the state department of health reveal that Richland County leads in maternal deaths with a rate of 16.1 per thousand births. This rate is three times as high as that for the state as a whole (5.6). Twenty-four maternal deaths occurred in the county among 1,488 births. Three counties, Bond, Menard and Putnam, reported no maternal deaths in connection with 2,146 births during the five years. Counties reporting rates of 10 or more during this period include Lee, 13.8, Pulaski, 13.6, Alexander, 13.5, Morgan, 11.8, Effingham, 10.5, Scott, 10.4, Perry, 10.1, Saline, 10.1, and Logan, 10.

### Chicago

**Professorship of Nursing Education Created**—With the appointment of Miss Nellie X. Hawkinson as professor of nursing education, a program of nursing education has been begun at the University of Chicago. The committee of nursing education appointed by President Hutchins last winter after a tentative plan for the organization of the courses had been approved will be responsible for the formulation and adoption of the sequences of studies leading to degrees. Sequences for teachers of nursing, supervisors and administrative officers in schools of nursing are being planned as the first step. The degree will be cleared for the present through the division of biological sciences, although the courses included will be offered in education, home economics, psychology and other departments as well as in the science departments.

### IOWA

**Personal**—Mr. C. W. Kammeier was recently appointed executive secretary of the Iowa Tuberculosis Association, succeeding Mr. T. J. Edmonds, resigned. —Dr. Clyde A. Boice, Washington, was reelected president of the state board of health at its annual meeting in Des Moines, July 10.

**Survey of Births**—A report has recently been published on a study covering 129,539 births in Iowa, with special reference to the method of delivery and the stillbirth rate, for the years 1930, 1931 and 1932. There were 3,820 stillbirths among this total, an incidence of 2.94 per cent. Iowa is essentially a rural state and has only twenty-one cities with more than 10,000 population. Births in these urban centers numbered 43,444, while in the rural communities 86,095 births were recorded. For the state as a whole there were 41,418 births in hospitals, giving a percentage of 32. In urban communities 61.9 per cent of all births occurred in hospitals, while in the rural districts the percentage was only 16.9. Of the 129,539 births, the type of delivery was specified in 91,738 cases, in 10,818 operations were performed, a gross operative incidence of 11.8 per cent. Of the various types of deliveries, all varieties of forceps deliveries totaled 6,474, version and extraction, 1,236, cesarean section, 955, breech extraction, 711, craniotomy, 4, while types not specified totaled 1,438. The operative incidence among primiparas (23.1 per cent) was almost four times as great as in multiparas (6.5). The stillbirth rate among primiparas was appreciably higher (3 per cent) than among multiparas (2.4 per cent). The incidence of operative delivery among 89,270 live births was 11.2 per cent, while among 2,468 stillbirths it was 35.1 per cent. In the 37,808 births in which the type of delivery was not stated, the stillbirths numbered 1,352, a rate of 3.6 per cent, while among the 91,738 with delivery data available for analysis there were 2,468 stillbirths, an incidence of 2.7 per cent.

### LOUISIANA

**Society News**—Dr Basil C. MacLern discussed group hospitalization before the Orleans Parish Medical Society in New Orleans, July 9. Speakers before the Second District Medical Society at Destrehan, recently, included Drs Urban Maes and James D. Rives, New Orleans, on "Early Diagnosis of Carcinoma of the Stomach," and "Extra-Gastric Dyspepsias," respectively. The Vernon Parish Medical Society was revived at a meeting, June 30, at which Drs. James F. Smith, Leesville, was elected president, William T. Franklin, Anacoco, vice president, and Daniel O. Willis, Leesville, secretary.

### MARYLAND

**Epidemic of Influenza**—Influenza is spreading over western Maryland, according to the *New York Times*, August 21, at which time the outbreak involved nearly 1,000 cases. Cases have been reported at Hancock, Hagerstown, Rockville, Maugansville and Berkeley Springs, W. Va. The attack is sudden, lasting about five days, and is accompanied with chills, pains in the chest and abdomen, and general weakness.

**Diphtheria Prevention Campaign**—The fourth annual diphtheria prevention campaign will begin in Baltimore, October 1, under the supervision of Dr. Adolph Weinzirl, director, department of communicable diseases. Between now and the opening of the campaign, parents and guardians of young children are advised to secure from their family physicians the toxoid preventive treatment for their children, as soon as possible after they reach the age of 6 months.

### MICHIGAN

**Society News**—The Berrien-Cass County Medical Association met jointly with the Berrien County Bar Association at Berrien Hills Country Club, July 18, a memorial service for the late Dr. Charles N. Sowers, Benton Harbor, was a feature of the program. The Oakland County Medical Society was entertained by the Genesee County Medical Society in Flint, June 20, in the morning, clinics and demonstrations were held at the Hurley Hospital, the afternoon was spent at the Flint Country Club.

### MISSISSIPPI

**Society News**—The Central Medical Society devoted its meeting, July 3, to case reports, participants in the program were Drs. John K. Bullock, Roland W. Hall, Walter F. Henderson, Isaac C. Huggins and Julius Crisler, Jackson. A symposium on the toxemias of pregnancy constituted the program of the Issaquena-Sharkey-Warren Counties Medical Society at Vicksburg, August 14. Dr. Edward C. Mitchell, Memphis, Tenn., among others addressed the Northeast Mississippi Thirteen Counties Medical Society at Greenwood Springs, recently, other speakers included Drs. Hyder F. Brewster, New Orleans, on "Gonococcal Conjunctivitis," Stanley A. Hill, Corinth, "Useful Methods of Treating Fracture of the Femur," and Henry J. Kellum, Tupelo, on "Glaucoma." The North Mississippi Medical Society was addressed at War-

ren Lake near Waterford, June 27, by Drs. J. H. Eugene Rosamond, Memphis, on "Diarrheas of Infancy and Childhood," Dudley R. Moore, Byhalia, "Uterine Displacement," and Raphael E. Semmes, Memphis, "Management of Head Injuries."—Dr. Frank C. Shute, Jr., New Orleans, among others, discussed "Perforated Appendix" before the South Mississippi Medical Society in Hattiesburg, June 14. Speakers before the medical society of Lincoln, Copiah, Lawrence and Walthall counties recently included Drs. William L. Little, Wesson, on scarlet fever, and Thomas F. Conn, Monticello, malaria and its treatment.

### MISSOURI

**Personal**—Dr. James H. Ready has been named head of the medical department of the General American Life Insurance Company, St. Louis, succeeding Dr. James E. Bee, resigned. Dr. Ready will be replaced in his position as assistant medical director by Dr. Lloyd C. Miller, who has been chief medical examiner.

**Society News**—At a meeting of the Cass County Medical Society in Archie, June 14, Drs. Robert M. Miller, Belton, read a paper on "Angina Pectoris" and Vincent T. Williams and John R. Callan, Kansas City, discussed "Pathology of Angina Pectoris and Other Cardiac Lesions."—Dr. Jesse E. Douglass, Webb City, addressed the South Central Counties Medical Society at Thayer, June 28, on "Prevention of Tuberculosis."

**State Tuberculosis Division Approved**—The creation of a tuberculosis control division in the state department of health has been approved by a committee representing the Missouri Tuberculosis Association, the state department of health, the state eleemosynary board and the Missouri Tuberculosis Association. The plan would provide for a full time director in the health department and trained workers to handle the rehabilitation and follow-up work on every case discharged from the various state sanatoriums, according to the state medical journal.

### NEW MEXICO

**Study of Accidental Deaths**—A study of accidental deaths in New Mexico in the last five years shows that deaths from automobile and motorcycle accidents led all other causes by a wide margin, with 542 fatalities. Excessive heat caused five in five years. Other causes were falls and crushing, 190, burns, 172, firearms, 120, drowning, 117, poisons, 100, mines and quarries, 92, railroad, 78, lightning and electric current, 42, excessive cold, 40, air transportation, 24. In 1933, 102 persons met death in automobile or motorcycle accidents.

### NEW YORK

**Death from Beriberi**—The first death from beriberi in the state in fifteen years occurred recently in Buffalo, the state department of health reports. The previous one occurred in New York City in 1919. There have been four deaths from the disease in northern New York in the past twenty years.

**A Boasting Young Russian Jailed**—A young man who was attempting to practice medicine without medical education or license was placed in the Sullivan County jail in August for thirty days on one count and ordered to pay a fine of \$500 on another, with a suspended jail sentence of a year. In conversation with the town constable "Dr." Morris Levine, a guest at the Pine Grove Hotel Monticello, boasted of his extensive practice to such a degree that the constable became suspicious, in view of the youth of the "doctor." The constable then consulted an official of the Sullivan County Medical Society, who found that Levine had given medical treatments to several guests of the hotel. He was arrested on the complaint of one of these, pleaded not guilty before a magistrate and was about to be released on \$500 bail when he was again arrested on a warrant sworn out by another guest. Bail was then set at \$2,000, which Levine was unable to raise. An inspector from the state board of medical examiners assisted with the case. Levine said he was 28 years old, a native of Russia and had lived in the United States since 1928. He said that he had lived for a time in Springfield, Mass., and admitted that he had never studied medicine.

### New York City

**Death from Rabies**—A 7 year old boy died of rabies, August 7, after having been bitten by a rabid dog, July 11. The boy received a lacerated wound on the right eyelid, cheek and chin. Antirabic treatment was started, July 12, and fifteen injections had been given when on August 5 the child developed paralysis, convulsions and difficulty in swallowing. Postmortem examination revealed Negri bodies in the brain.

**Friday Afternoon Lectures**—The fall series of Friday Afternoon Lectures sponsored by the Medical Society of the County of Kings at its Brooklyn headquarters will begin, September 28, with the following speakers for the first month

Dr Edwin H. Fiske, Electrosurgery  
Dr Mervin C. Myerson, subject to be announced  
Dr Bernard Benjamin, Anemia of Infancy and Childhood  
Dr Thomas M. Brennan, Intestinal Obstruction

#### NORTH DAKOTA

**Society News**—Dr William R. Winn, Fargo, was elected president of the North Dakota Academy of Ophthalmology and Otolaryngology at its annual meeting in Fargo, recently. Drs Charles N. Spratt, Minneapolis, and George M. Constans, Bismarck, were the speakers.

#### OHIO

**Epidemic Encephalitis at Fremont**—Eight persons died of epidemic encephalitis at Fremont during the two weeks preceding August 28, according to the *Chicago Tribune*. Dr Francis M. Teeple, county health officer, reported that the epidemic appeared to be waning at that time.

**Program of Hospital Obstetric Society**—A plan of action for the Hospital Obstetric Society of Ohio, formation of which was announced in *THE JOURNAL*, May 5, page 1506, was recently outlined by the president, Dr Arthur J. Skeel, Cleveland, and adopted by the society. It is proposed to sponsor the adoption of a continuous audit system of hospital obstetric mortality and morbidity, to develop a code of rules and regulations to govern hospital obstetrics, to further a uniform system of staff organization and control including both the regular and the courtesy or affiliate staffs, to support legislation that will compel conformity with the principles of such a code by institutions or persons unwilling to comply, to develop facilities for maternity cases throughout the state, and to encourage as nearly complete hospitalization of maternity cases as conditions in individual communities will permit.

#### PENNSYLVANIA

**Personal**—Dr Henry F. Ulrich has been appointed coroner of Snyder County to succeed the late Dr A. Jerome Hermann, Middleburg. Drs Edward Lyon Jr and James Stanley Smith were recently awarded the 1934 prize offered by the Williamsport Hospital staff to the interns submitting the best papers on subjects of interest to the medical profession. Dr Walter F. Donaldson, Pittsburgh, secretary of the Medical Society of Pennsylvania, has been made chairman of the health committee of the Pittsburgh Chamber of Commerce.

**Society News**—Drs Joseph H. Barach, Scott L. Koch and Laurence E. VanKirk, DDS, Pittsburgh, addressed a meeting of physicians from several counties under the auspices of the Clearfield Medical Society, Clearfield, recently, on various aspects of cardiovascular renal disease. At the annual meeting of the western section of the Fifth Council District of the Medical Society of the State of Pennsylvania, July 19, at Graeffenberg Inn, Franklin County, speakers were Drs Donald Guthrie, Sayre, president of the state society, on "Cardinal Symptoms of Duodenal Ulcer", John O. Bower, Philadelphia, "Reducing the Mortality of Appendicitis," and Howard K. Petry, Harrisburg, "A Challenge on the Early Stages of Mental Disorders."

#### Philadelphia

**Survey of Poliomyelitis and Encephalitis**—Dr J. Norman Henry, director of health of Philadelphia, has appointed a special committee of physicians to study poliomyelitis and encephalitis, as follows: Drs Courtland Y. White, Abraham M. Ornstein, George E. Johnson, Pascal F. Lucchesi, Randle C. Rosenberger, Daniel J. McCarthy, DeForest P. Willard, Frank W. Konzelmann, Edward A. Strecker and Howard C. Carpenter. The formation of the committee had no bearing on the incidence of the diseases in the community, it was said, but particular attention will be paid to methods of controlling any epidemic that may arise. The object is to study all questions relating to the epidemiology and methods of conveyance of the diseases, together with questions of susceptibility and contagion.

**Municipal Swimming Pools Contaminated**—An investigation conducted by the *Philadelphia Inquirer* early in August revealed that nearly all the swimming pools operated by the city were grossly contaminated because of laxness in supervision. It was charged that adequate precautions were not taken in the matter of requiring swimmers to bathe before entering the pools and that sufficient amounts of chlorine to

counteract the pollution were not being supplied. Following the exposure of these conditions by the newspaper, the state department of health made an inspection and reported that measures had been taken to eliminate the high bacterial count. The department recommended that before another summer season more adequate apparatus for chlorination be installed and that more frequent tests for chlorine content of the water be made.

#### TEXAS

**Society News**—A symposium on pancreatic disease will be presented before the Dallas County Medical Society, September 13, by Drs George D. Mahon Jr, Henry M. Winans and John L. Goforth. Drs Richard B. Grant Jr and Roland M. Searcy, Bryan, addressed the Brazos-Robertson Counties Medical Society, Hearne, July 10, on diarrheas and fractures of the forearm, respectively. Dr Winfred Wilson, Memphis, discussed hospital insurance at a meeting of the Childress-Collingsworth-Donley-Hall Counties Medical Society, at Childress, June 15. Drs Witten B. Russ and William E. Nesbit, San Antonio, among others, addressed the Gonzales County Medical Society, Gonzales, June 30, on "Danger of Deferring Operation for Cancer of the Stomach" and "Cardiac Conditions Simulating Acute Indigestion," respectively.

#### GENERAL

**Auxiliary Board Meeting**—The regular fall meeting of the board of directors of the Woman's Auxiliary to the American Medical Association will be held in Chicago at the Pearson Hotel, September 22. Mrs Robert W. Tomlinson, Wilmington, Del., is president of the Auxiliary.

**James Cooper Not an Authorized Solicitor**—James Cooper, who it is reported, has been obtaining money for subscriptions to various publications of the American Medical Association is not an authorized representative of the Association. Cooper has recently been reported in Indiana. He is described as about 22 years of age, 5 feet 10 inches in height, with a fair complexion.

**Changes in Status of Licensure**—The California State Board of Medical Examiners reports that at a meeting in San Francisco, July 9-12, the following action was taken:

Dr Harvey P. Charles, Berkeley, license revoked on records of his conviction of battery following alleged assault on two women who called at his office.

Dr Leman Dow Cruice, San Diego, license revoked following his conviction of narcotic violation now in McNeil Island Penitentiary.

Dr Oscar W. De Vaughn, Oakland, license revoked on record of conviction of criminal abortion and also record of subornation of perjury sentenced to San Quentin.

Dr Manuel M. Doria Jr, San Diego, license revoked July 12 on a charge of habitual intemperance.

The State Medical Board of the Arkansas Medical Society announces the following action:

Dr Junius Ruth, Rison, license restored January 10.

Dr Thomas B. Sylar, Holly Grove, license restored May 16.

**Program on Medicinal Chemistry**—At the semiannual meeting of the American Chemical Society in Cleveland, September 10-14, the division of medicinal chemistry will hear the following speakers, among others:

Dr Emil Bogen and Russell N. Loomis, Olive View Calif. Comparative Carcinogenic Effects of Common Agents.

Conrad A. Elvehjem, Ph.D., Madison, Wis. Effect of Iron and Copper Therapy on the Hemoglobin Content of the Blood of Infants.

Charles G. MacArthur, Buffalo, Chemical Analysis of the Central Nervous System of an Idiot.

Courtland L. Butler Jr, Ph.D., Alice G. Renfrew, Ph.D. and Leon and H. Cretcher, Ph.D., Pittsburgh. Cinchona Alkaloids in Pneumonia.

Dr Andrew Richard Bliss Jr, Memphis, Tenn. Absorption of Certain Drugs Through the Skin.

Paul Nicholas Leitch, Ph.D., secretary, Council on Pharmacy and Chemistry, American Medical Association, Chicago. Some Simple Short Cuts in Analysis of Unknown Medicinals.

Henry V. Farr, St. Louis. Significance of Some Impurities in Anesthetic Ether.

Clemmy O. Miller, Ph.D., Chicago. Analytic Method for Determining Scurvy Based on Ascorbic Acid (Ascorbic Acid).

David Klein, Ph.D., Chicago. Inaccuracies of Official Enzyme Assays.

**Diabetes in 1933**—The average death rate for diabetes in fifty cities of the United States in 1933 was 26 per hundred thousand of population, a slight reduction from the 1932 rate, which was 26.3. A compilation of deaths in 175 cities also shows a reduction from 24.3 to 23.8. These slight improvements may possibly foreshadow further decrease in the near future in the opinion of Frederick L. Hoffman, LL.D., consulting statistician of the Prudential Life Insurance Company. The highest rates in 1933 occurred in Utica, N. Y., with 60.5; Lancaster, Pa., 49.9; Williamsport, Pa., 49.2; Paterson, N. J., 48.8; Fall River, Mass., 45.8. The five cities with the lowest rates were Somerville, Mass., 2.8; Pueblo, Colo., 3.8; Fort Worth, Texas, 5.5; Newton, Mass., 5.6; and Gary, Ind., 6.1.

The five largest cities in the United States had the following rates: New York, 29.2; Chicago, 27.3; Philadelphia, 26.9; Los Angeles, 21.4; and Detroit, 16.9. A study of the rates according to sex in New York City showed that in 1932 the rate for men was 19.8 and for women, 38.9. These rates had increased since 1920 from 14.5 and 23.3, respectively. It is believed that the annual loss of life from diabetes in continental United States is about 30,000 deaths at present.

**American Academy of Ophthalmology and Otolaryngology**—The thirty-ninth annual meeting of the American Academy of Ophthalmology and Otolaryngology will be held in Chicago at the Sheraton Hotel, September 9-14. Professor Hans Lauber, Warsaw, Poland, will be the guest of honor and will deliver an address at the opening general session on "Diagnostic and Prognostic Importance of Ophthalmoscopy in Red-Free Light, with Special Reference to the Affections of the Optic Nerve and the Chiasma." Symposia will be presented on the tonsils, etiology of exophthalmos and conservative treatment of the nose, throat and ear. There will also be courses of instruction on histopathology, fundus clinics at Cook County Hospital and conferences on many special topics each morning. Among other speakers will be:

Dr. Charles H. Watkins, Rochester, Minn., Relation of the Use of Barbiturates to Agnucloeytic Angina

Dr. Marie F. Weymann, Los Angeles, Use of Sclerosing Solutions in Ophthalmic Therapeutics

Dr. Harry M. Weed, Buffalo, Divergence Paralysis Due to Head Injury

Dr. Arthur C. Jones, Boise, Idaho, Oil Cyst of the Orbit with Carcinomatosis

Drs. Max I. Folk and Samuel Soskin, Chicago, The Fundus Oculi in Diabetes Mellitus

A golf tournament will be held Wednesday afternoon, September 12, at Olympia Fields Country Club. The president, Dr. John M. Wheeler, New York, and Mrs. Wheeler will hold a reception Sunday afternoon, September 9. At a banquet and dinner dance Tuesday evening guests of honor will be Professor Lauber, Dr. Carl Koller, New York, in recognition of the fiftieth anniversary of the discovery of cocaine as a local anesthetic, and Dr. Wells P. Egleton, Newark, N. J., president-elect of the academy. Friday afternoon will be devoted to a visit to the Illinois Eye and Ear Infirmary.

## Government Services

### Civil Works Health Projects

A summary of the work accomplished on health projects sponsored by the U. S. Public Health Service as a part of the Civil Works Administration during the winter 1933-1934 appeared in *Public Health Reports*, August 17. The four projects recommended were a malaria control drainage program in the fourteen states in which malaria has been most prevalent; construction of sanitary facilities in small towns and unsewered outskirts of large cities; surveys to determine the extent of endemic typhus fever in rodents in important seaports, and the sealing of abandoned coal mines to reduce the acid wastes being discharged into streams used for water supplies. Health officers of the states were made agents of the federal health service for technical supervision. Amounts set aside for labor totaled approximately \$4,500,000 for malaria control, \$5,000,000 for community sanitation, \$1,000,000 for typhus fever surveys and \$1,500,000 for sealing coal mines. At the height of employment 28,000 laborers were at work on federal projects and in addition 53,000 were reported to be working on similar projects carried on by state and local authorities. Community sanitation projects were carried out in twenty-four states, employing 35,000 persons at the peak. Incomplete reports showed that more than 200,000 sanitary privies were constructed. In some communities in which increasing prevalence of typhus had alarmed the citizens, sources of infection were located and control measures instituted. The mine sealing operations were curtailed before they were completed, although about 7,000 openings of various kinds had been closed in states where it was possible to begin work immediately, Alabama, Pennsylvania and West Virginia. In other places surveys were completed, furnishing records to state departments of health covering location of mines discharging acid water. Other results considered worth while were the demonstration of the practicability of sealing, development of methods of air sealing under varying conditions, training of mining engineers and others in the methods, and creating interest of mine owners in the problem. The largest number employed on this project was 2,927 men and 24 women.

### The Aryan and Nordic Myths

In introducing a discussion on man's place in nature at the International Anthropological Congress in London the president, Sir Grafton Elliot Smith, F.R.S., the anatomist, said that at present it was of the greatest importance that anthropologists should reach some consensus on such problems as might be held to justify or excuse political action. If their discussions did nothing more, it would be a definite gain if they could impress on the world some respect for anthropologic truth and the generally admitted facts of race and culture. There was still some diversity of opinion as to the place where civilization first originated, although he himself had no doubt (He believes that it originated in Egypt). There was now evidence to show that whether it happened in Egypt, India or elsewhere, in any case it was the work of members of the race which, as Sergi taught, spread round the shores of the whole Mediterranean. There was no adequate reason for regarding this as in any sense due to any innate qualities or initiative or skill on the part of the members of that race, but rather to the historical circumstances that impelled the people living on the banks of the Nile to embark on those agricultural pursuits which led inevitably to the building up of civilization.

It was important to emphasize that fact at a time when distinctive qualities were being attributed to the Nordic race and the so-called Aryan people. Although the introduction of the term "Aryan people" must be attributed to Max Müller, it was important to note that in the face of intense criticism he was compelled to admit that "an ethnologist who speaks of Aryan race, Aryan blood, Aryan eyes and hair, is as great a sinner as a linguist who speaks of a dolicocephalic dictionary or a brachycephalic grammar." Those who insisted on the moral and intellectual qualities of the so-called Aryans and talked about primitive Aryan culture should be reminded that it was more than doubtful whether the Aryans did invent a primitive culture in any other way than in borrowing it from Babylon. Prof. A. J. Carnoy had demonstrated that the so-called primitive Aryan culture was derived from Babylonia. It was a fallacy to attribute cultural achievements and inherent mental aptitudes to different races. When one thought of the trenchant exposure of the Aryan fallacy by Huxley in 1890 it became an increasing matter of surprise that the facts of anthropology should be so flagrantly misused at the present time by using the word Aryan in the sense of non-Jewish.

A learned discussion by anthropologists of the term Aryan has followed in the *Times*. Sir Arthur Keith is alone in thinking that Max Müller may after all have been right. The term was originally and still is correctly applied to a group of languages comprising nearly all the European languages and Sanskrit, Zend and Persian. There must have been an original mother tongue from which these languages are descended. Keith argues that there must have been a people who spoke it. But this supposititious race is so remote that its physical characters cannot be described. A. C. Haddon, J. B. S. Haldane and C. G. Seligman in reply to Keith, point out that of the three great divisions of the European races—Nordic, Alpine and Mediterranean—no one can say which is descended from the original Aryan speaking stock and which acquired an Aryan tongue from it. However, it is generally admitted that the original Mediterranean race, of which the ancient Egyptians are an example, was non-Aryan. These professors therefore hold that "no specific racial connotation can be attached correctly to the philological term Aryan. The physical char-

acters of the three European races are so diverse that they can hardly have had a common origin less remote than the common stock of the white race, often called Caucasian, which definitely includes Jews and Arabs

#### Report on Cancer Research

At the annual meeting of the British Empire Cancer Campaign the report, which was presented and approved, stated that the main attack in the battle against cancer was now being directed against the cancer cell itself. Knowledge was increasing about the cell and about the chemical reactions that occur within it in the body. Such knowledge justified a sober optimism, for the enigma of the cancer cell might be looked on as the last defense of the disease. Mr Cecil Rowntree, surgeon to the Cancer Hospital, said that the report showed that the purposes for which the campaign were founded were being fulfilled in all directions. One purpose was the coordination of research and research organizations not only within Great Britain but throughout the empire. The recent steps in setting up a panel of international correspondents, whereby they had an accredited representative in each of the great scientific capitals, added to the accuracy and promptness of their foreign information. The investigations carried out at the Cancer Hospital and at the Middlesex Hospital suggested the possibility that the ultimate cause of cancer might be something of a chemical nature produced by disordered functions within the body itself. An admirable attempt to develop a new line of attack on cancer of the esophagus by intensive roentgen therapy had been made at St Bartholomew's Hospital. In his Garton prize essay Dr Colwell described the action of radiations on normal and malignant cells. All these provided encouraging indications of new and profitable avenues of research. In the direction of prevention they could point to great increase of knowledge of the nature of precancerous conditions, and in particular to the likelihood of a great diminution of the incidence of industrial cancer as the result of investigations into the carcinogenic agents in lubricating oils and other industrial materials.

#### ADVANCES IN THE RADIUM TREATMENT OF CANCER

On the curative side they could point to recent advances in radiation treatment. Partly in consequence of the campaign a silent revolution had been effected, for it seemed that the recent changes witnessed in the radium practice of the whole cancer world were no mere therapeutic experiments of passing interest but evidence of fundamental change in the picture of cancer treatment. The radium bomb, so called, was coming to be regarded as a necessity of all well equipped cancer centers. Fortunately the radium position had been materially eased by the discovery of radium deposits in Canada. It was not pretended that radium was a cure for cancer in the ordinary acceptance of the term, but in certain cases it gave results not hitherto obtained by any other method. One had only to point to cancer of the lip, tongue and uterus to realize the change in current practice. In these situations radium had in part or in whole replaced operative surgery. There was no hope that some sudden flash of genius would solve the cancer problem in a day. Every indication seemed to point to the necessity for laboratories and concentrated effort by skilled teams of workers who by pooling their experience and repeating and correcting one another's observations, would ultimately arrive at the truth.

#### Climate and Health

As Bournemouth is a famous health resort, it was appropriate that the president Dr S Watson Smith who is a local physician, should have taken Climate and Health as the subject for his address. The importance of sunlight to life, he said could not be overestimated but it was necessary to

impress on the community that our greatest natural friend the sun could be an equally important foe. Moderation was essential. Not only did excessive exposure to light rays entail fatigue and exhaustion, but it produced degeneration of the skin, such as may be seen in sailors. The external ears, lower half of the face and backs of the hands showed atrophy and pigmentation, on which warty growths appeared and later might assume a malignant state. But, properly used, the sun was of inestimable value. It had been proved that daylight and industrial efficiency were directly proportional.

#### British Equipment for British Hospitals

In England, once the home of free trade, economic nationalism is now the vogue. That health should be sought in British health resorts and hospital equipment and surgical instruments bought from British makers is now regarded as only right and patriotic. Lord Derby opened the medical section of British Industries House, a building that has recently been converted into a permanent exhibition center of British Empire merchandise, for the convenience of wholesale buyers at home and from overseas. The medical section will be a national buying center for hospitals and the medical profession. On the ground floor has been constructed a model hospital comprising a ward of twelve beds, two operating theaters and accessory rooms, all designed and furnished on the most modern lines. At one end of the ward is a semicircular sun balcony for convalescents. The larger operating theater is equipped with all the appliances needed for major operations. A physician and technical experts are permanently in attendance to explain and advise. The planning of the section has been supervised by a medical advisory council of which the chairman is Dr Cox, formerly medical secretary of the British Medical Association. The third floor of British Industries House is devoted to showrooms and showcases displaying British-made medical and surgical instruments. On the lower ground floor will be installed a manufacturer's pattern and sample department in which will be shown commodities that concern the lay side of hospital maintenance. The opening ceremony was attended by Lords Dawson, Horder and Moynihan, Sir Humphry Rolleston and Sir Holburt Waring, president of the Royal College of Surgeons.

#### Congress of French-Speaking Physiologists

The Congress of French-Speaking Physiologists, held at Nancy, was presided over by Prof Henri Fredericq of Liege. Among many interesting papers, attention is directed to the communication of Professor Lapicque of Paris on the autonomic nervous system and to another by Professor Bacque, who postulates the existence of chemical substances liberated by the excitation of the postganglionic fibers of the autonomic nervous system. As Bacque views the subject, the sensitizers (cocaine) and the paralyzants (ergotamine) exert their action not through a modification of the functioning of the nerve but by changing the physicochemistry of the excitable substance. Professor Roche of Marseilles read a paper on the comparative biochemistry of respiratory pigments, an interesting study on the hemoglobins and hemocyanines. The author emphasized the specificity of these substances depending on the species, and in the higher animals even on the individuals. This is a new manifestation of a specific characteristic of protein. In the protein portion of the hemoglobin molecule differences of composition have been found. Mr Delaunay of Bordeaux and Mr Polonowski of Lille discussed the metabolism of ammonia in invertebrates and vertebrates, respectively. It appears that ammonia plays an important part as an end product of the

disintegration of nitrogen compounds but represents only a transitory chemical stage before its fixation in other more stable atomic groups. It disappears therefore almost as soon as it is formed, either by transformation into urea or by giving rise to other compounds. Aside from these important monographs there were numerous others devoted to a consideration of various hormones, which subject appears at present to interest investigators most. The congress closed with an excursion to the hot springs resorts of the Vosges region.

#### Protection of Radios Against Noises

At the request of owners of radio receiving sets, who have become more assertive since the government has imposed a small tax on them, regulations have been promulgated to protect them against disturbing noises caused by electrical apparatus operated in the vicinity. Many complaints have been filed against the medical apparatus of radiologists and electrotherapists, and several lawsuits have been instituted by the neighbors of the latter, and in some cases the neighbors have won the suits. On the other hand, there are devices designed to protect radio apparatus against noises, and it is an easy matter for owners of radios to procure them. The minister in charge has endeavored in his decree to consider the rights of the two opposing camps. He has required that apparatus producing heavy electric power shall be provided with protective devices. Only certain types of motors require protection, which is accomplished easily if they are properly grounded. Electrical medical apparatus is, in principle, classed with household electrical apparatus, that is, it is low powered and the installation of insulating devices would entail expense, out of proportion to the advantages derived. This decision satisfies the owners of ordinary medical apparatus. Nevertheless, when a complaint is filed, no judgment can be pronounced until an opinion by a technical committee appointed by the minister has been rendered. It is impossible at present to prevent a diathermy apparatus from emitting radiations.

#### Lymphogranulomatosis and the Origin of Tabes

Much research has been undertaken to determine the action of the virus of the Nicolas-Favre disease on various organs when injected into the peritoneum of the monkey. It appears to cause a general infection of widely different forms, of which anorectal strictures have furnished recent proof. In 1933 Jonesco-Mihaesti, Tupa, Badenski and Wisner reported observations tending to prove that the virus of this disease, when administered to monkeys by the abdominal route, becomes localized in the nervous system and induces changes that resemble those of human tabes. Such observations, if confirmed, would modify present conceptions of the etiology of tabes dorsalis. Constantin Levaditi and Jean Levaditi, repeating the experiments of Jonesco-Mihaesti, communicated their results to the Academy of Medicine. The former hypothesis was not corroborated when the experiments were carried out on a plan that excludes the confusion of lesions due to the virus of the Nicolas-Favre disease and changes appearing in monkeys in captivity. For the present then the syphilitic virus remains the sole etiologic agent of tabes, conformable to the first conception of Alfred Fournier.

#### Deaths

Dr. Achille Louste, who has just died at the age of 58, was an eminent dermatologist. He was chief physician at the Hôpital St. Louis. He left many works on the treatment of syphilis.

Dr. Geoffroy, professor of histology and of pathologic anatomy at the Faculté française de médecine de Beyrouth has died under distressing conditions. Having occasion to handle in his laboratory the brain of a dog suspected of rabies, he feared he might become inoculated with the virus of rabies so he inoculated himself with antirabic vaccine. A few days

later, paralysis developed—something entirely unusual. In spite of the most excellent care, he succumbed. Professor Geoffroy was formerly a chief physician in the navy. He was a scientist of exceptional merit and an indefatigable investigator.

#### Hereditary Blindness and the Problem of Sterilization

Addressing the Freiburg Medical Society, Prof. W. Wegner pointed out that the problem of eugenics in connection with congenital blindness is a small part of the problem of sterilization for the prevention of hereditary disease. According to a purely legal interpretation of the German law, only total blindness comes within the sterilization law. From the standpoint of the ophthalmologist, however, those who, with greatly reduced vision, are unable to earn their living must be included. During recent decades, the number of blind persons in Germany has steadily decreased. It is thought that, through improved hygienic measures and the endeavors of ophthalmologists, a further decrease of 30, or even 40, per cent is possible. Aside from the war blinded, that would signify a reduction of Germany's blind population to about 22,000. The persons who can trace their blindness to heredity is placed at about 20 to 25 per cent of the total. Thus, by the application of eugenics a further reduction of the blind population is possible. Aniridia, which is a rare disorder, and zonular cataract, are subject to hereditary influences. The number of blind persons in Germany as the result of congenital cataract is estimated at 4,000. In addition, there are many weak-minded persons, whose number is unknown. Sterilization is demanded with reference to persons with aniridia or severe types of congenital cataract. The extreme prevalence of mild forms of congenital cataract requires the expert to be exceedingly cautious in his diagnosis of a case. As severe recessive hereditary disorders, mention was made of total color blindness, total albinism, retinitis pigmentosa and hydrophthalmos. The sterilization of persons with these severe hereditary disorders is demanded. In the prophylaxis of hereditary disorders, sterilization of all the offspring of persons with severe recessive hereditary disorders would be desirable, but it does not appear feasible at present. The only grave eye disorder of a recessive hereditary character is Leber's optic atrophy. Since the direct transmission of this disorder by manifest carriers is only remotely possible, the sterilization of such persons, although desirable, cannot be considered imperative.

Since most of the sisters of persons thus affected may transmit the disorder without it being necessary that the husband shall be predisposed, the ophthalmologist should demand the sterilization of the sisters of any person presenting Leber's optic atrophy. Such demands in themselves are justified, but they exceed the limitations of the sterilization law. Degenerative myopia is more important, since, by reason of the complications, it represents a greater handicap socially than the inherited recessive disorder. General applications of the sterilization law are unthinkable even in high-grade myopia, but the marital union of persons with high grade myopia should be prevented, since experience has shown that nearly all the offspring of such marriages are very near-sighted. Members of families in which high-grade myopia is frequently complicated by detachment of the retina should be prevented from having offspring. As the statistics on this subject are not the best, it is impossible to state just what can be accomplished by eugenic measures. It is difficult to establish any universal criteria for the application of eugenics in connection with hereditary eye disorders. Yet such criteria are essential in view of compulsory notification and the threatened penalty if such notification is neglected. To procure data for the establish-

ment of such criteria, it has been proposed that an ophthalmologic census of Germany's blind population be undertaken.

Professor Lohlein, director of the Freiburg University eye clinic, contributed a few remarks. One of the controversial points of this whole question is: What constitutes blindness? The sterilization law has obviously a condition in mind in which a person is "practically blind," and does not envisage theoretically complete blindness with absolute exclusion of light sensation, but even the notion of being "practically blind" may be conceived of in various ways. It may designate a condition in which a person is unable to find his way about in a strange region, or, on the other hand, it may signify that a person does not possess adequate vision to profit by the training received in an ordinary school or by preliminary training for the prosecution of ordinary callings. Every ophthalmologist has observed cases in which persons with scarcely one tenth of normal visual acuity are able to get along fairly comfortably in times of stress by reason of their grim determination, whereas many other persons with much better vision are, to all purposes, blind. Another controversial point is the relative frequency of hereditary blindness. No one can supply reliable statistics on this question, but possibly it may be said that the truth lies somewhere between Kraemer's figure of 3.85 per cent of all cases of blindness and Verschuer's estimate of 33 per cent, which is certainly exaggerated. Lohlein holds the view that it would be well to extend the application of the law as first formulated. Difficulties for the ophthalmologist begin at the point at which he has to deal with hereditary eye disorders that, in a certain percentage of cases, actually render the patient practically blind but that frequently are inherited in only a mild form, so that they influence visual acuity but slightly, as, for example, in the case of congenital cataract and in hydrophthalmos, which may appear in a group of brothers and sisters sometimes in grave sometimes in mild forms. Each individual case must therefore be judged on its merits. The problem is to discover why, in a group of siblings, the offspring of the same parental stock, some persons develop a grave and others a mild type of the hereditary disorder. The phenomenon may doubtless be explained by environmental influences, in the broadest sense of the term, or by a predominant influence of either parent. In the event of a close decision it must be determined to what extent some particularly valuable hereditary quality known to exist in the family may be given compensatory consideration, for example, when there is evidence of high musical talent or similar hereditary qualities, for it goes without saying that provision must be made for carrying over into coming generations hereditary qualities of an especially high order. Thus can be seen that the questions concerning persons with reduced vision are much more complicated than as regards persons with hereditary weak-mindedness, for seldom will there be any doubt about the need of preventing weak-minded offspring.

#### Reorganization of the Confidential Physicians in the Krankenkassen

A short time ago the krankenkassen were completely reorganized. In connection with many other changes, it is fortunate that the ambulatoriums, which the medical profession had long combated as undesirable for mass treatment, were closed (*THE JOURNAL*, April 28, 1934, p. 1414). At the same time, a thorough reorganization of the service of confidential physicians was undertaken, which formerly had often awakened the distrust of the insured and of that portion of the medical profession that had retained its independent practice. The confidential physicians are now full time officers, being engaged under a life contract and being entitled to draw a lifelong annuity on completion of their service period. They are prohibited from engaging in any form of outside activity other

than literary work and the estimation of degrees of disability. Part time confidential physicians are called on only for the performance of special tasks. The chief duty of the confidential physicians is to verify the diagnoses of the kassenarzt or, in some cases, to establish a diagnosis. The testing of the working capacity of insured members is of secondary importance in the lineup of their duties. The confidential physicians are under obligations, in every single case, to make their own diagnosis on the basis of a carefully prepared history and a thorough examination, with a setting forth of the scientific reasons for the opinions advanced. It is their duty to get in touch with the attending physician. A service of confidential physicians has been organized in Berlin at each of the twenty-nine administrative centers of the Allgemeine Ortskrankenkasse, and likewise at the administrative centers of the largest special ortskrankenkassen. At the centers that have a large number of members, complete "institutes" for confidential physicians, with a special laboratory and complete roentgen equipment, have been created, which do research for the confidential physicians of smaller administrative centers. In general, there is one confidential physician to from 20,000 to 25,000 insured. The daily performance of the confidential physician is placed at twenty examinations, in addition to extensive administrative work. For the more difficult laboratory researches a special institute is available.

To corroborate the diagnosis, special hospitals for observation have been provided, which deal solely with diagnosis. In these observation hospitals the average observation period is only 5.8 days, as compared with seventeen days in the general hospitals.

The numerical status has improved as a result of the reorganization of the krankenkassen. Whereas, in recent years, the average total number of insured members who were on the sick list was 1 per cent in excess of the average total for the reich, today that excess has been eliminated. This 1 per cent amounts at present for the Berlin ortskrankenkassen to about 8,800 patients, which, with an average daily sick benefit of 175 marks (\$0.68), amounts to 15,400 marks (\$6,000) a day, or 5,000,000 marks (\$2,145,000) annually, aside from all other expenses. The whole service of confidential physicians, including the cost of the physicians for the observation hospitals and the special laboratories and institutes, will cost, as nearly as can be estimated, 1,500,000 marks (\$585,000), so that, according to this computation, these additional expenditures would be offset by a decrease in the total average number of patients amounting to only 0.25 per cent.

Departments for the detection of the most important racial diseases have been created, namely, for tuberculosis, cancer, diabetes and rheumatism. In addition, a center has been established that deals with the heredobiologic scrutiny of the population of Berlin. To these centers just mentioned are sent the corresponding reports of all the service centers of the confidential physicians. These centers then deal further with these patients. It is hoped that in this way all unknown cases will be brought to the proper centers without delay. For example, the tuberculosis central carries out a systematic examination of all persons living in a household known to be tuberculous and, if indicated, inaugurates treatment of all persons infected and prophylactic treatment of all persons menaced. From 100 to 120 menaced children may be sent at one time to a bath establishment for children. Thus far this tuberculosis central has ferreted out more than 4,500 active cases of tuberculosis, about 40 per cent of which were unknown.

The diabetes central has detected so far more than 1,000 cases. The total number of manifest cases of diabetes in Berlin amounts to more than 10,000, with an additional 40,000 suspects. By means of a new method, it has proved possible to establish, as a rule the proper nutrition of patients within

a few days without hospital observation, solely with the aid of ambulant laboratory study. The other centrals function correspondingly. In association with the service of the confidential physicians, a special welfare service through welfare aid workers, who visit patients in their homes, has been created.

### ITALY

(From Our Regular Correspondent)

July 15, 1934

#### Meeting of Academy of Medicine

The Academy of Medicine met recently in Turin, under the chairmanship of Professor Tirelli. Bizzozero and Ferrari spoke on cutaneous allergic reactions in syphilis. The researches were carried out on more than 100 persons, on healthy persons who served as controls, and on a group of persons with tertiary manifestations. It developed that in syphilis there is frequently a hypo-ergy of moderate grade toward tuberculin, which is accentuated during the secondary exanthems and becomes attenuated with the disappearance of the exanthem. One observes often hypo-ergy also toward heterogenous proteins and living streptococci. In syphilitic patients with tertiary cutaneous manifestations, inconstant reactivity toward various antigens was observed in six patients. The speakers hold that this reaction is to be regarded as having also the character of specificity.

Rizzatti and Levi reported the results of treatment of epilepsy by the periodic introduction of air by the lumbar route. The experiments were carried out by the introduction of from 5 to 40 cc of filtered air every ten to fifteen days. In thirteen cases so treated they observed no serious disturbances. In seven cases they noted an appreciable diminution of the attacks, although they reduced the anticonvulsive treatment to from 0.05 to 0.10 Gm of phenobarbital.

Rizzatti and Martinengo reported hematologic data they had collected on the families of persons affected with dysthymia. Since persons presenting dysthymia have a marked lymphoid tendency, the speakers considered the phenomenon to be chiefly of a constitutional order and sought to find evidence of it in the family history of the patients. On studying into the histories of six families with typical cases of dysthymia they were able to find a lymphoid tendency sometimes in the maternal blood stream, and sometimes in the blood stream of the father, and in one case in both. They reported that as a rule this peculiarity of the blood affects preferably one sex of the family.

Segre spoke on the speech of laryngectomized persons. A person who has undergone laryngectomy may, through practice reacquire a form of speech, which will take the form of a pseudowhispering or a pharyngeal voice analogous to that observed in a person who has been subjected to tracheotomy but such a voice is not fully adequate. It is however, possible by means of careful reeducation to secure a phonation suitable for narration with a voice of the pharyngeal type.

#### The Kahn Reaction in Mental Patients

In 120 mental patients, Dr Visalli applied both the Wassermann and the Kahn tests. He found a certain degree of positiveness of the test in suspected patients and also in some who were not suspected. These results according to the speaker (who reported them to the Academy of Physical Sciences of Ferrara) support the idea that the syphilitic nature of mental diseases is more frequent than is supposed. The cases of syphilis would appear even more numerous if means of detection more precise and more specific than the Kahn test could be devised. The Kahn test gave negative results in some cases that were certainly syphilitic. The speaker holds that the Kahn test should be applied as a current method of research to all mental patients.

During the discussion, Ravenna stated that for some time the laboratory of the Ferrara Hospital had applied the Wassermann and Kahn tests in a parallel manner. He gave it as his impression that the Kahn test, although more sensitive than the Wassermann test, is somewhat less specific. Hence, from a clinical point of view, a positive Kahn test, unless it is supported by other data, does not seem to the speaker to be sufficient evidence to decide on the existence of a syphilitic infection. Rietti gave the results of his laboratory experiments with the various flocculation tests that had been proposed in recent years. He holds that at present none of these tests can replace the Wassermann test but can only supplement it. If the results are discordant and there are no anamnestic or clinical data that point to the existence of syphilis, great caution must be exercised in evaluating positive results of the flocculation tests.

#### Leonardo da Vinci's Knowledge of Embryology

Dr Mozzetti made a study of the embryologic drawings of Leonardo da Vinci and the notes appended thereto and reported to the Società medico chirurgica of Venice. In addition to the recognized priority with regard to the behavior of the fetus in the uterus and to the placental circulation, it seems probable that to Leonardo belongs the first description of the ductus venosus, which was named after Aranzio, and also the knowledge of the protective function of the amniotic fluid. The embryogenesis of the liver and the spleen and the growth of the fetus in the uterus were described and reproduced by Leonardo. He also gave the first account of placenta praevia centralis. In spite of the inevitable errors due to the times the name of Leonardo has acquired new splendor from a study of his drawings and notes and he has achieved the right to be regarded as one of the precursors of the obstetric and gynecologic disciplines.

### MOSCOW

(From Our Regular Correspondent)

Aug 5, 1934

#### The Fourth International Antirheumatic Congress

The fourth International Antirheumatic Congress was held at Moscow, May 3-7, under the presidency of Prof M P Konchalovsky. About 800 physicians took part, including 143 delegates from the Soviet Union and 100 from nineteen other countries. Thirty-nine reports were read half of them by members of the Soviet delegation.

The people's commissar of health G N Kaminsky, told the delegates about the following decisions of the government. In Moscow will be organized a permanent antirheumatic museum, in Sochi and Mazesta, rheumatic clinics, departments of the central institute for studying spas will be established at Moscow, a children's rheumatologic sanatorium will be built. At Moscow, Leningrad, Charkov and Odessa, medical institutes and institutes for qualification of physicians will be established. Besides this, the Soviet government has established two international prizes each of 1000 rubles for the best work on the clinical and social problems of rheumatism.

The scientific exhibits for the congress consisted of five departments. In the first were the conditions created for eliminating the causes of rheumatic morbidity in the Soviet Union. The second was devoted to balneologic treatment of rheumatic patients. Soviet spas and the organization of treatment were shown. The pathology of rheumatism was concentrated in the third department. The geographic spreading of acute rheumatism, different types and methods of treatment were shown. The other departments of the exhibition concerned materials about rheumatism in children and industrial workers. Methods of combating rheumatism among miners, seamen, railway workers, motor transport workers and machine builders were shown.

As the congress proceeded in the Moscow House of Scientists, the delegates' chairs had radio ear phones and all reports were translated into Russian, English, German and French.

The first day was devoted to the clinical side of acute rheumatism. Prof. M. P. Konchalovsky explained rheumatism according to the allergic theory and denies the presence of a specific infectious agent. In the discussion, Prof. D. D. Pletniev of Moscow spoke on disturbances in the peripheral blood stream during acute rheumatism. Professor Faar of Germany demonstrated that the Aschoff nodes of the heart are more clearly manifested in children than in adults. Professor Schlesinger of London showed that acute rheumatism is closely connected with meteorological and geographic factors. Prof. L. B. Buchstab of Odessa spoke about a biologic test for rheumatism that he and dozent Jassimovsky worked out. A pathologico-anatomic preparation of rheumatic lesions of the valvular system was demonstrated by Prof. V. T. Talalajev of Moscow and Dr. Iolo of Finland.

The second topic, indications for the balneologic treatment of rheumatism, was discussed May 5. Prof. G. M. Danichevsky of Moscow illustrated the method of choosing patients who are to be sent to the soviet health resorts. In soviet Russia at the beginning of 1932 there were 232 mud lakes, 163 salt lakes, 301 hydrogenic sulphide springs, 272 carbonic acid spas, 92 warm springs, 8 radioactive spas and 650 other mineral spas. One million eight hundred thousand patients visited the soviet health resorts and rest houses in 1933, 135,000 rheumatic patients were treated in health resorts during 1932.

Prof. S. S. Nalbandov of Odessa spoke of indications for mud treatment of the peripheral nervous system. His material includes 2,632 cases. The best results are obtained in the mud treatment of neuralgia with 91.6 per cent of improvement.

Professor Pisani of Italy gave a classification of rheumatic diseases. Prof. N. A. Valedinsky of Moscow spoke about the influence of hot hydrogen sulphide baths on the hemodynamic and trophic processes in cardiovascular diseases.

The third subject was rheumatism of transport workers, mine workers and metal workers—the significance of the occupational factor in rheumatic diseases. Prof. I. G. Gelman of Moscow read a paper on rheumatism among machine builders. In connection with the mechanization of industry, the rheumatic morbidity continuously decreases. It is most evident in the auto tractor industry, 41 per cent less, and in general machine building industry, less by 27 per cent. The principal rheumatogenic factors are muscle strain, static work requiring an incorrect position of the body and overheating, with currents of air and unequal cooling, minor traumas and long contact with cold metal in workshops. The most important rheumatic diseases seen among machine builders are myositis and myalgias (13 to 1,000 workers), acute neuralgias (0.9 to 1,000) and chronic articular rheumatism (0.7 to 1,000). Professor Platte of Germany read a paper on the conditions in mines and in metal works.

The final meeting of the congress was held in the Palace of Culture of the proletarian district of Moscow. There were present many workers who greeted the congress.

The fifth Antirheumatic Congress will be held in Lund, Sweden, in September 1936.

After the sessions of the congress the delegates divided in several groups and made a trip to the soviet health resorts and spas.

#### Institute of Experimental Medicine

The government published a decree about the removal of the Institute of Experimental Medicine from Leningrad to Moscow. The architectural projects of the institute's buildings are ready. They will be built in the style of the Italian renaissance. It is proposed to build stomatologic, pediatric and neuropsychiatric clinics, laboratories for physiology, morphology,

biology, biochemistry and biophysics, a hall for 1,500 people for international congresses, a library consisting of 700,000 volumes and other auxiliary buildings. About 100,000,000 rubles will be spent on the building of the institute during the second five year plan (1932-1937). When the buildings are finished, the Institute of Experimental Medicine will be the largest scientific and practical medical establishment in the world.

#### The Death of R. R. Vreden

Prof. Roman Romanovich Vreden died, February 7, in Leningrad, at the age of 67. During the Russian-Japanese war Professor Vreden was chief surgeon at the front. From 1906 he was the director of the St. Petersburg Orthopedic Institute, from 1918 he was professor of orthopedic surgery in the Leningrad Medical Institute and from 1924 he directed the orthopedic department of the State Traumatologic Institute. He was the founder of orthopedic surgery in Russia. He published more than a hundred scientific works, the best known being a practical manual.

#### JAPAN

(From Our Regular Correspondent)

June 30, 1934

#### National Sickness Insurance

Sickness insurance, which has been in force for the last seven years, has developed satisfactorily, although it was limited to a small part of the laboring classes. Now the government has made public a new plan of national sickness insurance which will be made on a large scale and over a large part of the country. The authorities say that the scheme is so large that three or five years will pass before it can be fully enforced. This system includes all except those who have a large income and those who are not able to pay. Sickness and accidents should be insured, but death and childbirth may be included if wanted. It is believed premature to add any further insurance now. The insurer will be any self-governing community and should be a territorial body—a town, city or village. As an exception, men of the same trade may be permitted to organize an association. In the territorial association all the residents should be insured compulsorily. Five or six hundred units will be established every year, and twenty years will probably be required to complete this system all over the country. The insurance allowance in kind is the rule and the cash allowance is the exception. As one kind of insurance is apt not to suit the circumstances in different districts, the details are entrusted to each association or body but under close superintendence and guidance of the government. The expenses should be paid by the members but the state, city, town or village may give a subsidy. Freedom of choice of physicians will be given.

To mediate disputes about the medical contracts, an office will be established. The insurance will be different according to the circumstances of each locality, and those members who are not to be given an allowance will be reimbursed to a certain limit.

It is anticipated that over 30,000,000 persons will be insured out of 50,000,000 persons who qualify for insurance. When this system has been completed, the present positions of the practitioners will have to be entirely changed.

#### Diphtheria Among Silk Mill Workers

Cases of diphtheria in 1933 amounted to 28,518 throughout the country, with 5,270 deaths, a much higher rate than in ordinary years. In Tokyo and in its suburbs there were 6,066 cases, which was 2,000 cases more than usual. There were 10.28 cases per 10,000 of population. There is a silk reeling mill where 145 girls, 16 men workers and 11 members of the owner's family lived in the dormitory. This mill stands in a village with a population of about 7,500, within two hours run by train from Tokyo. In this village there were eight cases

of diphtheria in 1931, three cases in 1932 and eleven cases in 1933. But on April 10 this year, in this mill, there broke out one case, by May 13 the outbreak amounted to forty cases and twenty carriers. All of these were slight attacks and in a week or two all the patients left the isolation hospital and no deaths were reported. In Tokyo and its vicinity 85 per cent of the patients were children under 10 years of age. The metropolitan police board is now encouraging immunization, which has so long been neglected among adults, especially in factories.

#### Outbreak of Encephalitis

As was expected, summer encephalitis has broken out in a few districts, one of which is the prefecture of Okayama. By the end of June more than fifteen cases were reported. Dr. Shoji Takeda, director of the Kobe Prefectural Hospital, has presented a report on this disease from the standpoint of climatic and geographic conditions. He says that more than two cases in the same family have never been found. The cases are widely distributed, but every summer cases occur in the same place. Most of the patients are more than 40 years of age. In the last ten years the largest number of cases occurred in 1924 (827 cases), 1926 (385), 1927 (319), 1929 (362) and 1933 (152). In these years there was little rainfall and the heat was intense in August and September. No matter how violently it raged in the hot months, the cool fall season never failed to cause this disease to disappear completely. The disease occurs chiefly in the three prefectures lying on the coast of the Inland Sea, and the number of the cases for the past ten years has amounted to 6,730. These prefectures are the chief salt-making districts in Japan. In the salt manufacturing industry little rainfall and high temperature are most necessary. Most cases are found in the farm villages and but few in the seashore town or villages.

#### Admiral Togo and His Family Physician

The death of Admiral Togo in May disclosed an episode of nobility of character of both the patient and the family physician. Dr. Naonjiro Kato, the admiral's attending physician, was merely a private practitioner and was almost unknown except among his patients. He was neither a famous professor nor a noted director of a big hospital, but he enjoyed the confidence of this great hero over thirty years and he was the medical attendant who was at the deathbed. It has come to be known since the admiral's death that Dr. Kato was a man of deep sincerity and so humble that he never showed pride at being Togo's attending physician. Whenever the admiral fell sick he seldom called other physicians in consultation, but was so careful that he went quietly to prominent practitioners in the capital to ask advice. He was a faithful student of medicine and regularly attended the short course given in the Tokyo Imperial University Medical Department for the past ten years that he might keep up with the progress of medicine. To honor him, his friends and associates and the graduates of the Nippon Medical College held a meeting and this story is widely told as an example of the ideal relation between physician and patient.

#### Cancer Research Institute Completed

The completion of the new buildings of the Cancer Research Institute was celebrated, June 20. Prince Fushimi, the president of the Cancer Research Society, was present. Dr. M. Nagayo is the new chief and Dr. R. Inada is the new director of the hospital attached to it. To assist in this work the new Mitsui Foundation has offered to the institute a quantity of radium, which is reported to have cost a million yen and to consist of 5 Gm. of radium bromide and radium sulphate to be bought in the Belgian Congo, Africa. This is the largest single amount of radium that Japan has ever had.

## Marriages

NORMAN JAMES HAVERLY, Lieutenant Commander, M. C., U. S. Navy, Boston, to Miss Agnes Katherine Gordon of Brookline, June 30.

JOSEPH E. O'DONNELL, Champaign, Ill., to Miss Palma Louise Utke of Enderlin, N. D., in Chicago, August 19.

E. TERRILL MONTGOMERY, Garden City, N. Y., to Miss Joan Marie Kimble of Honesdale, Pa., June 16.

ROLAND M. WEBSTER, Strawberry Plains, Tenn., to Miss Clara Evelyn Brown of Florence, Ala., June 9.

PERRY DAVID MELVIN, Ancon, Canal Zone, to Miss Judith Standard Fowler of New Orleans, August 10.

PHILIP WILHELM MORGAN, Emporia, Kan., to Miss Alfreda Neal of Melvern at Kansas City, Mo., July 7.

HARVEY NATHANIEL MIDDLETON, Anderson, Ind., to Miss Stella B. Walker of Indianapolis, June 16.

WILLIAM HUGH MILLER, New Carlisle, Ohio, to Miss Margaret Rose Dillon of Middletown, June 2.

W. BURLEIGH MATTHEW, Lafayette, Ind., to Miss Ruth Suzanne Adams of Beech Grove, June 1.

HARRY DALE MOWRY Ambridge, Pa., to Miss Mildred Hatfield of Harrington, Del., August 21.

HIRAM BURNARD MORGAN, Inman, S. C., to Miss Georgia Marie Dunn of Charleston, June 14.

PAUL THOMAS O'BRIEN, Menasha, Wis., to Miss Margaret Mary Dohr of Appleton, July 31.

ISAAC NEWTON KUGELMASS to DR. ELLA H. FISHBERG, both of New York, August 18.

EDGAR MAYER to Mrs. Rheta Guggenheim Jaffe, both of New York, July 11.

HARRY TABACHNICK to Miss Lillian Polli, both of Milwaukee, June 25.

SILVESTER DARLING to Miss Helen Barnes, both of Milwaukee, June 25.

## Deaths

Archibald E. Baker of Charleston, S. C., Medical College of the State of South Carolina, Charleston, 1889, clinical professor of gynecology at his alma mater, fellow of the American College of Surgeons, past president of the Tri-State Medical Association and the South Carolina Medical Association, formerly councilor of the first medical district of the South Carolina Medical Association, owner of the Baker Sanatorium, aged 71, died suddenly, July 31, at his summer home on Folly Island, of heart disease.

Edwin Caldwell Simonton, Shreveport, La., Tulane University of Louisiana School of Medicine, New Orleans, 1913, member of the Louisiana State Medical Society, fellow of the American College of Surgeons, on the staffs of the North Louisiana Sanitarium, Shriners' Hospital for Crippled Children, Tri-State and Shreveport Charity hospitals, aged 48, died, July 31.

Julius Eduard Lehmann, Winnipeg, Manit., Canada, University of Toronto Faculty of Medicine, 1893, M.R.C.S., England, and L.R.C.P., London, 1901, formerly associate professor of clinical surgery, University of Manitoba Faculty of Medicine, fellow of the American College of Surgeons, on the staff of the Winnipeg General Hospital, aged 66, died suddenly, July 3.

William Francis Freeman, Los Angeles, University of Toronto (Ont.) Faculty of Medicine, 1883, and Faculty of Medicine of Trinity College, Toronto, 1883, aged 77, for many years resident physician to the Santa Fe Coast Lines Hospital, where he died, June 6, of arteriosclerotic heart disease.

John James Walker, Montreal, Que., Canada, McGill University Faculty of Medicine, Montreal, 1906, demonstrator in medicine at his alma mater, health officer of Ste. Anne de Bellevue, 1913-1914, aged 53, for many years on the staff of the Royal Victoria Hospital, where he died, May 4.

Andrew G. Payne of Greenville, Miss., Kentucky School of Medicine Louisville 1893, fellow of the American College of Surgeons, past president of the Mid-South Post Graduate Medical Assembly, on the staff of the King's Daughters' Hospital, aged 65, died, July 31, of heart disease.

George Weare Weymouth @ Lyme, N H, Dartmouth Medical School, Hanover, 1882, in 1932 was presented with a gold medal marking the completion of fifty years' membership in the New Hampshire Medical Society, aged 77, died, May 30, in the Mary Hitchcock Hospital, Hanover, of coronary occlusion

William James Boyd, Oklahoma City, Okla, University of Buffalo School of Medicine, 1895, formerly professor of gynecology, Epworth College of Medicine, veteran of the Spanish American War, aged 73, died, July 13, in Colorado Springs, of cerebral hemorrhage

John M Johnson, Giddings, Texas (licensed in Texas under the Act of 1907), member of the State Medical Association of Texas, for many years member of the state legislature, formerly county health officer, aged 64, died suddenly, May 14, of heart disease

Harry Lyman Putnam, St Petersburg, Fla, Bellevue Hospital Medical College New York, 1890, member of the Florida Medical Association, past president of the Pinellas County Medical Society, aged 70, died, July 27, in a hospital at Asheville, N C

John Edward Simpson, Sturgeon Bay, Wis Bennett College of Eclectic Medicine and Surgery, Chicago 1901, served during the World War formerly city health officer aged 62, died, July 24, in the Wisconsin General Hospital, Madison, of bronchopneumonia

Joseph A Archambault, Essex Junction, Vt, University of Vermont College of Medicine, Burlington, 1901, member of the Vermont State Medical Society formerly instructor in medicine at his alma mater, aged 59, died suddenly, May 31, of heart disease

Thomas Boykin Clegg @ Greenville, S C, Emory University School of Medicine, Atlanta, Ga, 1925, on the staff of the Shriners' Hospital for Crippled Children aged 37, was drowned, July 23, while fishing in the surf of Seabrook Island, near Charleston

Patrick Joseph Barrett, Utica N Y Albany Medical College, 1892, member of the Medical Society of the State of New York, served during the World War, on the staff of St Elizabeth's Hospital, aged 63, died suddenly, July 16, of heart disease

James F Barnwell, Johnson City, Texas (registered in Texas, by the state board of medical examiners, under the Act of 1907), county health officer, formerly bank president and school trustee, aged 59, died, June 16, of carcinoma of the spine

Morris Hirsch Kahn, New York, Cornell University Medical College, New York, 1909, fellow of the American College of Physicians, formerly on the staff of the Beth Israel Hospital, aged 45, died, July 13, in the Mount Sinai Hospital

Thomas Ralph Castles, Albia, Iowa, Northwestern University Medical School, Chicago, 1907, member of the Iowa State Medical Society, aged 52, died July 29, in the Iowa Methodist Hospital, Des Moines, of essential hypertension

Richard Calvin McClure, Kansas City Mo, University Medical College of Kansas City, 1900, member of the Missouri State Medical Association, formerly a dentist, aged 62, died, May 19, of hypostatic pneumonia and Parkinson's disease

Louie Elsworth Langley, Williamsport, Pa, University of Maryland School of Medicine, Baltimore, 1910, member of the Medical Society of the State of Pennsylvania on the staff of the Williamsport Hospital, aged 49 died May 31

Horace Thea Fortner, Jellico, Tenn University of Tennessee Medical Department, Nashville 1925 member of the Tennessee State Medical Association, aged 34, was drowned, August 10, in Harrington Lake, near Danville, Ky

Arthur Stevenson McElroy, Ottawa, Ont Canada McGill University Faculty of Medicine Montreal Que 1897 for many years on the staff of the Ottawa Civic Hospital, aged 65, died, April 20 of cerebral hemorrhage

James Lambert Melvin, Guthrie Okla John A Creighton Medical College, 1896, past president of the Logan County Medical Society, aged 78 died July 24, in Bartlesville, of toxemia as the result of prostatitis and cystitis

Heman Rowlee Bull @ Grand Junction Colo, Jefferson Medical College of Philadelphia, 1887 fellow of the American College of Surgeons, for many years on the staff of St Mary's Hospital, aged 71 died, June 21

Alfred Napoléon Rivet, Montreal, Que., Canada School of Medicine and Surgery of Montreal, 1888, emeritus professor of toxicology at his alma mater served during the World War, aged 68 died April 21

Farrar Burr Parker, Long Beach, Calif, Tulane University of Louisiana School of Medicine, New Orleans, 1916, served during the World War, aged 48, died, June 26, of cardiovascular renal disease

John G Motley @ Henderson, Texas, University of Louisville (Ky) School of Medicine, 1891, past president of the Rusk County Medical Society, aged 71, died, June 17, in a hospital at Shreveport

Gershon Campbell Bryant @ Milan, Tenn, Memphis (Tenn) Hospital Medical College, 1903, past president of the Gibson County Medical Society, aged 58, died, July 22, of auricular fibrillation

William N Howard @ Cape Girardeau, Mo, St Louis Medical College, 1890 for many years member of the local board of health on the staff of St Francis Hospital, aged 71, died, July 29

Marjorie Sharps Jefferies Wagoner, Bryn Mawr, Pa, University of Pennsylvania School of Medicine, Philadelphia, 1922, physician to Bryn Mawr College since 1924, aged 37, died, June 22

Rafael Velez Lopez, Rio Piedras, P R Universidad Central de España Facultad de Medicina, Madrid Spain, 1897, member of the Medical Association of Puerto Rico, aged 62, died, June 8

J A Emile Choquette, St Bruno, Que, Canada, School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, 1900, aged 58, died, March 4

Frank F Fisk @ Price, Utah, Rush Medical College, Chicago, 1897, vice president and past president of the Carbon County Medical Society, aged 66, died, July 21, of heart disease

Burton B Buck @ Waterville, Ohio, Eclectic Medical Institute, Cincinnati, 1899, aged 71, died, August 3, in the Women's and Children's Hospital, Toledo, of cerebral hemorrhage

Benjamin Franklin Parrish, Midway, Ky Bellevue Hospital Medical College, New York, 1890 aged 68, died, July 11, in the Good Samaritan Hospital, Lexington, of heart disease

Michael Timothy Collins, Sedalia, Mo, Medical College of Ohio, Cincinnati, 1889, member of the Missouri State Medical Association, aged 76, died, July 20, of cerebral hemorrhage

William Edgar Christie @ Philadelphia, Jefferson Medical College of Philadelphia, 1917, on the staff of the Presbyterian Hospital, aged 40, died, July 29, at Beach Haven, N J

Francis Eugene Brennan, Flushing, N Y New York Homeopathic Medical College and Hospital, 1894 aged 61, died suddenly, July 30 at his country home in Cold Brook

Sylvain Beer Wolff, Opelousas, La Johns Hopkins University School of Medicine, Baltimore, 1914, past president of St Landry Parish Medical Society, aged 43, died, June 13

Charles Deems Bell, Wilmington, N C, University of Maryland School of Medicine, Baltimore, 1883, aged 76, died, June 17, in the Bulluck Hospital, of coronary thrombosis

James Daniel Marion Black, South Fork Mo Memphis (Tenn) Hospital Medical College, 1890, member of the Missouri State Medical Association, aged 72, died, May 14

Joseph Patrick O'Hanlon, Brooklyn, Long Island College Hospital, Brooklyn, 1891, aged 63, died, July 5, in the Hamilton Hospital, following an operation for cholelithiasis

Charles James Devlin, Swissvale, Pa, Jefferson Medical College of Philadelphia, 1916, member of the Medical Society of the State of Pennsylvania, aged 45, died, June 20

James Palmer Rankin, Stratford, Ont, Canada, Faculty of Medicine of Trinity College, 1878 formerly member of the city council and school board, aged 79, died, June 15

Preston Charles Jenkins, Roanoke, N C, Bellevue Hospital Medical College, New York, 1873, past president of the Bertie County Medical Society, aged 84, died, July 5

Evan Ellis Owen, Louisville, Ky University of Louisville School of Medicine, 1911, served during the World War, formerly city health officer, aged 45, died, July 20

Franklin W Palmer, Chatsworth, Ill, Barnes Medical College, St Louis, 1898, aged 61, was drowned, July 6, while fishing in the Kankakee River near Wilmington, Ill

Joseph Rymal Smith, Grimsby, Ont, Canada Victoria University Medical Department Coburg 1892, aged 67, died, April 1, in the Hamilton (Ont) General Hospital

Joseph William Stringer, Taylorsville, Miss, Mississippi Medical College, Meridian, 1909 aged 61, died, June 24, in a hospital at Laurel, of cerebral hemorrhage

David Finlay Marr ☉ Bradford, R. I., Tufts College Medical School, Boston, 1911, aged 57, died, May 15, of adenocarcinoma of the left ureter, with metastases to the liver

James Luther Moore, New Stanton, Pa., University of Pittsburgh School of Medicine, 1932, aged 32, died, in July, at the Westmoreland Hospital, Greensburg

Henry Deischer Stichter, Philadelphia, University of Pennsylvania School of Medicine, Philadelphia, 1889, aged 68, died, July 14, of carcinoma of the stomach

Samuel P. Deem, Rutland, Ohio, Baltimore Medical College 1893, member of the Ohio State Medical Association, aged 70, died July 5, of angina pectoris

H. Allen Booth, Pacific, Mo., Missouri Medical College St. Louis, 1886, aged 77, died, July 26, in the Barnes Hospital, St. Louis, of uremia and arteriosclerosis

Mathias Borts ☉ Cleveland, University of Wooster Medical Department, Cleveland 1881, aged 81, died, July 22, of arteriosclerosis and cerebral hemorrhage

Jonathan Titus McDonald, San Francisco Cooper Medical College, San Francisco, 1884, aged 81, died, May 31, of angina pectoris and coronary sclerosis

Elmer Grant Paxton, Cedar Rapids Iowa Ohio Medical University, Columbus, 1896, aged 64, died July 15 of paralysis agitans and arteriosclerosis

Mary Francilla McCrillis, Quincy, Mass. Boston University School of Medicine, 1882, aged 77, died July 20, in the Glenside Hospital, Boston

Thomas Edward Standifer, Turkey, Texas, Louisville (Ky.) Medical College, 1899, aged 70, died, May 20, in a sanatorium at Oklahoma City

George Arthur Schmidt, Cobalt Ont., Canada, Trinity Medical College, Toronto, 1899, aged 62, died, June 25, in the Toronto General Hospital

Max Von Beust, New Albany, Ind. Hospital College of Medicine, Louisville, Ky. 1881, aged 80, died May 24, of chronic cystitis and uremia

Erle Edson Benedict ☉ Minneapolis University of Minnesota Medical School, Minneapolis 1901, aged 57, died August 8, of heart disease

William Allen McKelvey, Opolis, Kan. St. Louis College of Physicians and Surgeons, 1901, aged 70, died, June 13 in a hospital at St. Louis

Atticus Gwynn Blanton ☉ Sonora Texas, Chattanooga (Tenn.) Medical College 1907, aged 52, was killed July 27 in an automobile accident

Edward Wesley Harrison, Winfield Iowa Keokuk (Iowa) Medical College, 1894, aged 66, died suddenly, July 6 of cerebral hemorrhage

William T. Simrall, Mount Sterling Ky. Louisville Medical College 1873, aged 92, died, July 22 in Ellicott City, Md., of heart disease

William Witter, Norwich Conn. Yale University School of Medicine New Haven, 1865, aged 93, died suddenly, May 27, of heart disease

Amos Wright Campbell, Prince Albert Ont. Canada Victoria University Medical Department, Coburg 1880, aged 84, died, June 12

Charles W. Piper ☉ Chicago, Chicago Medical College 1891, aged 69, died, July 11, of coronary occlusion and arteriosclerosis

Clarence Joseph Pullen ☉ Georgiana, Ala. (licensed in Alabama in 1905), aged 60, died July 15, in a hospital at Greenville

Thomas J. Gowan, Hornings Mills Ont., Canada Western University Faculty of Medicine, London, 1892, aged 75, died April 28

Charles Manley Foster, Toronto Ont. Canada Victoria University Medical Department, Coburg, 1884, aged 74, died April 9

Orville B. Yager, Glencoe Ky. Miami Medical College Cincinnati, 1867, Civil War veteran, aged 92, died, May 28

Margaret Cowan Calder, Wingham, Ont., Canada University of Toronto Faculty of Medicine, 1907, died, in April

Christian Heidemann, St. Louis Marion-Sims College of Medicine, St. Louis, 1892, aged 63, died suddenly, June 15

Alexander Kahn, Philadelphia Jefferson Medical College of Philadelphia, 1881, aged 75, died, May 12

Samuel Moss ☉ Philadelphia, Jefferson Medical College of Philadelphia, 1909, aged 52, died, June 29

William Bernard McKeon, Troy N. Y. Albany Medical College 1915, aged 42, died June 19

## Correspondence

### MECHANISM OF EXOPHTHALMOS

*To the Editor*—The editorial on "The Mechanism of Exophthalmos" in THE JOURNAL, June 30, quotes what is termed "this curious statement" from my recent textbook "Diseases of the Nervous System" "Apart from gross neoplastic and inflammatory lesions of the orbit, the mechanism of exophthalmos is still little understood" Your comment is "Nevertheless the mechanism of exophthalmos is well understood though the knowledge would seem to be poorly disseminated."

If the writer of your leader had done me the honor of quoting the article on exophthalmic goiter in my textbook, he would have found the explanation of exophthalmos which he proposes fully discussed and the conclusion drawn that "there is probably overaction of part of the ocular sympathetic fibers, causing retraction of the upper lids and some degree of exophthalmos" I am familiar with the various papers quoted in the leader and I agree that the muscles described by Landstrom exist and also that stimulation of the cervical sympathetic in animals will produce exophthalmos. In spite of this, however, I do not know of any proof that the exophthalmos of exophthalmic goiter is produced in this way. Indeed, certain points make it difficult to believe that overaction of the ocular sympathetic affords the whole explanation. Cunliffe Shaw has shown that section of the cervical sympathetic in exophthalmic goiter does not cause diminution in the exophthalmos. Numerous surgical studies of the orbital contents in exophthalmic goiter, especially those of Naffziger, have revealed in many cases intense edema of the orbital fat and extra-ocular muscles, with lymphocytic infiltration and, in the late stages, fibrosis. These changes may, of course, be secondary to the exophthalmos, though it seems to me more probable that they are its cause. Even if the exophthalmos is solely due to contraction of the smooth muscle of the orbit, it is not known whether this is produced by excitation of the sympathetic nervous system centrally or peripherally, nor whether the hypothetical excitation of the sympathetic is brought about by normal or abnormal thyroid secretion, or in some other way.

I have a fairly full acquaintance with the papers on exophthalmos which have been published during the last thirty years and I have discussed the problem with ophthalmologists, pathologists and physiologists. It is disappointing to have to admit that I remain of the opinion expressed in my book that "the mechanism of exophthalmos is still little understood"

W. RUSSELL BRAIN, London

### GROWTH FACTOR FROM ANTERIOR PITUITARY

*To the Editor*—I take this opportunity to add my word of commendation to the thousands which I know you have already received on the leading editorial, "Antihormones" in THE JOURNAL, August 18. Dr. Cushing undoubtedly issued a sound note of warning against the indiscriminate use of endocrine products and I am pleased to see you again warning the doctors about so-called isolated active principles. I have in mind chiefly or particularly the extract of the anterior lobe of the pituitary which I believe is now known to produce a growth factor. My research on cancer cases at the autopsy table has led me to believe that in this condition the anterior lobe is hyperactive. For this reason I cannot help but feel that you have shown the part of wisdom in proclaiming your announcement.

GEORGE A. WYETH M.D., New York

## Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

### ENCEPHALITIS AND NARCOLEPSY

*To the Editor*—Owing to the fact that I am pretty well muddled over the following terms I am taking the liberty of asking you for assistance: encephalitis, encephalitis lethargica, sleeping sickness and narcolepsy (sleeping sickness not the African type). Up to last evening at a staff meeting of our hospital I thought I had a fairly good idea of the differentiation from their names as well as the pathology. In the last few years, different members have had all told four cases. Three of these cases have been confirmed in diagnosis by men of good reputation away from here. The fourth is the one in particular that has put me out. One of the cases confirmed by Dr. Dowling of the Mayo Clinic and Dr. Stanley Cobb of Boston is in my own family. The one in question has been diagnosed encephalitis by one of the local men. My own idea was that encephalitis simply indicated that there is or was something wrong with the gray matter, such as a tumor, injury, disease or malformation. And I called the case encephalitis of narcoleptic type of a mild form. That precipitated an argument as most of the men felt that encephalitis was not a general term but specified the disease. We are in the same muddle about the pathology. My idea is an edema or boggy-ness of the base of the brain. I am unable to connect the following symptoms coming from the spinal nerves: intermittent loss of control of bowel and bladder, epileptiform seizures and so on. I have read all the articles in *THE JOURNAL* and Dr. Dowling's pamphlets. Will you please give me the titles of articles and prices with address of place to purchase them?  
J R WILSON MD Bennington Vt

**ANSWER**—In spite of the usage of physicians confronted by these perplexing cases, the latest Dorland, Gould and Steadman dictionaries are a unit in distinguishing these fundamental differences.

Encephalitis (Dorland) inflammation of the brain.  
Epidemic (lethargic) encephalitis (Gould) an epidemic form of encephalitis, frequently occurring with influenza, and characterized by drowsiness, apathy, muscular weakness and paralysis of the third cranial nerve.

Narcolepsy (Gould) an uncontrolled tendency to attacks of deep sleep of short duration, it has been observed in epilepsy and other affections.

The *Quarterly Cumulative Index Medicus* lists narcolepsy under disturbances of sleep.

S B Wortis and Foster Kennedy published a short review of narcolepsy last year which might be a good starting point for reading, as the bibliography is extensive. They look on narcolepsy as a symptom complex denoting an underlying neurophysiologic derangement probably of an organic (physico-chemical) nature in the region of the third ventricle and the periaqueductal regions. The review was published in the *American Journal of Psychiatry* (12:939 [March] 1933). The journal is published at 1500 Greenmount Avenue, Baltimore.

### VACCINES IN SINUS INFECTIONS

*To the Editor*—Will you please advise me in regard to the use of vaccines autogenous and otherwise in cases of two or three years' standing of maxillary sinus infections? The symptoms are simply a profuse sticky mucoid posterior nasal discharge with clouding of the sinus in the roentgenogram. The temperature reaches 99.4 F daily. Please omit name.  
MD New York

**ANSWER**—The symptoms given do not substantiate a diagnosis of a suppurative condition in the maxillary sinuses. The diagnosis of maxillary sinusitis is based first of all on a careful examination (usually after shrinking of the nose), which reveals the presence of pus in the middle meatus. Roentgen observations and the results of transillumination are taken into consideration. The offending sinus is washed out with an irrigating solution and the presence of pus in the cavity substantiated. The maxillary sinus may still, under these circumstances, be acting only as a reservoir for an infection in the frontal and ethmoid sinuses, and only after disease in these has been ruled out can one say that the maxillary sinus is the sole offender. From time to time one sees persons in whom roentgen examination shows the so-called clouding of the sinus. This may not mean an active infection. It may be the evidence of a thickened lining membrane due to disease in the far past, and which is now, to all intents and purposes, clinically healed. Furthermore, such clouding of the maxillary sinuses is seen in the roentgenogram in the absence of suppurative disease and may then be due to an allergic or other state.

Postnasal discharge is frequently seen in certain people and in certain climates and does not necessarily bear any relationship to suppurative sinusitis. Admitting in the case cited that

there is present a bilateral maxillary sinusitis as evidenced by the roentgen examination and a postnasal discharge, the proper treatment, at first, would be to irrigate the sinuses for a time to see whether this alone might not ameliorate the condition or cause it to disappear. It is assumed that there are no marked anatomic or pathologic conditions present, such as polyps or a badly deviated septum.

In the event that properly conducted and repeated lavage does not result in the improvement desired, some form of operation should be considered, for it is not likely that a suppurative condition present for three years would yield to vaccines, autogenous or otherwise. The use of vaccines in sinusitis is debatable. Many specialists of high quality have no faith in them. It is quite possible that vaccines will be found helpful in a small percentage of acute cases, and some seem to think that their use is occasionally valuable in preventing acute recurrences.

Chronic sinusitis of three years' standing would not often, in itself, produce a temperature reaching 99.4 F daily. It would be advisable to search for some other cause for the elevation of temperature.

### DIAGNOSIS AND TREATMENT OF PURPURA

*To the Editor*—I have under my care a boy aged 6 years who gives the following history: About one and a half years ago he had a gastro-intestinal upset with pains and cramps in the abdomen. Appendicitis was suspected but he seemed to have complete recovery without operative treatment. About six months ago while on a vacation there was a recurrence of the gastro-intestinal upset with severe cramps, pain and vomiting. He was observed by nine physicians and the consensus was appendicitis. They were about to operate when the symptoms subsided so suddenly that this plan was abandoned. About a week ago the child suffered another acute attack with severe abdominal pain, nausea and vomiting. He vomited blood before I arrived. On my arrival about two hours after the beginning of the attack all the intestinal symptoms had disappeared. Large hemorrhagic spots covered the arms, the legs and back. The mucous membrane of the mouth and tongue also showed hemorrhagic areas which were still oozing. My diagnosis was purpura hemorrhagica. I should like to know the different types of treatment and also the prognosis in such a case. Kindly omit name.  
MD, New York

**ANSWER**—Before discussing the various types of treatment and prognosis, it may be well to say a few words about the diagnosis in this case. The term purpura hemorrhagica is usually applied to the thrombopenic form of purpura, or Welhof's disease. The history and physical examination suggest the symptomatic form, often called Henoch's purpura. While at present the clinical classification of purpura is most unsatisfactory, the current ideas can be grouped under two schools of thought. There are those who would place all purpuras in one group with the idea that the various clinical forms may be considered variants of the same hemorrhagic diathesis. Others make a strict differentiation on the basis of whether the platelets are reduced or not and group the cases with purpura under two main divisions, the thrombopenic forms and the symptomatic varieties.

The question of classification is not an altogether academic one, as it involves a conception on which treatment and prognosis are based. The controversy is whether the vessel permeability is a primary factor underlying all types of purpura or whether it is the basic mechanism in the symptomatic form only. In the thrombopenic group a disturbance of the intravascular clotting mechanism is also present, which contributes to more severe and chronic hemorrhage. Whatever conception is chosen, it is established that purpura does occur without a reduction of platelets but that the symptom is more constant and severe when the platelets are reduced below the level of 50,000. Hence the treatment and prognosis are both influenced to some extent, depending on the reduction of platelets to a critical level. As a rule thrombopenia is not present in cases presenting abdominal symptoms and purpura, although there are exceptions. The clinical picture is often like the case cited and may simulate an acute appendicitis or intussusception. While such cases should not be confused with these clinical conditions and needless operation be done, it is well to bear in mind that surgical intervention is sometimes indicated in the true Henoch type of purpura. Actual intussusception has been known to occur if the hemorrhage is of sufficient amount to produce a large amount of blood in the wall of the intestine. Under this circumstance the part of bowel affected becomes motionless and the increased peristalsis in the adjacent part of the bowel may drive it into the paralyzed part, producing a true intussusception. Other cases are on record in which operation revealed a true hemorrhagic appendix in Henoch's purpura. Therefore while conservative treatment should usually be chosen in cases of this type the possibilities should be borne

in mind Apparently the pathogenesis in Henoch's type of purpura is an alteration in capillary permeability, which may manifest itself clinically in all stages from a transudative process to a truly hemorrhagic manifestation

The etiologic factors responsible for this derangement in the capillary mechanism may be (1) food allergy, (2) anaphylatoxin associated with a bacterial protein, or (3) histamine-like substances derived from the proteins in the gastro-intestinal tract The action of these substances may be directly on the capillary endothelium or on the vasomotor mechanism According to this etiologic conception, treatment may be suggested along several lines, but it is well to remember that a large number of these cases undergo spontaneous remissions Calcium preparations, by mouth or intramuscularly, are the most popular symptomatic remedies However, in every case of Henoch's purpura the question of allergy and infection should be seriously considered and appropriately treated if present If the attacks of purpura are repeated often, the patient may require treatment for anemia caused by chronic loss of blood In cases in which thrombopenia is definite and persistent, blood transfusion is indicated The prognosis is usually good if there are no acute abdominal and renal complications

#### TOXICITY OF CHLORPICRINE GAS

To the Editor—I would like information regarding the toxicity of chlorpicrine gas It is manufactured by the Innis Speiden Company New York It is used as a weevil exterminator in a grain elevator I have a patient who has had two attacks of pyelitis recently apparently caused by this gas Please omit name

M D Ohio

ANSWER—Chlorpicrine is trichloromethane or nitrochloroform, having the formula  $\text{CCl}_3\text{NO}$  This substance has been much used as a war gas of the lachrymatory variety Exposure promptly leads to severe frontal headache Animal experiments carried out by the Chemical Warfare Service of this country failed to reveal consistent evidences of gross pathologic changes resulting from the action of chlorpicrine The toxicity of chloroform (trichloromethane) is well known in relation to anesthesia As an industrial agent trichloromethane is rated as possessing a toxicity at least double that of carbon tetrachloride, which is regarded as a highly dangerous industrial substance The introduction of the "nitro" radical into the chemical structure is believed definitely to enhance the toxicity This general group of chemicals may be credited with the capacity of producing renal lesions and damage to the respiratory and gastrointestinal tracts and the liver If the two attacks of pyelitis mentioned in the query are the sole manifestations of the action of chlorpicrine, a cause and effect relationship may be doubted Contrariwise, if various other evidences of damage to other body organs may be established, a possible cause of the pyelitis may reside in the chlorpicrine Under any circumstances, exposure to any considerable concentration of chlorpicrine is to be associated with apprehension

#### DERMATITIS AND BRUCELLA ABORTUS

To the Editor—I am wondering whether the following condition is common About three weeks ago a farmer, aged 39 came to me complaining of an eruption on both arms The lesions were found to be papulovesicular in character, surrounded by a moderate amount of edema and erythema The lesions were bilateral in distribution and were seated over the entire arm from the wrist to about 3 inches above the elbow There was no history of allergic tendencies or of the previous occurrence of the present condition Two days before he had tried to deliver manually an apparently healthy cow which had been in labor for only ten hours Both arms were inserted to about the level of the lesions on the upper arms I advised hot moist dressings and an anti pruritic for the burning and itching Several days ago he came in again My directions had been only partially carried out He stated that each lesion eventually became like a boil and had to be opened and drained before healing At that time the lesions were practically all healed but presented the picture of a healed furuncle What was the cause or nature of the condition? Is this condition common? What is the best line of treatment? It took two weeks to clear up under my care Please omit name

M D, Colorado

ANSWER—Dermatitis of the arms is common in veterinarians engaged in the treatment of cows infected with *Brucella abortus* This is a common disease of cattle Although the cow treated by the patient in this case seemed healthy, it is known that many cows are carriers of this infection, showing no evidence of disease

The dermatitis is due to sensitization of the skin to the infected vaginal secretion, not an infection of the human skin The subject was discussed by L F Weber (*Brucella Dermatitis*, *Arch Dermat & Syph* 26 422 [Sept.] 1932) A query on this subject was answered in *THE JOURNAL*, January 6, page 69 As suggested in the answer mentioned, long rubber

gloves should be worn in all obstetric work by one sensitized to this form of irritation After careful removal of the gloves, to avoid contact with the contaminated exterior, a thorough washing with soap and hot water is indicated

The treatment given the case in question was proper, except that cool wet dressings are usually more soothing to a dermatitis than hot applications Furuncles are apt to occur after any such dermatitis, because the inflammation has lessened the skin resistance The doctor is to be congratulated on having cleared it up in two weeks That was a prompt result Cool wet dressings of aluminum acetate solution diluted with fifteen parts of cool boiled water or a saturated solution of boric acid, followed by calamine lotion containing 0.5 per cent of phenol and of glycerin is a good plan of treatment The cool wet dressings should be applied for half an hour at a time, several times a day

#### AMAUROTIC FAMILY IDIOCY

To the Editor—Kindly tell me the most prominent symptoms of amaurotic family idiocy in a boy of 2 years What are the causative factors? Could smoking or drinking by the mother during gestation produce such an effect? Kindly omit name

M D, Illinois

ANSWER—Amaurotic family idiocy of the infantile type is also known as Tay-Sachs disease It usually begins in the first six months of life The first symptoms noted are listlessness, inactivity, and indifference of the infant to its surroundings Until the time when these symptoms are first manifested, the infant has developed in a normal manner, and with the onset of the disease a gradual retardation in development occurs and the infant begins to lose ability to perform voluntary activity, such as sitting up and rolling over, which it formerly possessed The baby becomes apathetic, does not smile, and gradually fails to respond to the spoken word as it formerly did The muscles of the limbs become flaccid, and the infant loses the ability to sit upright and to hold its head up This flaccid state gradually changes to a spastic condition

With these changes in the general condition, visual changes occur The infant loses the power to notice objects held before its eyes, does not follow light as formerly, and finally may become totally blind On the other hand, the acoustic sense becomes highly acute The slightest noise will prove startling As the infant lies quietly in bed or on the examining table, a sudden sound, such as the closing of a door or the dropping of a metallic instrument on the floor, will cause it to start violently and jump This manifestation has been termed hyperacusis As the condition progresses, this starting at noises may finally be the cause of the convulsions noted in such infants These may be tonic or clonic and last for a period of several minutes

The infant gradually becomes emaciated with wasted and paralyzed musculature, loses its ability to suck and swallow, and finally dies of inanition The duration of the disease is from one and a half to two years after the occurrence of the first symptoms

The reflexes are usually exaggerated and a positive Babinski sign may often be elicited The pupillary reflex may be sluggish and the optic disk may show some atrophy The characteristic eye sign described by Warren Tay will be found in an examination of the fundi, where a cherry red spot surrounded by a white patch is noted in the region of the macula in each eye

The symptoms already noted, gradually increasing weakness and apathy, the hyperacusis and convulsions, with inanition, culminating in idiocy, together with the loss of vision, optic atrophy and pathognomonic cherry red spot of the macula, should make the diagnosis unmistakable

The disease is supposed to occur exclusively in infants of Jewish parentage of Russian or Polish origin This racial occurrence is the only definite etiologic factor known for the disease and even this is not certain, as its occurrence has been noted in infants of other races

Syphilis, alcoholism, infection, nicotine poisoning or tuberculosis seem to play no part in the cause The outcome seems to be invariably fatal

In recent years, amaurotic family idiocy has been linked with diseases of lipid metabolism, such as lipid histiocytosis, or Niemann-Pick disease Some writers have also included Gaucher's disease and essential xanthomatosis in this group All these conditions are disturbances of lipid metabolism, but sufficient evidence has not yet made it possible to group them together on a common etiologic basis

A late infantile type of amaurotic family idiocy is said to begin at the age of 4 or 6 and take a course somewhat similar to the infantile type without the macular change

## DESENSITIZATION TO MILK ALLERGY IN A CHILD

To the Editor—A child aged 3, suffers from asthma due to an allergic response to milk as shown by a skin reaction and by freedom from attacks while on a milk free diet with return on the reintroduction of milk. Is it possible to prepare milk to be used for desensitization, in the office with ordinary equipment and from ordinary milk? If so please give particulars. I should like to avoid the expense of the usual commercial desensitization set if this can be done without danger to the patient. Please omit name and initials.

M D, Mame

ANSWER—The hypodermic desensitization or injection treatment for foods is seldom necessary, since it can be usually accomplished more successfully and with much less expense at home, by daily ingestion of that food. In instances in which home cooperation is not of the best, such a procedure might be advisable. Hypodermic desensitization to foods has its greatest usefulness in those instances in which the contact with the food material is by inhalation rather than by ingestion, as, for example, in bakers sensitive to wheat.

The procedure of choice in oral desensitization is to administer orally small amounts of the guilty food. Daily doses of the food are taken. The first portions are very small. In the case of milk, one drop of milk in a glass of water would be sufficient to start with, then two drops, and so on. The rate of increase varies with the degree of sensitiveness of the individual. By diligent application it is often possible to attain a practical tolerance in from six to twelve months, that is, by the end of the period the patient may be able to take a glass of milk without the production of symptoms.

It would be rather difficult to prepare milk for hypodermic administration in the office, to compare with a commercial desensitization set. First of all, the cream must be removed. Then the casein, precipitated by the addition of rennin must be filtered out through a Berkefeld filter. The filtrate must then be sterilized by boiling and diluted with phenolized salt solution (physiologic solution of sodium chloride to which 0.4 per cent phenol has been added) into solution of 1:10,000, 1:1,000, 1:500 and 1:100. These liquid extracts should be kept cool, preferably in the refrigerator. Warmth and high dilutions tend to cause rapid decrease in the potency. The office preparations of these allergens by one not experienced at such work would be somewhat risky.

## TREATMENT OF WARTS ON FACE

To the Editor—A Negro aged 40, for the past six months has had a wartlike eruption on the face. The lesions are typically filiform and wartlike in character, millet seed in size, dry, and uniformly distributed over the beard area of the face and chin. There is no itching, no exudation, no ulceration and no evidence of inflammation. The patient has a positive history for syphilis with treatment fifteen years ago. The Wassermann reaction at the present time is negative. He presents no clinical evidence of syphilis. What is your opinion as to the diagnosis, prognosis and therapy in this case? Please omit address.

M D, New York

ANSWER—Two possibilities are suggested. If the lesions are soft, they are pendulous soft fibromas, often seen but seldom so numerous, and easily eradicated by clipping them close to the skin surface and touching the spot with a small cautery point at red heat.

If the little tumors are horny, there should be many still smaller flat topped ones among the filiform ones. The diagnosis of common verruca seems highly probable. In this case shaving should be interdicted, for it will propagate warts faster than any treatment can eradicate them. An antiseptic lotion, such as corrosive mercuric chloride 1:1,000 in 50 per cent alcohol, should be used after clipping the beard with scissors, with care to avoid the warts.

Touching each wart several times a day with Vlemnick's solution, liquor calcis sulphuratae, or 10 per cent salicylic acid in alcohol may in time cure them.

They can be curetted, each base dried by pressure with a sponge saturated with the antiseptic solution mentioned, preferably in this case with alcohol, then each base touched with phenol, tincture of iodine or trichloroacetic acid. Each wart can be desiccated with the high frequency current with care to avoid scarring. G. C. Andrews (Diseases of the Skin, Philadelphia and London, W. B. Saunders Company, 1930, p. 877) recommends removal of the burned tissue after desiccation and half an erythema dose (150 roentgens) of unfiltered roentgen rays to the area.

Without the desiccation roentgen rays in moderate dosage—less than necessary to produce erythema—will sometimes cure them.

Mercury compounds by mouth or intramuscular injection, bismuth compounds intramuscularly, and various forms of arspenamine have all been used for the treatment of multiple warts with more or less success.

The psychic treatment of warts has been attracting much attention of late years, fostered chiefly by Bloch, who succeeded in curing a large percentage of cases by suggestion. A recent contribution to this time honored method is that of H. V. Allington (Sulpharsphenamine in the Treatment of Warts, *Arch. Dermat. & Syph.* 29:687 [May] 1934), who tested the value of sulpharsphenamine in the treatment of warts—a subject of controversy for years. Allington treated a series of fifty-five cases of warts with sulpharsphenamine injected intramuscularly, and a parallel control series of sixty-one with distilled water colored to match the sulpharsphenamine solution and injected in the same way. The injections of water cured nearly as large a percentage of cases as the sulpharsphenamine.

Another interesting contribution along this line is the work of F. E. Cormia (Autolysate Therapy for Verruca Vulgaris, *Arch. Dermat. & Syph.* 30:44 [July] 1934), who tested the method of Biberstein, who successfully treated warts with an autolysate of each individual's own warts. Cormia, in trying this method, intentionally discouraged his patients to reduce the probability of obtaining a cure by suggestion and in twelve cases treated succeeded in curing only two.

Just how much treatment of warts is chemotherapy, electrotherapy, or actinotherapy and how much psychotherapy is difficult to say, but it is evident that much more of it than the physician suspects is psychotherapy.

## ALOPECIA AREATA

To the Editor—A woman aged 30, has been suffering for several years from extreme loss of hair. At times her hair almost completely comes out. Then a new growth appears. At present there is a bald area about 6 inches in circumference. She has no children and the past history is negative in regard to this disease. She has been treated by at least a half dozen skin specialists with no results whatever. Naturally she is greatly alarmed in view of the fact that no doctor as yet has been able to prescribe or give her any relief. I have given her arspenamine treated the condition locally with various prescriptions, tried thyroid extract and pituitary extract, and administered various tonics internally. On examination the heart, lungs, kidneys, blood pressure and blood are all normal. If possible, could you suggest from the symptoms anything that would be wise to give her? Kindly omit name.

M D, Georgia

ANSWER—The patient is suffering from alopecia areata. The history of recurring attacks of loss of hair is quite characteristic of this disease, especially the fact that at present there is one bald area 6 inches in circumference. The exact cause of alopecia areata is not known. Certain cases are due to severe nervous shock or psychic disturbance. In some instances the disease seems to be linked up with metabolic disturbances or with foci of infection. Many times the physician is unable to find any explanation for the trouble. Despite the comment as to lack of results from treatment by skin specialists, the best advice is reference to a specialist in this particular line of work for even the men best versed in dermatology may have difficulty in coping with such a trouble. In the way of treatment one should, of course, endeavor to remove any possible factor of causation, for example, impacted or infected teeth or infected tonsils. Local treatment consists in the use of stimulating measures, for example, the use of stronger ammonia water rubbed well into the areas twice a day, or the use of a 1 per cent pilocarpine lotion made up in equal parts of rose water and perfumed spirit, N. F. Quartz lamp therapy up to the point of erythema doses is also of value in this condition. In a case in which there is a history of frequent recurrences of the disease, the prognosis is guarded.

## DIFFERENTIAL DIAGNOSIS OF COLDNESS OF FEET WITH SORENESS

To the Editor—A man aged 26, weighing 145 pounds (66 Kg) complains of soreness and aching in the soles of the feet, up the calves of the legs and across the back. His feet are almost always cold, winter and summer. The blood pressure is normal. The Wassermann test is negative. It affects him mostly when he is standing and the feet are cold from the ankles down. There is no discoloration of the toes after nating hyperemia or anemia. He feels tired. His feet sweat a good deal. There is no pain in his legs at night.

JOHN L. HEALY, M D, Newport, R. I.

ANSWER—The symptoms suggest the following possible diagnoses:

1. Some infectious process in the nerves, muscles or joints, such as early arthritis, or fibrositis secondary to some infection. A roentgenogram of the feet should be made for possible demonstration of arthritic changes in the small bones. Tenderness along the nerve trunks, or local tenderness in the muscles, should be sought. The treatment for this would be

baking and massage, salicylates internally, and removal of any foci of infection. Autogenous vaccine might be tried.

2 Structural defects in the feet. Occasionally this type of pain, bilaterally, is seen with marked grades of flatfoot. Therapeutic tests can be carried out by placing a transverse bar on the sole of the shoe. If no relief is obtained from this treatment, the condition is not present.

3 One of the various neuroses that accompany conditions of general fatigue, which express themselves in the extremities. The treatment of these states of local fatigue is based on measures to improve the general health, such as vacations and relief from environmental strains. Many of these patients are constitutionally inadequate. The diagnosis should be made only after careful examination and absence of organic changes.

4 A condition, observed in young men with cold clammy feet associated with pain on standing, which for want of a better term can be called "vasospastic painful feet." This condition, however, has never been described as a clinical entity. Usually the distress is relieved when the extremities have been warm for a time. A diagnostic test can be made by placing the feet in warm water, or under a radiant heater, to see whether any relief is obtained. This condition may overlap a little with that described first, for the pain probably has a twofold basis, an infectious process, such as early arthritis and intermittent ischemia of the tissues. The description of the complaint suggests this diagnosis. The injection of foreign protein intravenously (small doses of Lederle's triple typhoid vaccine in doses of from 5 to 10 million every three or four days) sufficient to produce one or two degrees of fever may give considerable relief. In addition, physical therapy and contrast baths may help.

These provisional diagnoses are made on the assumption that pulsations in the lower extremities are normal and that there is no gross neurologic condition present that could cause distress in the extremities.

#### REDUCTION OF LOCAL OBESITY

*To the Editor*—A patient of mine, an unmarried woman aged 26, presents as a chief complaint extreme obesity of the legs from the knees to the ankles. Her past history is negative; she never had lymphangitis or phlebitis. Her general health is good and the rest of the body has normal proportions. She has had these very fat legs ever since she can remember, say as a child of 7 or 8, but they became more conspicuous as she grew up and are very embarrassing to her. Is there anything that can be done about this disfiguring localized obesity? Please omit name.

M D, New York

*ANSWER*—The reduction of local accumulations of fat is a difficult and uncertain matter. General weight reduction accompanied by vigorous exercise of the affected parts is sometimes successful. Dancing and rope skipping would be the exercises of choice in this case. A brisk rubdown with massage of the affected parts after exercise periods, might also help. If the patient is not overweight the reduction diet should be intermittent so as not to cause too much general weight loss. The exercises, however, should be maintained indefinitely, since there appears to be an increased tendency for the deposition of fat around well developed muscles, once the exercise of those muscles ceases.

#### HEARING DEVICES IN OTOSCLEROSIS

*To the Editor*—I have under my care a woman single aged 20. Ten years ago she noticed that she was having difficulty in hearing. At that time her physician advised removal of tonsils and adenoids which was done by a competent specialist. The deafness has progressively grown worse. She also has developed a constant roaring and at times thumping in the entire head. Politzerization of the tubes has not improved either the deafness or the tinnitus. Physical examination is entirely negative. Aural examination is likewise negative. The patient can hear through bone conduction. All other ear tests are negative. Blood and urine examinations are negative. There is no history of scarlet fever or other infectious diseases and the patient has not taken any medicines. Her habits are normal in all respects. Could you advise me what can be tried to help this young woman? She refuses to use any of the standard appliances for the deaf or hard of hearing because they can be seen. Is there any apparatus that can be worn without detection? If you can suggest anything I would greatly appreciate it. Please omit name.

M D, New York

*ANSWER*—So far as one may judge from the history submitted the case is probably one of otosclerosis (or spongification), as evidenced by the facts that there is no change in the drum membrane, that inflation does not improve the hearing, that the patient is a female that the disease started early in life, that there is tinnitus and that the bone conduction is good. In this condition the bone conduction is usually prolonged as compared with a normal individual when tested in the usual environment. For all cases in which there is good bone conduction,

those hearing devices which have an attachment that can be placed and held firmly against the mastoid process are of considerable assistance. Several of the electrical hearing devices now on the market have this bone conduction attachment, among them being the appliances manufactured by the Sonotone Company and the Western Electric Company. Women can easily wear this head appliance so that it is not visible, because the band that holds it in contact with the skull may be hidden under the hair.

#### HEADACHES AT MENSTRUAL PERIODS

*To the Editor*—I have a patient aged 41, who complains of severe headaches and vomiting every week end. They are always worse during the menstrual period. While having these attacks she is nervous. Her menstrual periods are regular but scanty at times and at other times normal in the amount of blood. She has a few cramps but they are not marked. She has had similar attacks before but not so often. They have been usual at every menstrual period since she started to menstruate at the age of 12 years at which time she was in bed for a week. She has two children, one 9 years of age and the other 13 months. I did not take care of her during her first pregnancy but I did during the second and she had no symptoms of headaches or vomiting during the nine months or for four months after delivery at which time they started again and have gradually become worse. What line of treatment would you recommend? Please omit name.

M D, Illinois

*ANSWER*—Headaches associated with vomiting, occurring at the menstrual period, may or may not be due to hormone disturbances. Allergic and psychogenic factors may likewise be important. The fact that the patient has attacks every week suggests also that fatigue may be a contributing cause. The regularity of exacerbations of the headache at the menstrual periods does not necessarily point to hormone unbalance as the cause, a psychogenic origin arising in the prepubertal period is more than likely. Headaches with vomiting due to allergy would not usually follow a weekly rhythm.

Treatment should first consist in psychotherapy along psychoanalytic lines. If psychoanalysis is not feasible, at least a psychologic analysis should be made to discover if possible a reason for revolt against menstruation. Perhaps a rational explanation of the physiology of reproduction given to the patient will suffice.

#### RESECTION OF NASAL SEPTUM

*To the Editor*—I would appreciate any information you can give me as to the advisability of having a resection of a deviated nasal septum in a case of chronic sinusitis. Also the consensus as to the benefits that are derived from such a procedure. Will such an operation reduce the frequency and the severity of an attack of rhinitis and sinusitis? Please omit name.

M D, Connecticut

*ANSWER*—If a deviation of the nasal septum is such as to interfere with drainage from the nasal accessory sinuses, the submucous resection is advisable. In some of these cases a sharp deviation presses the middle turbinate close to the nasal lateral wall, causing marked obstruction to drainage by way of the middle meatus. It is then best to infract the middle turbinate toward the median line and provide more space in the region of the middle meatus.

Occasionally, marked thickening of the posterior portion of the septum may interfere with drainage from the posterior ethmoidal cells, and in such case submucous resection would also be of considerable aid in facilitating drainage. Even with increased air space it is doubtful whether one may say that the straightening of the nasal septum will reduce the frequency or severity of rhinitis or sinusitis, but, when the infection of the sinus does occur the improvement of space for drainage will often aid in shortening the attack either spontaneously or as a result of treatment.

#### EPILEPSY

*To the Editor*—A man aged 36 tells me that as a baby, almost from the day he was born until he was about 8 years of age he had epileptic fits almost every day. These stopped at this age and have never recurred. He is a fine specimen of manhood of foreign birth, his nervous system is apparently all right and his physical condition excellent. To his knowledge this is not a family characteristic. He has asked me what are the chances of his children being epileptic should he marry. Is he ever likely to have this condition return? Please omit name.

M D, New York

*ANSWER*—Epileptiform seizures in infancy are most frequently due to some acquired cerebral damage and are not of the same nature as cryptogenic (idiopathic) epilepsy. It is in the latter that hereditary influences play an important part. The history given in this case suggests that the man will remain free from attacks and since the lesion was probably acquired that there is no likelihood of a condition of epilepsy being transmitted to his children.

### CREDE METHOD AND VISION

*To the Editor*—Does the use of the old Crede treatment of a baby's eyes at birth (2 per cent silver nitrate immediately neutralized by physiologic solution of sodium chloride) ever cause permanent impairment of vision? Is there such a thing as an idiosyncrasy to silver nitrate used in eyes in 2 per cent strength? At about what age does a child use his eyes for vision? At about what age are the eyes fully developed? Kindly omit name  
M D Illinois

**ANSWER**—The old Crede method of using 2 per cent (or preferably 1 per cent) silver nitrate in the eyes at birth will never cause permanent impairment of vision, provided the proper technic is followed. In the cases in which damage has been reported, either the silver solution was too strong or the neutralization was postponed too long. As far as is known, there is no idiosyncrasy to 2 per cent silver nitrate. A rather severe reaction may follow the use of a solution of that strength if there has been failure to neutralize completely all the caustic agent. A child has vision at birth, but central vision, as known to the adult eye, is absent until differentiation of the macula has taken place. This starts between the fourth and sixth weeks post partum and is usually complete by the third month. The eyes are fully developed between the eighth and tenth years of life.

### REMOVAL OF TATTOOING

*To the Editor*—I would like to have your opinion as to the therapeutic value of the following prescription for the removal of tattooing taken from Fitch's Medical Formulary. First the skin is vigorously rubbed until the outer epidermis comes off, then a paste of quicklime, just slacked, to which pulverized phosphorus (two tablespoonfuls to a pint) is added and thoroughly mixed is applied to the tattooed surface and held by a bandage which is taken off two days later. The crust is left to dry and then fall off itself in about fifteen days. A second application should be made a third is rarely necessary. Thus treated the tattooing disappears completely without the least scar.

JOHN S HATTERY M D, Mansfield Ohio

**ANSWER**—There are many methods of removing tattoo marks, some of them fairly satisfactory, others less so. The claim for any one of them that "the tattooing disappears completely without the least scar" appears to those experienced in the use of the older methods somewhat exaggerated. If this claim is warranted, all other methods are due to be forgotten.

No opinion of any method for the removal of tattooing is of value except that acquired by actual experience. In the use of any method, the area treated at any one sitting should be not over 2 cm in diameter. This is particularly true in experimental work. Most methods of removal require local anesthesia. Powdered phosphorus is red phosphorus, which is nontoxic.

### THERAPEUTICS OF GARLIC

*To the Editor*—Recently two patients, one with cholecystitis and the other with arterial hypertension, have been extolling the therapeutic virtues of garlic. The vegetable has been prescribed uncooked and in considerable quantities. Are the beneficial results attributed to its ingestion due to some vitamin or are they purely psychologic in nature? I have not seen any literature on the subject.

H B HANSON, M D, Fort Brown Texas

**ANSWER**—Externally, garlic may be used as a rubefacient. Internally it is useful as a carminative—in flatulence—and thus gives symptomatic relief to a patient with cholecystitis. Taken in liberal doses it has a tendency to dilate the blood vessels of the skin ordinarily one hour after its ingestion, an effect that lasts for several hours and may possibly be of use in arterial hypertension. Its psychic qualities—the offensive odor it imparts to the breath and the sweat—are probably the chief cause for its limited use.

### CHRONIC GONORRHEA IN WOMEN

*To the Editor*—I have fallen heir to two cases of chronic gonorrheal proctitis in young unmarried girls. Hot permanganate douches three times a day and triweekly injections of metapen into the cervix have been used. Both cases now show only pus cells in repeated smears. Am I dealing now with a secondary staphylococcal invasion? There are no cervical lesions. The discharge is mucoid and in one case absent except immediately following menstruation. What is the chance for complete cure medically? What are the prerequisites for dismissal? When may these girls marry? What about diathermy in these cases? Please omit name.

M D Ohio

**ANSWER**—From the description of these two cases it would appear to be reasonable to assume that the chances for complete cure are excellent. Before the patients are discharged as cured or before permission to marry is given the following program should be carried out. The urethra Skene's glands and Bartholin's glands should be carefully examined for the presence of pus and if present this should be examined for the

presence or absence of gonococci. After three negative slides have been obtained from each of these sources, preferably one week apart, cultures should be made on special culture mediums to demonstrate the presence or absence of gonococci. Whether a secondary invasion due to the staphylococcus is present can be determined by microscopic examination of smears. It does not appear that diathermy is indicated in these two cases.

### TOXICITY OF CARAWAY SEEDS

*To the Editor*—I have a patient, aged 28 who has the habit of eating a 10 cent box of caraway seeds each day and recently has been complaining of headaches, loss of weight and general nervousness. Will you please tell me the effect of caraway seeds on the human body provided the woman has been using this preparation for the past four years? She eats the seeds.

RAYMOND H LEU M D, New Martinsville W Va

**ANSWER**—Oil of caraway is known to produce headache, dizziness and delirium in acute poisoning, and it is not unreasonable to suppose that the symptoms complained of may have something to do with this most unusual practice. The chronic ingestion of excessive quantities of substances containing volatile oil, such as caraway seed, is likely to affect unfavorably the parenchyma of the liver and kidney. A study of the functional condition of these organs should be made in this case.

### KALA AZAR

*To the Editor*—Please advise whether it would be possible or probable for a child about 3 years of age to have a case of kala azar who had never been out of the state of Texas and had no contact with any one that could have had this disease. Would it be possible that it could be transmitted by toys after they had come through the regular channels of trade? Please omit name.

M D, Texas

**ANSWER**—In the present conception of the etiology of the disease this would be considered impossible. All evidence points to an insect vector for kala-azar, most probably a species of the sand fly *Phlebotomus*. It is inconceivable that such insects could be transported by toys. In addition, all known facts of the epidemiology of the disease are opposed to this method of transmission or to spontaneous cases occurring in the United States.

### DIFFERENTIAL DIAGNOSIS IN ARTHRITIS

*To the Editor*—I have a patient aged 37 who has a chronic arthritis of three years duration. He has taken salicylates and cinchophen without relief. At the age of 16 he had gonorrhea which cleared up promptly under treatment and has not recurred. He has a boy 8 years of age and his wife has shown no symptoms. The arthritis is a migratory one and has affected his fingers, hips, shoulders and knees. The question in my mind is whether this is an infectious arthritis or whether it might be gonorrheal. Would a complement fixation test help at this time?

FREDERICK B DEWITT M D, Onocenta N Y

**ANSWER**—This is a case of rheumatic arthritis and should be considered infectious. It might be due to the gonococcus. The complement fixation test may or may not be of value as an etiologic diagnostic agent. It is true that in many of these cases the original gonococcal infection sensitizes the patient to an infection that may occur later.

### SOLUTION OF EPHEDRINE

*To the Editor*—What is the best method of dissolving ephedrine alkaloid in light mineral oil to make a 1 per cent solution? It seems not to be readily dissolved. Should a preservative be added and if so, what? Is it true that the alkaloid is much more effective for local shrinking action than the salt? Please omit name.

M D Connecticut

**ANSWER**—One Gm of ephedrine dissolves readily in 100 cc of liquid petrolatum by the aid of water bath heat. To obtain a clear solution the ephedrine must be dry or the solution filtered through dry filter paper. Some ephedrine (base) on the American market contains water of hydration or "sensible moisture." This will not dissolve in liquid petrolatum but requires addition of other solvents or filtering out of the water.

Preservatives that do not change the nature of the substance are not known. The solution should be well protected from light and heat, and it should be prepared in small enough volume so that it will be used up in about three months.

Ephedrine salts are not soluble in liquid petrolatum, therefore they would not be available for preparing oil sprays. The aqueous solution of the salt will have a prompter but more transient effect than the oil solution of the alkaloid. Usually the latter effect is desired. There have been introduced other vasoconstrictors as Symphephrine Tartrate, Neosymphephrine and Benzadrine. The latter is volatile and may be used in a nonliquid type of inhaler (inhalator tubes).

## LEUKORRHEA IN PREGNANCY

To the Editor—I have observed quite a few cases of an irritating leukorrhea producing inguinal dermatitis and excoriations in several of my prenatal cases. This leukorrhea has not appeared until the last two months of pregnancy and there has been no evidence of any infection gonorrheal or otherwise prior to the last two months. I have talked with a number of my colleagues, who state that they are familiar with the condition but are also in the dark as to the best mode of treatment. The data that I have given are limited but is there any physiologic or etiologic explanation for this annoying condition? Since one does not ordinarily use douches the last two months of pregnancy, what would be the best mode of treatment? Please withhold name.

M D California

ANSWER—Pressure and congestion are, of course, the chief factor in predisposing to discomforting leukorrhea during the late months of pregnancy. Less well recognized, an increased sugar content in the urine and in the serum of the genital secretions at this time is also important in producing low grade vulvovaginal infection.

The carbohydrate intake of these patients should be restricted. Although local treatment of any sort is advocated with hesitancy in the late months of pregnancy, dry cleansing of the lower part of the genital canal and gentle use of astringent topical applications may be resorted to in selected cases. Aseptic technique is imperative.

## SILICA AS A HAZARD IN SOAP FACTORIES

To the Editor—Will you please let me know if the hazard of silicosis exists among workers in various soap factories?

MOSES J STONE M D Boston

ANSWER—Silicosis is a hazard in those soap factories using silica (SiO<sub>2</sub>) in the manufacture of abrasive soaps. Others may make use of silicates for abrasive purposes and the possibility of silicatosis exists. As a filler for some soaps sodium silicate is employed in liquid form. This use of a silicate is dissimilar to the employment of such others as pumice for detergent purposes. Cases of silicosis originating in soap factories are well known. It has been stated that the coexistence of silica and alkali dusts in soap plants is conducive to an accelerated form of silicosis to which the term "acute silicosis" has been applied. This accelerating or aggravating action of alkalis is not definitely proved, but in any event certain cases of silicosis among soap workers rapidly have progressed to disability and to death.

## BELCHING WITH AEROPHAGIA

To the Editor—I have a patient aged 34 a white woman who has had severe attacks of belching of almost a hiccup-like nature for the past year. They occur several times a day with no relation to meals or diet. Belladonna, alkalis and barbituric acid sedatives have no effect. Physical examination is not remarkable except for a slight systolic murmur and for staccation under the eyes. Urinalysis is negative. There is no pain and the patient sleeps well. Could you suggest the possible diagnosis and treatment? Please omit name.

M D Alabama

ANSWER—The information submitted in this question is too meager to furnish any definite idea as to the possible cause. The fact that the patient has indulged in this form of belching for years suggests that it is functional in character. However, it may be of reflex origin from some disturbance in the biliary or gastro-intestinal tract. Some form of psychotherapy might be suggested after a complete investigation has been made and the patient assured of the absence of organic trouble. One might let the patient observe in the course of the fluoroscopic examination of the stomach that she actually swallows air every time that she belches. This kind of evidence of the absence of gas formation in the stomach has at times striking suggestive therapeutic effect.

## FUNCTION OF FETAL KIDNEYS

To the Editor—In THE JOURNAL July 14 page 126 is a query regarding the fetal kidneys and their function. I should like to mention the results of a necropsy at the Greenpoint Hospital in September 1933. A new born male child presented a completely imperforate urethra. The bladder showed muscular hypertrophy and submucosal hemorrhages. Both ureters were markedly torse and showed a segmental dilatation which at some points almost resulted in stricture. Both kidneys were polycystic. The bladder contained urine and the renal cysts contained a urinous fluid. About 500 cc of fluid was free in the abdomen. There was no evidence of hepatic abnormality. There was no cardiac dilatation. It can be presumed here that fetal secretion of urine was present. With complete closure of the urethra the muscle wall of the bladder hypertrophied in a vain attempt to expel its contents and even causing submucosal hemorrhages. Back pressure could effect the dilatation and torsion of the ureters and may have been an etiologic factor in the production of bilateral polycystic kidneys. Whether hypertension was present or not is not known.

SAMUEL WALDMAN M D Brooklyn

## Book Notices

**Brucellosis A Public Health Problem** By Ward Giltner. Agricultural Experiment Station Michigan State College of Agriculture and Applied Science. Section of Bacteriology. Memoir No 1. Paper. Pp 118. East Lansing Mich 1934.

The author has successfully achieved his purpose in conducting this study, namely, to provide practitioners of human and veterinary medicine with a broad but concise statement of the present knowledge of the *Brucella* (Alcaligenes) diseases of animals and man. Due importance is also given to the problem as it relates to the owners of susceptible livestock and to those who are concerned with industries that deal in animals and animal products. The author possesses qualifications for a synthetic statement of the problem. Under his direction, workers at Michigan State College have engaged for many years in a comprehensive study of *Brucella* infections. Giltner states that brucellosis (brucelliasis) is certainly comparable in importance to bovine tuberculosis as a disease of cattle. The comparative importance of the two diseases of bovine origin is, however, directly influenced by the measures that have been taken to control the one or the other disease in cattle or otherwise to prevent their dissemination. In those states in which vigorous and successful campaigns against bovine tuberculosis have been carried out, the disease has been largely eliminated among other animals and human beings. In these areas, however, many cases of undulant fever of bovine origin have developed. *Brucella abortus* infection is most common in those countries in which there is a highly developed dairy cattle industry, it is transmitted to man by the ingestion of raw milk and its products, and by direct contacts with infected cattle. *Brucella suis* infection is confined almost exclusively to hog raising sections, it is transmitted to man by contacts, especially in hog packing plants, in the butcher shop, on the farm, or as a result of handling or eating infective pork. *Brucella melitensis* infection is most frequent in regions where the milch goat is a common source of milk and its products, man acquires the disease from the ingestion of raw milk and unpasteurized dairy products and from contact with affected goats, goat tissues or excretions. The prevention of brucel-

losis in man is essentially a problem in animal hygiene, the animal sources must be brought under control. Attempts are being made to eradicate the disease in cattle by blood testing and isolation or disposal of all reactors, disinfection of the premises and replenishing of the herd with nonreactors or by building up the herd from its own progeny. While this plan has great promise, it has been applied to an insignificantly small percentage of the dairy herds of this country. While experience with bovine tuberculosis and other diseases of cattle indicates that governmental financial aid and coercion make possible the practical eradication of cattle disease over considerable areas, Giltner does not consider it wise at this time to undertake such an extensive program with brucellosis of cattle, goats and swine. There is some evidence that preventive vaccination with Huddleson's avirulent live culture vaccine of *Brucella abortus* may be of some value as a supplement to the segregation plan. Pending the achievement of a brucellosis-free animal population or an acceptable immunizing agent, human beings must be protected from milk-borne infection by legally enforced or voluntary pasteurization of market milk and the milk to be used for dairy manufactures. An educational campaign designed to prepare producers, consumers and health enforcement officers should pave the way for protective legal measures.

One inconsistent statement is found. At one point the author says "At present there are those who would minimize the importance of consuming infective dairy products and magnify the importance of animal contacts. There is nothing to be gained by taking either stand." On another page appears this statement "At the present time there is sufficient information to indicate that Bang's organisms in milk are rarely responsible for producing undulant fever in human beings." On several other pages, convincing evidence appears that ingestion of raw milk containing *Brucella* organisms is a common source of infection. This contradiction does not detract, however, from the value of this monograph to the physician, public health worker, veterinarian or dairyman.

**Les traitements de l'hypertension artérielle** Par Maurice Roch professeur de clinique médicale à la Faculté de Genève. Paper. Price 20 francs. Pp 148. Paris Masson & Cie 1934.

This small, highly condensed monograph is one of a series on medical and surgical practice. It is clearly and concisely written and briefly covers the field designated by the title. All the more recent and important of the almost innumerable therapeutic measures in hypertensive disease are mentioned and an attempt is made to evaluate their worth. The critical discussion, however, is not as broad or as inclusive as one might wish. The plan and style are logical and simple. The work is an excellent summary of existing methods of therapy, there is perhaps a natural overemphasis of the choline derivatives and surgical sympathectomy. This is not surprising in view of the many French studies concerning these two lines of therapeutic attack. The bibliography is not voluminous but appears to be well chosen and contains more references to the American literature than is usual with work from the continent. The discussion is limited strictly to the problems and methods of therapy in hypertensive arterial disease and its commoner complications. This is unfortunate, as logical curative therapy must be based on an understanding of etiology and pathogenesis and therefore any truly complete discussion of therapy requires due emphasis of these. As a brief outline of present-day methods the volume is to be commended. It will have a definite place in the literature of hypertensive disease.

**Pathologie buccale Péri buccale et d'origine buccale** Par les Drs Rousseau Decelle et Raison. La pratique stomatologique. Publiée sous la direction du Dr Chompret et autres. Cloth. Price 85 francs. Pp 576 with 196 illustrations. Paris Masson & Cie 1933.

The text is divided into two parts. The first is concerned with diseases primary in the mouth and the second with the manifestations in the mouth of diseases of other parts of the body. It is an encyclopedic presentation of stomatology and not strictly a pathology. For example, the parasitology, etiology, pathologic anatomy, symptomatology, prognosis and treatment of actinomycosis occupy ten pages, the symptomatology alone covers four and one-half pages. Such subjects as syphilis and tuberculosis are discussed in great detail, although on

the whole most diseases are treated quite briefly. In the section on deficiency diseases some hesitation is manifested in ascribing the etiology of rickets to a deficiency of vitamin D, and Melanby is placed as an American worker. Eighty-six of the illustrations are excellent drawings and the remainder are poor to fair reproductions of photographs. In the United States this book has some value for reference purposes.

**Developmental Psychology: An Introduction to the Study of Human Behavior.** By Florence J. Goodenough, Professor, Institute of Child Welfare, University of Minnesota. The Century Psychology Series. Edited by Richard M. Lillott. Cloth. Price \$3. Pp. 619 with 81 illustrations. New York & London: D. Appleton Century Company, 1934.

One logical way to teach psychology to beginners would be by showing the development of traits, mental functions and abilities with the increase in age of an individual. The present work is an admirable attempt to do this by showing ontogenically the mental capacity of the human child, the adolescent, and the mature and senescent adult. A well selected synthesis of facts about heredity and embryology, with emphasis on the nervous system, precedes chapters dealing with the infant before speech begins and after its onset. Succeeding chapters describe in chronological order the social, emotional and other characteristics of the mental life of the child through prekindergarten, kindergarten, school child and college student ages. Daily the genetic psychologists of the country are pouring out more experimental results, so that selection of these in such a way as to show how they fit together to form living personalities is no mean task. Goodenough has done it in a way that will give the beginning student an idea of modern psychology, and the present volume will quite likely supersede the stodgy structuralistic textbooks that are still being used in many institutions. It gives a decidedly better understanding of the mechanics of behavior than earlier textbooks. To the pediatrician and pediatrician it gives for the first time concise, systematic and annotated information about the normal development of gross functions (such as color vision or introversion) to be expected at definite periods of the life cycle. To these specialists it gives also an idea of some of the more useful psychologic techniques and the aims of modern psychology. However, the chapters on mental disease and old age are inadequate and unnecessary and might well be disregarded.

**Archiv und Atlas der normalen und pathologischen Anatomie in typischen Röntgenbildern. Röntgenologische Skelettstudien an menschlichen Zwillingen und Mehrlingen. Ein Beitrag zu den Problemen der Konstitution und der Phylogenese.** Von Franz Buschke. Mit Geleitwort von H. R. Schinz. Mit Unterstützung der Stiftung für wissenschaftliche Forschung an der Universität Zürich. Fortschritte auf dem Gebiete der Röntgenstrahlen. Ergänzungsband XLVI. Herausgegeben von Prof. Dr. Grashey. Paper. Price 25 marks. Pp. 150 with 55 illustrations. Leipzig, Georg Thieme, 1934.

H. R. Schinz, professor of roentgenology in Zurich, in a prefatory word points out that the study of genetics is yet in its infancy and that an intensive study of human heredity did not begin until after the World War. He points out further that the study of twins is the most certain method for determining some of the relations between inherited and acquired characteristics.

Buschke, the author, says that the skeleton is in many respects a mirror by means of which the biologic changes in the organism can be read. The roentgen-morphologic analysis of the skeleton, especially of the growing skeleton, gives perhaps more exact information about the variations in the function of the endocrine organs than can be obtained in any other way. The author's purpose is to determine to what extent hereditary factors influence the development and individual form of the skeletal system. He presents the results of roentgenologic study of the skeleton in twenty-five pairs of identical twins, eighteen pairs of two egg twins of the same sex, seven pairs of two-egg twins of opposite sex, four sets of triplets, and one set of quadruplets. In form and structure of the skeleton there are marked concordances even to the smallest detail, in the identical twins, and corresponding discordances in the two egg twins. The discordances in the two-egg twins are less marked, however, than in two persons of the same age and sex who are not related. The order of ossification is in general constant. A distinction must be noted between centers which ossify in regular order and those which do not ossify in the same order in all persons. The latter centers usually ossify in the same

order in siblings, but there may be marked discordances, even in the identical twins. The time of ossification shows marked similarity in identical twins, dissimilarity in the two egg twins. Special peculiarities of ossification appear to be concordant in identical twins and discordant in two egg twins, though the author admits that the material is too meager for final conclusions.

The conclusions drawn from the investigation are discussed, and the results placed, as far as possible, in their proper relation to genetics. The possibility of evaluating the results with regard to the problem of evolution is indicated. The observations are clearly presented in fifty detailed tables accompanied by numerous roentgenograms. There are also six summary tables. Table 1 gives an outline of the whole investigation, table 2 a summary of the observations in identical twins, table 3 a summary of the observations in two-egg twins, tables 4, 5 and 6 indicate the order of ossification of the bones of the hand, elbow and foot in the various cases. Before discussing his own work, the author discusses briefly what is known about the biology of twins and the literature about the influence of heredity and environment on the morphogenesis of the skeleton. He also gives an excellent though brief bibliography on heredity, research in twins and multiplets, and bone development.

**Researches on Tropical Typhus. A Study of the Bacteriology, Serology and Epidemiology of the Disease.** By Ludwik Anigstein, M.D., Ph.D., Parasitologist to the State Institute of Hygiene, Warsaw, Poland. Studies from the Institute for Medical Research, Federated Malay States, No. 22. Cloth. Pp. 186 with illustrations. Kuala Lumpur, Kyle Palmer & Company, Ltd., 1933.

The typhus-like disease first described under the name tropical typhus by Fletcher and Lesslar (*Bull. Inst. M. Res. F. M. S.* 1925, No. 2) has been the subject of the extensive investigations reported here in monographic form. Special attention has been paid to the symptomatology and Weil-Felix reaction in ninety cases of tropical typhus from the Oil Palm Estate (Selangor Province, Malaya), to the study of the experimental disease in guinea-pigs, rabbits and rats, to the bacteriologic studies and to the epidemiology of the disease, with particular reference to the rural and urban types.

The incubation period varied from eleven to twenty-one days. The disease was characterized by a rather sharp onset, a fever reaching 102 F. on the third or fourth day and increasing to 104 F. the next few days, followed by rapid defervescence, and inconstant rash which frequently attacked the face, symptoms of dysfunction of the central nervous system, enlargement of the lymphatic glands, a lymphocytosis of from 40 to 60 per cent with the absence of eosinophilic cells, and a death rate of about 14 per cent. The disease appeared to be particularly more virulent for Europeans than for natives.

Weil-Felix reaction carried out with the two Proteus organisms OX<sub>19</sub> and OXK showed that the reaction with OX<sub>19</sub> was just as specific for the urban (W) type of tropical typhus as for typhus exanthematicus, while a similar part was played by reactions with OXK for the rural (K or scrub) type of the disease. Patients' serum (of W type) when absorbed with living suspensions of the W strain had both the H and O agglutinins removed by the absorption. As regards thermolability, the behavior of the agglutinins in tropical typhus patients may be compared, in general, with that of typhus fever.

Guinea-pigs were found to have a marked resistance to experimental infection with tropical typhus, only 11 per cent showing a febrile reaction. A redness and swelling of the scrotum was noticed in 6 per cent of the guinea-pigs inoculated. Necropsies of the animals that reacted to inoculation disclosed normal or moderately enlarged spleens, enlarged suprarenal glands, hemorrhagic foci in the lungs, and congested meninges. Hemorrhagic gelatinous exudates in the polar fat of the testes, often with marked injection of the tunica vaginalis, were found in most of the male animals. Large numbers of micro-organisms corresponding to different phases of the rickettsiae that have been described from guinea pigs with infections with Mexican typhus were observed in the smears from the tunica vaginalis. Thirty-five per cent of the rats inoculated were found to be susceptible and X<sub>19</sub> agglutinins were formed more readily in them than in the rabbit. The Weil-Felix reaction in rats and rabbits was found to be a reliable indicator of a specific infection.

Cultures were made from the blood of human cases on diluted Hottinger broth. After one week's incubation subcultures were made on a blood ascitic-agar medium, even though no visible growth could be seen on the primary cultures. A total of seventy-six strains of organisms were thus obtained from the blood and infected tissues of human patients and of infected laboratory animals and also from lice fed on patients. The organisms were highly pleomorphic, ranging from the classic rickettsial form to fusiform and "diphtheroid" rods and coccobacilli with bipolar staining. All were gram negative. Biochemically these strains fell into three groups, one of which contained strains showing the characteristics of the B proteus X group. Although most of the strains showed no serologic relationships to B proteus, they produced a positive Weil-Felix reaction in inoculated animals. Twelve of the strains, however, were serologically related to B proteus X. The virulence of the cultures for laboratory animals was highly variable in degree, the more virulent strains producing symptoms and pathologic changes similar to those produced by the original virus. These more virulent strains consisted usually of minute coccoid forms resembling rickettsiae. Micro organisms of this type were also found to develop in lice fed on tropical typhus patients and when inoculated into a rat they produced a positive Weil-Felix reaction to the XK strain. The transmission is not thought, however, to be effected through body or head lice.

The finding of a positive Weil-Felix reaction in 10 per cent of the wild rats indicated that they serve as animal reservoirs of scrub typhus. Since *Trombicula deliensis* is known to be a vector of tsutsugamushi in Japan, and since these mites were found to be common on rats in Malaya, it seems quite probable that some *Trombicula* mite may serve as the vector of scrub (or the rural type of tropical) typhus. The author inclines toward the belief that, in spite of the epidemiologic and serologic differences between the K and W types of the disease, the causative organism is probably the same species in all cases, the differences possibly being explicable because of different vectors.

Promising results were obtained with a mixed prophylactic vaccine prepared from formalized cultures that had been isolated from infected rats.

*Die Tasmassage Ihre Anwendung und Wirkungswelse bei den Weichgelenkrheumatismen* Von Dr. Walter Ruhmann Spezialarzt für Innere Krankheiten und Nervenleiden Berlin. Paper. Price 1.20 marks. Pp. 30 with 10 illustrations. Leipzig: Fischers medizinische Buchhandlung 1934.

Soft tissue rheumatism manifests itself in localized hardening of muscles or skin mainly. It may also be perineural and periarticular. Such hardenings can be found by the palpating finger tip on proper training and can often be influenced by proper local massage.

Increased blood supply and influence on tissue metabolism are invoked to explain, somewhat verbosely, the good influence on pain and the solution of the hardening when this occurs.

*Psychology and Psychotherapy* By William Brown D.M. D.Sc. F.R.C.P. Wilde Reader in Mental Philosophy in the University of Oxford. Third edition. Cloth. Price \$4.75. Pp. 252 with illustrations. Baltimore: William Wood & Company 1934.

A writer with the equipment with which Dr. Brown is endowed (for he is author of at least one fine monograph on psychology and is trained as a physician) should be expected to make a real contribution to the literature of psychotherapy. Before stating that he does, one must point out that the present work is uneven in quality, and that the chapters on peace and war and on psychical research are irrelevant. Nevertheless, a modern book in which all the various schools of psychotherapy are summarized and their applications shown has been badly needed. In this volume are discussed the underlying theories of psychoanalysis and hypnosis and their techniques. The therapeutic uses of personal influence and faith therapy are seldom discussed so that their inclusion adds to the value of this book. There is a section on juvenile delinquency which expresses a very different opinion from that generally held in this country, for the role of the parent is ignored. Adlerian psychology is not emphasized. Case histories are included, chiefly in the chapter on war neuroses. All in all one must admit that the

book is a step in the right direction, but its contents are too poorly organized for a real textbook on psychotherapeutics. For those primarily interested in this field it does offer stimulation.

*Investigations into the Cause of Mental Deficiency* By H. O. Wildenskov M.D. Medical Superintendent of the Keller Institution for Mental Defectives Brejning Denmark. (Translation from Danish by Hans Andersen.) Paper. Pp. 113. Copenhagen: Levin & Munksgaard London: Oxford University Press 1934.

This is a study of fifty propositions from the Keller institution for the purpose of determining whether the type of material used in studies of the feeble-minded has any bearing on the results. The author believes that higher grades of deficiency are more likely to be of hereditary origin than lower, so that studies made on defectives in which the subjects cover the whole range will give conflicting results. He reviews the literature covering the hereditary phases of the problem and cites various cases of his own of acquired oligophrenia. The study compares a high grade with a low grade group of defectives in regard to siblings and other relatives. Wildenskov concludes that there is a difference in the results of his observations in two groups significant enough so as to justify future studies on the subject of mental deficiency based on groups that are unified as to intelligence levels. The subjects of the present study, however, are insufficient in number and he does not show the range of intelligence within his group—two deficiencies that make the conclusion questionable. A good bibliography is appended.

## Medicolegal

**Privileged Communications Implied Waiver of Privilege**—In December 1928, before issuing four policies providing certain benefits in the event of disability, the defendant insurance company required the plaintiff to undergo a physical examination. During that examination he, in answer to a question, stated that he had never consulted a physician for or suffered from any ailment of the lungs. Some three and one-half years later the plaintiff sued the insurance company, to recover disability benefits, alleging that he was disabled by pulmonary tuberculosis. The company, in defending, claimed that the plaintiff had answered falsely the question noted above, propounded to him during the medical examination, in that he previously had had tuberculosis and had undergone medical treatment for it. At the trial, a physician, who had examined the plaintiff for the first time on the day of the trial, testified on his behalf that he was then suffering from moderately advanced active pulmonary tuberculosis which in the opinion of the witness, had existed since Jan. 1, 1932 seven months before the trial. Two physicians, called by the insurance company, each testified that prior to the date of plaintiff's examination for insurance he had attended the plaintiff in a professional capacity on several occasions and that on those occasions the plaintiff was sick, but neither of these physicians was permitted to state the ailment from which the plaintiff was then suffering. Judgment was given for the plaintiff, and the defendant appealed to the Court of Appeals of New York.

At common law said the Court of Appeals, a physician could be required on a trial to disclose information which he acquired in attending and treating a patient. A statute, however, changes this rule in the state of New York, where a physician is not allowed to disclose any information which he has acquired in attending a patient in a professional capacity and which was necessary to enable him to act in that capacity, unless the patient personally, in open court waives the privilege of secrecy. The purpose of this statute is to protect the relationship of physician and patient by preventing physicians from disclosing information that might result in humiliation, embarrassment or disgrace to patients. The question here is whether the plaintiff, by calling a physician and thereby disclosing the fact that he was suffering from tuberculosis at the time of the trial, waived his privilege of non-disclosure, so that the testimony of physicians who had treated him was admissible on behalf of the insurer to show that he was suffering from the same disease prior to his examination for insurance.

In *Capron v Douglass*, 193 N Y 11, 85 N E 827, the plaintiff testified as to his physical condition and without objection permitted a physician who had operated on him to describe what he found during that operation. When the defendant called a physician who had assisted at the operation, his testimony was excluded as privileged. On appeal, however, the Court of Appeals of New York held that if the testimony of one physician is received without objection, the privilege is waived and the testimony of another physician, who was present and assisted in an operation, when offered by the opposing party, is competent and should be received. The court did not restrict its decision to the facts of that case but expressly stated that when a plaintiff, by testimony given by others with his knowledge and consent, has exposed his physical condition to the public, the door is open for the defendant to offer the testimony of physicians on that subject. In this case, when the plaintiff called a physician to testify that he had been suffering from tuberculosis for seven months he exposed his condition to the public and disclosed the secret which the statute was enacted to protect. By his own act he removed the prohibition of the statute and waived on the trial the protection that it afforded him.

The plaintiff urged that even if the testimony of the physicians called by the defendant, as to the plaintiff's physical condition during the seven months preceding the trial was admissible, testimony by them as to his condition more than three years before the trial, when the application for insurance was signed, was not admissible. Such a contention said the court, overlooks or ignores the purpose of the statute. There would be no more humiliation, mortification or disgrace in having the fact disclosed that the plaintiff had pulmonary tuberculosis more than three years and seven months before the trial than in the fact that he had that disease for seven months before the trial. If his condition could not be shown as it existed three years before the trial, could it be shown as it existed three months or three weeks before? The disease is a progressive one. The plaintiff may or may not have suffered from it when he signed the application. That was the issue in the case, and the insurance company was entitled to have the testimony of the physicians who had examined and treated the plaintiff before the application was signed received in evidence.

The judgment of the lower court in favor of the plaintiff was reversed and a new trial granted—*Steinberg v New York Life Ins Co* (N Y), 188 N E 152.

**Liability of Druggist for Mistake in Compounding Prescription**—A physician prescribed for the plaintiff a 1 per cent solution of gentian violet, the written prescription directing the use of the solution as a mouth wash. The physician, however, orally directed the plaintiff to use the solution in her eyes also. The drug company to which the plaintiff took the prescription gave her, not a 1 per cent solution of gentian violet, but a 3 per cent solution, and this, when used as an eyewash, caused the plaintiff to lose her eyesight. She sued the drug company. The trial court sustained the demurrer interposed by the drug company. The plaintiff then appealed to the court of appeals of Georgia, division No 1.

The defendant drug company apparently contended that it was not liable, because the prescription indicated on its face that it was to be used as a mouth wash, that the use of the 3 per cent solution erroneously dispensed would have been safe for that purpose, and that the drug company could not anticipate that the solution would be used as an eye wash also. The company apparently relied on the rule that a person charged with negligence is liable only for those injuries which a prudent man, in the exercise of care, could have reasonably foreseen or expected as the natural and probable consequence of his act. But, said the court, it is not necessary, after negligence has been proved, to prove also that the consequences of that negligence could have been foreseen by the defendant. It is sufficient if the injuries are the natural result of the negligence, such injuries as are likely under ordinary circumstances to ensue from it. A druggist, the court pointed out, impliedly warrants that the article that he sells is the article called for and is liable for injury that results from his giving the purchaser a different article. In the opinion of the court, the proximate and legal cause of the plaintiff's injury, under the allegations of the petition, was a matter for the jury to

determine. The trial court erred in sustaining the defendant's demurrer. The judgment of the trial court was accordingly reversed—*Watkins v Jacobs Pharmacy Co* (Ga), 171 S E 830.

**Accident Insurance Suturing of Wound a Part of Surgical Operation or of Medical Treatment**—The defendant association issued a policy of insurance providing certain benefits if the insured should die from external, violent and accidental means. No benefits were to be paid, however, for any injury caused wholly or in part, directly or indirectly, by surgical operations or medical treatment or for death resulting from any such cause. The insured died from tetanus, following a herniotomy. His widow, the beneficiary under the policy, sued the insurer to recover the benefits named in the policy. The parties to the suit agreed that the insured was subjected to a herniotomy, that the herniotomy was successful and in no way caused or contributed to the death of the insured, which was due to tetanus, and that the operating physician used a kangaroo tendon suture in closing a part of the opening in the patient's abdominal wall, which suture, without the knowledge of the operating physician, contained tetanus germs, which infected the insured and caused his death.

The plaintiff contended that since, according to the agreed facts, the operation for hernia was successful and in no way caused or contributed to the death of the insured, the cause of death was wholly separate and apart from the operation. We think, however, said the Supreme Judicial Court of Massachusetts, Suffolk that "tying up and closing a portion of the opening in the abdominal cavity" was a necessary part of the surgical operation or, if not connected with that operation, was a necessary part of the medical treatment. Recovery of benefits under the policy was therefore denied and judgment entered in favor of the insurer—*Pitman v Commercial Travelers Eastern Acc Assn* (Mass), 188 N E 241.

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

**Menopausal Symptoms Following Hysterectomy**—Tamis determined the ovarian function of eighteen hysterectomized women by means of the extraction from the urine, of estrogenic substance and anterior pituitary-like hormone. The absence of estrogenic substance and the persistent presence of the anterior pituitary-like hormone indicates ovarian failure. The presence of estrogenic substance indicates ovarian follicular activity. The duration of ovarian function did not bear any relation to the amount of gonadal tissue conserved. Ovarian activity persisted longer in the women less than 35 years of age at the time of operation than in the older group. Conservation of the ovaries in the women less than 35 years of age tended to retard the onset of the "flushes" to a greater degree than in the older group. In both groups, when the flushes did occur, they lasted longer than when they appeared in the bilaterally oophorectomized women. Determination of the ovarian function preoperatively in amenorrheic cases in which this activity is questionable may aid the surgeon in deciding beforehand the problem of gonadal conservation in the treatment of fibromyoma of the uterus. No direct relationship could be demonstrated between follicle hormone production

alone and the onset and severity of the vasomotor disturbances of the menopause. Whatever influence the ovary exerts over these symptoms is due to some other mechanism. The author suggests that the gynecologist not only attempt to conserve the ovaries when treating uterine fibroids but also to save as much of the uterine mucosa as may be feasible. It is the latter procedure that is probably of greatest value to the patient in the prevention of the appearance of menopausal symptoms.

**Acute Yellow Atrophy of the Liver in Pregnancy**—Stander and Cadden report a case of acute yellow atrophy, occurring in a woman at term. Initial symptoms of vomiting, dizziness and headache appeared four days before admission to the hospital and seven days before death. A great deal of stress should be laid on such symptoms occurring near term, and if a satisfactory explanation cannot be found the patient should be admitted to a hospital for careful study. When the diagnosis of acute yellow atrophy is made, the therapy of choice is massive doses of dextrose. Should acidosis develop, alkali therapy is indicated. In the authors' case, dextrose therapy was undoubtedly started too late in the course of the disease. The blood and urine chemical observations in this patient were consistent with injury to the liver and similar to those seen in partial removal of the liver in dogs. The pathologic observations showed advanced fatty degeneration throughout the entire lobule. This fatty degenerative change extended from the central vein to the portal spaces.

**Sterilization by Coagulation of the Uterine Cornu**—According to Hyams, sterilization by coagulating the uterine ends of the fallopian tubes is simple and can be carried out in the office. Anesthesia or hospitalization is unnecessary, as the instrument can be introduced with little or no pain or trauma. No after-treatment is needed and the results are effective. The author does not advise sterilization by this procedure during a menstrual period. If the uterine cavity is distorted by submucous fibroids or by the pressure of uterine tumors, the openings of the fallopian tubes cannot be reached. In the presence of an acute or subacute inflammation of the pelvic organs, polyps, hydrosalpinx, hematosalpinx or pyosalpingitis, treatment by this method is contraindicated.

**Life Cycle, Sites of Predilection and Relation of Aschoff Body in Rheumatic Fever**—Gross and Ehrlich base their study of the life cycle of the myocardial Aschoff body on an examination of the clinical records and necropsy material from seventy cases that presented Aschoff bodies in the myocardium. It appears that these specific lesions pass through three stages in development. The earliest phases,

represented by small cell coronal and reticular Aschoff bodies, have been found to occur up to the fourth week after the onset of the illness. The middle phases, represented by large cell coronal, syncytial coronal, mosaic and large irregular cell polarized Aschoff bodies, have been found to occur between the fourth and thirteenth weeks after the onset of the illness. The late phases are represented by polarized Aschoff bodies that occur from the ninth to the sixteenth week after the onset of the illness, and subsequently by fibrillar Aschoff bodies that occur after the thirteenth week of the illness. The earliest type of specific lesions are apparently influenced in their response by the reactivity of the tissue, depending on whether there has or has not been a previous attack of rheumatic fever, and also by the state of the collagen present in the interstices between the myocardial bundles.

**Disappearance of Glomeruli in Chronic Kidney Disease**—Moritz and Hayman show that both in chronic renal disease in man and in experimentally produced glomerular injury in rabbits a large proportion of the glomeruli in a given kidney may disappear, leaving no recognizable trace. In the rabbits, in which the disease was not progressive, there was not even any condensation of the interstitial connective tissue to indicate the loss of parenchyma. In man the chronic progressive nature of the disease made interstitial fibrosis a constant observation, even though the recognizable glomerular scars were not numerous enough to account for more than a fraction of the obliterated glomeruli. The reduction of the number of glomeruli was not paralleled by a corresponding reduction from the expected normal weight of the kidney. If so large a proportion of the glomeruli in chronic renal disease can disappear without trace, the final histologic examination of the kidney may give less information concerning the pathogenesis and severity of the disease than is commonly thought. If a kidney, having originally an expected normal number of about one million glomeruli, can lose as many as three fourths of these without leaving recognizable scars of those lost, it is not fair to assume that the changes affecting the remaining one fourth were necessarily the same as those that occurred in the glomeruli that have disappeared. The final pathologic diagnosis of the kidney is frequently made on a basis of the preponderant change seen. This may involve a weighing of the evidence of arteriolar sclerosis against the evidence of inflammation. If complete glomerular disappearance occurs to the extent indicated in this investigation, the final pathologic picture may throw but little light on the pathogenesis of certain types of chronic renal disease.

**Extragenital Chorionepithelioma in a Man**—Kantrowitz presents a case with necropsy observations in a man, aged 22, having a primary teratoma of the anterior mediastinum containing chorionepitheliomatous elements. The tumor invaded the superior vena cava, studding both lungs with chorionepitheliomatous nodules. Careful gross examination revealed no metastases in the other organs or lymph nodes. The genital tract (testicles, vas deferens, seminal vesicles and prostate) showed no tumor nodules. The testicles were sectioned in 2 mm blocks, and slides were made from each block. Examination revealed no tumor nodules. Microscopic examination of the tumor revealed teratomatous and chorionepitheliomatous elements. Only chorionepithelioma was found in the pulmonary metastases. The testicles showed no neoplastic elements. Marked interstitial cell hyperplasia of the testicles was seen. These observations refute the contention of Prym and Oberndorfer that in man chorionepithelioma always goes together with tumors of the testicles. The Aschheim-Zondek test was positive in both the urine and tumor tissue extracts.

**Primary Carcinoma of Lung, Treated Successfully**—Young treated a case of primary carcinoma of the lung by lobectomy. The patient is fit and well two years after operation. The type of operation followed, namely, trapdoor thoracotomy, proved in every way satisfactory. It gave excellent exposure and the utmost freedom to the operative technic of removal. The individual ligation of entering arteries and returning veins seems, when practicable, to be preferable to mass ligation of the stump as practiced by many operators today. It is questionable whether this procedure of individual ligation need add materially to the duration of the operation. The chief difficulty would seem to be in respect to the effective closure of the bronchus, but this difficulty should be readily enough overcome if a small portion of lung tissue is left, which may be closely sutured over the crushed, ligated and inverted stump of the bronchus.

**Venous Obstruction in Upper Mediastinum**—Pilcher and Overholt found fifty patients in a group of surgical patients harboring lesions in the upper chest and the mediastinum who showed evidence of obstruction of the superior vena cava or innominate veins. Many of these patients complained of symptoms that were attributable to the effects of the disturbed venous circulation. Dilatation of the neck and arm veins was the most common physical sign. In many of these patients, however, dilated veins were not visible and definite symptoms were lacking. In these patients the presence of venous obstruction was discovered entirely by measurement of the venous pressure. It is therefore important in the study of patients with lesions in or near the mediastinum to measure the venous pressure directly in order to determine accurately the status of the upper venous system. In the great majority of the fifty patients it was possible to relieve the obstructive lesion surgically. In a few cases radiation therapy was effective. Venous pressure estimations taken at intervals postoperatively were particularly valuable in determining the degree of relief of the venous obstruction. Relief of symptoms accompanied the restoration of the venous pressure to normal in each case.

**Intestinal Obstruction**—Meyer and Spivack observed that the mortality of surgically treated cases of acute intestinal

obstruction has been reduced but little in the last twenty-five years. In their series of 505 cases it was 48.6 per cent. The high mortality is due to late surgical intervention when the "triad" of symptoms is present. This "triad" appears late, when the patient is practically moribund. Injection of physiologic solution of sodium chloride and dextrose cannot compensate for the damage of delay and does not influence appreciably the degree of mortality. The mortality will be reduced appreciably only by early operation and this will be possible only when early diagnoses are made. An early diagnosis is possible only by taking flat roentgenograms as a routine measure. A "herring-bone" appearance shows the earliest stage of obstruction, a "step-ladder" appearance shows a more developed process and "fluid levels" show the well advanced intestinal obstruction. In every postoperative abdominal case in which intermittent abdominal pain arises it is advisable to take a roentgenogram by a portable apparatus and not to wait until the grave "triad" appears.

**Pemphigus**—Grace confirms Kissmeyer's original observation of a progressive diminution in the number of eosinophil leukocytes with increasing activity of the clinical condition in two cases of pemphigus. Bacterial strains, obtained in one instance sixteen days and in the other thirty-one days before death, were found to be identical with strains obtained from the cardiac blood at necropsy. Absorption of bacteria into the blood stream from the base of a purulent bulla is not an unlikely happening in a debilitated condition such as these patients showed at the time the bulla fluids were examined. It is also known that bacteremia or toxemia resulting from the activity of pyogenic organisms can produce a total and differential white blood picture such as these patients showed and can also be associated with temperature charts similar to those obtained in these cases. Therefore the author is of the opinion that there was a progressive, subacute bacteremia in the two cases beginning at approximately the time of aspiration of the bullae and that this bacteremia was responsible for the change in the leukocyte picture.

**Autolysate Therapy for Verruca Vulgaris**—Cormia prepared a wart autolysate in accordance with the methods suggested by Biberstein and Soule. He treated twelve patients each receiving at least ten injections of autolysate. In only two cases was a cure effected, and here the specific immunologic action was questionable.

**Colloidal Mercury Sulphide in Treatment of Syphilis**—Wakerlin administered a total of approximately 800 intravenous injections of colloidal mercury sulphide to a series of thirty syphilitic patients in various stages of the disease in order to test the antisyphilitic potency of the drug and its suitability for intravenous use. The patients having early syphilis were given an initial course of twenty-four semaweekly injections of 60 mg of the drug followed by alternate courses

of neoarsphenamine, colloidal mercury sulphide and a bismuth compound. The patients presenting more advanced forms of the disease received a course of twenty-four weekly injections of 60 mg of the drug followed by the combination therapy indicated. Colloidal mercury sulphide showed a favorable effect on the lesions and serologic changes of primary and secondary syphilis that was only slightly, if at all inferior to that of the arsphenamines. The patients presenting clinical manifestations of late syphilis also responded favorably to the drug. The serologic response to colloidal mercury sulphide therapy was excellent in early latent syphilis, although the drug was ineffective in reversing the positive Wassermann reactions in long standing latent or congenital syphilis if the patients had previously received approximately four years of more or less regular treatment with standard antisyphilitics. Examinations of the spinal fluid indicated that colloidal mercury sulphide influenced the changes in the spinal fluid neither favorably nor unfavorably. There were no local or systemic reactions by the intravenous administration of the drug. In a definitely therapeutic range of dosage, colloidal mercury sulphide was well tolerated and showed a low incidence of mild mercurialism. A series of twelve or fifteen weekly injections of 60 mg of the drug may be repeated one or more times during therapy. Patients presenting early syphilis who tolerate the arsphenamines poorly may be given an initial course of twenty-four semaweekly injections of 60 mg or twelve weekly injections of 120 mg of colloidal mercury sulphide with the assurance of producing a prompt healing of the lesions and a satisfactory effect on the Wassermann reaction.

**Relationship of Migraine, Epilepsy and Other Neuropsychiatric Disorders**—Paskind compared the prevalence of familial, parental and personal migraine among patients having epilepsy with the incidence among patients presenting no neuropsychiatric disorders and among patients with manic-depressive psychosis, trigeminal neuralgia, psychasthenia, dementia praecox, tic constitutional inferiority and paranoid states. These comparisons indicate that there is no special relationship between migraine and epilepsy and that migraine occurs as evidence of a familial neuropathic trend in the other neurologic conditions studied.

**Primary Ependymitis**—Arnold states that primary ependymitis is a distinct pathologic entity and reports a case of the subacute type. The pathologic changes are characterized by a selective subacute inflammatory process, which involves the entire ventricular system being limited to the ependyma, subependyma and choroid plexus. Should ventricular obstruction not occur in the subacute stage the inflammatory reaction subsides and the condition becomes chronic. The inflammatory process with subependymal glial proliferation tends to occlude the ventricular foramina with the development of obstructive hydrocephalus. The choroid plexus is the most likely portal of entry of the toxins or bacteria. The signs and symptoms are due chiefly to hydrocephalus increased intracranial tension (headache, vomiting, mental changes, papilledema, bradycardia and occasionally convulsions), few, if any localizing signs and

a tendency toward remissions. The disease is simulated by cerebral neoplasm, tuberculous meningitis and syphilitic meningitis.

**Cerebral Complications of Putrid Pleuropulmonary Suppuration**—Cohen reviewed nineteen cases that presented cerebral symptoms complicating pleuropulmonary suppuration, dividing them arbitrarily into three groups: abscess of the brain, aseptic embolus and psychosis. He suggests that a single etiologic factor is present in all groups, namely, an embolus. In the first group the embolus is infected and in the second group aseptic, in the third group it is postulated as a factor in the psychosis.

**Peripheral Arterial Thrombosis**—Mead and Stewart report a case in which a gonorrheal infectious process and the intramuscular injection of milk seem to be etiologic factors in the production of peripheral arterial thrombosis and gangrene in the first three toes of the left foot. The authors failed to find a previous record of the intramuscular injection of milk as a probable etiologic factor in the production of peripheral arterial thrombosis. The reaction of the patient to the injection of foreign protein was in no way unusual, being high temperature, leukocytosis, profuse perspiration, headache, backache, abdominal pain and increased pain in the affected joints. It is not difficult, however, to associate a possible chemical action on the blood with the other etiologic factors in the production of arterial thrombosis. At least the injection of milk was a potential etiologic factor in this case and clinically seemed to exert a potent influence in the production of the thrombotic lesions.

**Influence of Venous Stasis on Heterotopic Formation of Bone**—Roome and McMaster studied the effect of venous

stasis on heterotopic formation of bone induced by transplanting similar portions of mucosa of the urinary bladder into the muscle planes of both hind legs in a series of six dogs. The femoral vein and its tributaries in the upper portion of the thigh were ligated and excised on one side, while the other leg was used as a control. In five cases more bone was formed in the leg with venous ligations than in the control leg, while in one case the amounts were equal, as studied by roentgenograms and by weighing the bone plaques. The bone formed about the transplant increased in density for a period of a few months and then atrophied, although the bone did not entirely disappear from the legs in the one case that was observed for two and a half years. Heterotopic formation of bone is accelerated by venous stasis.

**Pericardiectomy for Advanced Pick's Disease**—Flick and Gibbon performed anterior partial pericardiectomy on a 12 year old boy with advanced Pick's disease. The thickened calcified epicardium was not removed. There was slight temporary improvement after the operation, but death occurred forty-six days later. At necropsy, adhesions were found to have reformed between the heart and the remaining portion of the pericardium. The failure to relieve the patient of his symptoms was attributed to the presence of a thickened epicardium. The author discusses the significance of the low serum proteins found prior to operation.

**Histamine in Treatment of Myositis and Arthritis**—Kling points out that the effect of histamine treatment consisted in a dilatation of the minute vessels and the smaller arterioles and in an increase in the flow of blood and in the permeability of the vessels, which caused a hyperemia and elevation of the cutaneous temperature for a duration of several hours. A definite conclusion as to the value of this method is at present possible only in myositis. Of 376 patients, 343 were cured or improved, recurrences were noted in thirty three patients. Of thirty-two private cases of myositis, twenty four were cured or improved and eight remained unimproved. Immediate relief of pain and tenderness after the first treatment was of favorable prognostic significance. Secondary myalgia due to static unbalance after trauma and strain was benefited in a moderate number of the cases reported. Five patients with subacromial bursitis and two with tenosynovitis were treated successfully. In 151 cases of arthritis reported in the literature improvement occurred in 124, in twenty two cases the arthritis recurred. In twenty-four personal cases of arthritis, fourteen were improved and ten unimproved.

**Study of Pneumococcus Carriers**—In an effort to determine whether the constant carrying of pneumococci in the throat was associated with frequent infections of the upper respiratory tract, Bliss and her associates obtained throat cultures from a group of twenty young adults approximately once a week over a period of two academic years. Of the 1,016 throat cultures that were obtained, 34.5 per cent were positive for pneumococci. After the first year it seemed that indi-

viduals could be divided into three groups with respect to the carrying of pneumococci: chronic carriers, intermittent carriers and noncarriers. However, at the end of the second year it became apparent that those individuals who had been classed as intermittent carriers were, in reality, chronic carriers, for, although few positive cultures were obtained from them and those irregularly, the same type of pneumococcus recurred in their cultures. It was found that there was little difference in the frequency and duration of infections of the upper respiratory tract between the chronic carriers and the noncarriers. While the same type of pneumococcus tends to recur in the throat cultures from a chronic carrier, it is frequently possible to demonstrate the simultaneous carrying of two or three types of pneumococci in these persons if the proper procedures are used. The authors believe that their study adds evidence in favor of the theory of the stability of pneumococcus types in the human being.

- Compensation Aspect of Occupational Dermatitis W J O'Donovan London England—p 223
- Health Hazards in the Foundry Industry W J McConnell and J W Fehnel New York—p 227

**Cause of Bakers' Eczema**—Zitzke, in examining 149 bakers suffering from eczema, found that 41.8 per cent reacted positively to flours not treated with chemicals, but 67.2 per cent showed a positive reaction to flour to which chemicals (ammonium persulphate, acid calcium phosphate and potassium bromate) had been added. Eighty-six of the 149 bakers, or 58 per cent reacted positively to the treated flour, whether the test was a subcutaneous one made with flour containing ammonium persulphate or a patch test with ammonium persulphate. Eight bakers alone reacted positively to ammonium persulphate patch tests, while the subcutaneous method of testing with treated flours gave negative results. The results indicate that the primary injurious substance in the treatment of flour is ammonium persulphate. This leads in most cases to a hypersensitivity of the organism, which occurs only rarely in exposure to pure flour albumin. Whether it is the chemicals alone that produce the hypersensitivity or whether under the influence of these chemicals a molecular change takes place in the albumin which raises its allergic quality cannot be proved by means of examination but can only remain in the sphere of probability.

**Comparative Study of Hearing Tests**—In performing Becker's hearing test, the examiner faces the patient and presses his own auricle against that of the latter, thereby converting his own auditory meatus and that of the patient into closed cavities. If the patient's right ear is to be tested, the examiner places his own right ear against that of the former. A strongly vibrating fork is set on the patient's mastoid opposite the obstructed ear and he is instructed to concentrate on the sound and to inform the examiner of the exact moment when he ceases to hear it. When the patient no longer hears the sound the examiner notes in terms of seconds, the difference between

his own hearing time and that of the patient. In all conditions save that of perceptive deafness in the patient, the examiner and the examined will hear the sound for the same length of time. Therefore it follows that if the examiner hears the sound longer than the patient (making allowance of between three to five seconds for normal variations in the hearing time of the two), the latter suffers from a perceptive lesion. The degree of involvement can be judged by the number of seconds the examiner hears the sound longer than the patient. The conditions under which the two hear the sound of the fork are so similar that the test can be reversed, that is, the examiner can place the fork on his own mastoid with the patient listening to the sound through the former's skull without in the least altering the results.

**Opticofacial Winking Reflex**—In eliciting the opticofacial reflex (closure of the lids when an object is brought suddenly into the field of vision) for testing unilateral or bilateral marked visual impairment or destruction, Weingrow places his hand above, to the side or below the eyes of the subject and out of his field of vision, then he moves it suddenly across the eyes, thus causing a sudden closure of both lids. If one eye is shielded by a cardboard and the other eye stimulated, there results a bilateral closure of the lids. The afferent path of this reflex is the same as that of the emergency light reflex, but the efferent path seems to be confined to the facial nerve. The author reports cases presenting such impairment with the consequent involvement of the opticofacial reflex and gives reference to cases in which the efferent part of the opticofacial reflex arc is involved.

**Gonococcus Complement Fixation Test in Arthritis**—Myers and Keefer observed the results of the gonococcus complement fixation reaction of the blood serums and synovial fluids of forty-three patients having proved gonococcal arthritis and of sixty-six patients having rheumatic fever, rheumatoid arthritis or some other type of arthritis. A positive reaction was encountered in 86 per cent of the cases of gonococcal arthritis. The blood serums of only two of the seventy-one

patients who had joint disease not due to gonococcal infection gave isolated positive reactions. The reaction was doubtful in one patient with rheumatic fever who had a gonococcal prostatitis. The reaction of the blood serum and that of the synovial fluid, simultaneously collected, were with few exceptions identical. The examination of the synovial fluid offered little advantage over that of the blood serum. A positive Wassermann reaction did not influence complement fixation to the gonococcal antigen. The routine employment of this test in the study of patients with arthritis was valuable. In the authors' experience the employment of this test has proved to be of great value in the etiologic diagnosis of chronic arthritis.

 Ectopic Paroxysmal Tachycardia J Wyckoff New York—p 349

**Sweat an Etiologic Factor in Vitiligo**—Roop believes that sweat may be a possible causative factor of vitiligo. His theory is that vitiligo is the result of absorption by the skin of certain decomposition products of sweat which have remained and undergone a chemical change on the skin. This chemical, as yet undetermined, may be ammonia or ammonia carbonate and carbamate and, when so absorbed, depigments the skin by acting as a bleaching agent on the melanin of the pigment cells. The absorptive power of the skin is so definitely acknowledged and readily proved that it is unnecessary to elaborate on this point and it is this function of the skin which contributes to the possibility and plausibility of his theory. During the past summer three women patients consulted the author for treatment of beginning vitiligo, also one middle-aged man with vitiligo of a duration of three years, limited to the scrotum. In this group of cases marked sweating was evident in each case, and the more the author contemplated and checked these cases with vitiligo in general, the more he was convinced that they offered an important clue to the etiology of vitiligo.

 Apparatus for the Measurement of Respiratory Rate R H Landon and W G Brierley—p 75  
 Modification of the Mudd Electro-Ensmosis Apparatus H Klein—p 76

**Use of Absorbent Pulpit in Cultivation of Aerobic Organisms**—Williams describes a method that he has applied especially to fungi to study their aerobic tendencies. The fungi chosen were members of a group that had proved pathogenic to man. An absorbent possessing neither nutritive, antiseptic, chemically nor physically reactive properties is suitable. Blotting paper was chosen. A fast color is desirable, the most suitable color being dependent on the color of the organismal growth to be studied. For adaptation to test tubes, a two-legged pulpit of blotting paper with the horizontal portion above the fluid mediums proved satisfactory. The organism was planted on this portion and its growth observed. Some organisms grew on this portion alone some on it and in the

mediums and some in the mediums alone. When growth occurred in both situations, it often varied in marked degree both in character and in extent. The bacteria tried (*Bacillus subtilis*, *Staphylococcus aureus*, *Bacillus coli*) showed scanty growth on the pulpit and prolific growth in the mediums, while fungi (*Trichophyton interdigitale*, *Epidermophyton inguinale*) grew well on the seat. Growths which, because of their aerobic tendencies, would be inhibited or destroyed by sinking in liquid mediums can be prevented from doing so. The type of growth on the pulpit, on its legs and in the mediums can be observed. The site of growth can be observed. Growths have been carried on the pulpits for over two months and have shown no tendency to dry out. In a control on Sabouraud's proof medium there has been drying. It is necessary to test the absorbent used and assure oneself that it is innocuous.

**Modified Coutard Technic in Roentgen Therapy**—In order to make the Coutard method workable, Martin developed a technic using 200 kilovolts, 0.75 mm of copper and 1 mm of aluminum filter, a target skin distance of 50 cm, and a current of 6 milliamperes. With these settings 300 roentgens can be given in twenty-five minutes with an intensity of 12 roentgens per minute. The author administered fourteen such doses (4,200 roentgens) to a single skin area in sixteen days. A denudation of the skin appeared in three weeks followed by rapid healing and no sequelae during a period of observation of eight months. When this therapy was administered to the side of the neck, the mucous membrane of the throat was denuded after about two weeks and the patient found swallowing difficult for a period of about ten days. However, healing was prompt.

**Desensitization of Nasal Mucous Membranes in Hay Fever and Asthma**—Warwick has employed nasal ionization for the last seven years and he believes that intranasal ionization is the most satisfactory method of desensitizing the individual to pollens and foods, using an alloy of zinc, tin and cadmium as an electrode and the salts of these metals as the electrolyte. A safe, suitable direct current, which has been filtered previously, is best furnished by a special motor generator. Unless the patient is unusually hypersensitive, one treatment is sufficient, and some patients have remained immune for as long as seven years. No damage is done to the nasal membranes by the ionization treatment, as evidenced by laboratory examinations of specimens of tissues from three different cases. The reactions are not only local but systemic. Patients who have had the ionization treatment report that they are less susceptible to colds afterward.

**Subacute Spinocerebellar Degeneration in Elderly Patients**—Greenfield presents two cases of spinocerebellar degeneration. The disease came on in patients aged 66 and 57 years and ran a rapid course, with a fatal termination in three and seven months respectively from the onset of the first symptoms. In both patients, pains in the limbs were a prominent early symptom, this was succeeded by weakness and ataxia of the legs and arms, dysarthria and mental enfeeblement. Nystagmus was indefinite or quite absent, and no loss of skin sensibility was found. There was considerable pleocytosis and excess of protein in the cerebrospinal fluid in both cases. Pathologically, the condition was characterized by degeneration of the long tracts of the cord, especially the dorsal columns and cerebellar tracts, with earlier degeneration of the pyramidal tracts. There was gross loss of Purkinje cells in the cerebellar cortex, the granule cells being relatively spared. The superior cerebellar peduncles and the longer tracts in the tegmentum of the brain stem were involved in the second case. The nucleus of Luys and the strio-Luysian fibers were degenerated in both cases. The substantia nigra, nucleus ruber, nuclei pontis and olivary nuclei were unaffected and the cerebral cortex was intact. In both cases there was fairly intense perivascular infiltration in the neighborhood of degenerated tracts.

**Acquired Myotonia and Postneuritic Muscular Hypertrophies**—Krabbe summarizes the twenty cases of true muscular hypertrophy described in the literature. In six of these cases the muscular hypertrophy developed after typhoid, one developed after a lead polyneuritis, one after sciatica, one after a traumatic lesion of the sciatic nerve and one patient had suffered from pleurisy or pneumonia before developing the muscular hypertrophy. Further, some cases are described in which such polyneuritic symptoms as paresthesia, pain and weakness of the muscles preceded the muscular hypertrophy. In only two cases did hypertrophy seem to have been connected with a cerebral lesion. The relatively numerous cases developing after typhoid have been considered by the authors due to a phlebitis. If the history of the disease is analyzed it seems more probable that the preceding illness had been a neuritis caused by typhoid. On considering these cases as a whole the author observes that true muscular hypertrophy generally develops after a polyneuritic syndrome or after a disease often associated with polyneuritis, and he draws the following conclusions: 1 In the majority of cases a polyneuritis is recovered from completely or it leaves a more or less marked atrophy of the affected muscles. 2 In some cases the recovery is excessive and the muscles hypertrophy. Sometimes a muscle hypertrophies as a whole, presenting normal power or a slight weakness. In other cases the sarcoplasm especially hypertrophies, and in these a myotonic condition will be the consequence of the hypertrophy. 3 If this hypothesis is valid acquired myotonia and true muscular hypertrophy may be considered as two variations of the same abnormality—an abnormal regeneration after neuritic processes.

\*Cineradiography R J Reynolds—p 415

**Cineradiography**—Reynolds believes that cinematography enables one to obtain a rapid, inexpensive and permanent record of the function of active organs. The continuous "band" enables one to study movement for an indefinite period, whereas an ordinary screen examination can be carried out only for a short period. These advantages are especially obvious in organs, such as the heart, of which one is desirous to examine several different parts in a state of movement at the same time. The permanent records of movements may be used for purely diagnostic purposes, comparison with former records, to watch the effects of treatment or the progress of a pathologic condition, teaching purposes and transmission abroad or elsewhere, either for the purpose of obtaining the opinions of specialists as to the nature of the case or for information purposes as to the condition of the patient in the past. The author stresses the fact that the cinematographic method of investigation will add greatly to the knowledge of the functioning of the heart, especially in the various irregularities arising in the cardiac lesion, for instance in a sino-auricular block. Apart from the clinical uses there are other fields of usefulness: the investigation of physiologic problems when opaque mediums may be injected into the circulatory system in animals.

**Perineo-Abdominal Excision of Rectum.**—Gabriel discusses the merits of perineal excision of the rectum compared with abdominoperineal excision. There is a field of usefulness for each operation, provided it is recognized that usually a combined abdominoperineal or a perineo-abdominal excision (the latter of which is the better method) is definitely more radical than a perineal excision. There are two possible exceptions to this rule. 1 Recent cases in which there is a single small mobile carcinoma in the middle or lower third of the rectum without glandular metastasis or evidence of related adenomas above the growth. In such cases a perineal excision is as radical and as effective in curing the patient as an abdominoperineal excision. 2 Advanced cases in which pre-operatively it is possible to demonstrate digitally extrarectal spread in the form of nodules or indurated lymph nodes outside the rectal wall. These are advanced cases with marked lymphatic spread and if considered "operable" are certainly inoperable by the perineal route and probably are equally inoperable by a combined excision. The author has performed the perineo-abdominal operation in one stage in twenty-five cases of cancer of the rectum. There have been five operative deaths: two deaths occurred on the operating table, one occurred on the fourth day and was clearly due to cardiac failure with auricular fibrillation, and two occurred on the seventh day from a combination of small intestinal ileus and bronchitis, this happened before the author had begun the prophylactic injections of ampoules of pitressin. He believes that the justification for the operation in these cases is that microscopic proof of metastases in the glands along the line of upward lymphatic spread has been obtained in fourteen of the twenty-five cases. He is now restricting perineal excision to cases of carcinoma of the anal canal or lower third of the rectum in which the tumors are either very recent or so advanced that, by reason of involvement of the vagina, prostate or ischio-rectal fossa, the extra risks of a combined excision do not appear to be justified.

**Displacement of Internal Epicondyle into Elbow Joint.**—Roberts reports four cases in which displacement of the internal epicondyle into the joint has been reduced by manipulative measures alone. He states that there is no reason to suppose that recovery of the ulnar nerve lesion or the ultimate function of the elbow will be prejudiced by this line of treatment. Stress is laid on the importance during manipulation of opening the inner side of the joint so as to allow the internal epicondyle to retrace its original displacement. In the absence of operative treatment there is the possibility of fibrous union of the epicondyle occurring, but this is of no importance, as fibrous union of the epicondyle occurred in two cases which had been submitted to open operation and in which the epicondyle had been sutured in its correct position. It appears likely that attempted manipulative reduction will be successful in a high proportion of cases seen within the first few days and that the necessity for open operation will be avoided, with consequent shortening of convalescence and prevention of any possible complications.

**Scope of Thoracic Surgery.**—Adeney points out that it is by the understanding of one another's problems that the physician, the surgeon, the radiologist and the pathologist together have contributed to the enlargement of the scope of thoracic surgery. The main complaints for which relief is provided are hemoptysis, chronic cough, dyspnea and general toxemia. Of these, perhaps the chief pitfall that the profession is now only too slowly learning to avoid is that of attaching unjustifiably to the patient with hemoptysis or chronic cough the label of tuberculosis or chronic bronchitis, and then in the former case relegating him forthwith to the limbo of a sanatorium, or in the latter regarding him as hopeless save as a receptacle for the multitudinous inventions of the ingenuity of the manufacturing chemist. It may be that in hemoptysis it is wise to diagnose phthisis until it is disproved with the aid of negative roentgen and repeated sputum examinations. In the case of hemoptysis the wise clinician will consider the possibility of dry or hemorrhagic bronchiectasis and of neoplasm, either of which may yield to surgery. As with hemoptysis, so with chronic cough, which used to be labeled so readily chronic bronchitis or tubercle. Even now the real cause is overlooked, such as chronic empyema, lung abscess or bronchiectasis. Thoracic surgery, of all the fields of the surgeon's enterprise, is the one field of surgery prolific with perhaps the brightest prospects of future achievement, but withal one in which the wise man will learn by constant practical experience of its problems to temper his enthusiasm with a fair assessment as well of the dangers as of the benefits of his intervention.

**Investigation of Ferments in Uterine Cancer.**—Nakahori measured the quantity of amylase in the carcinoma tissue, lymph nodes, mucosa and muscular layer of the uterus by the twenty-four hour method of Wohlgemuth. He found that the optimum of amylase in these tissues lies between 68 and 74. The quantity of amylase varies greatly in each carcinoma tissue. In the carcinoma of immature type there is a greater quantity of amylase than in the mature type. The amount of amylase in some cauliflower-shaped carcinomas is very high. The amount of amylase in a lymph node is almost constant, no matter whether it is infiltrated by carcinoma or not. The amylolytic power of the endometrium of a cancerous uterus is almost the same as that of a noncancerous uterus. The quantity of amylase in the muscular layer of a cancerous uterus shows no specific change.

\*Gonorrheal Serum Reaction in Cerebrospinal Fluid J Gadrat —p 576

**Gonorrheal Complement Fixation in Cerebrospinal Fluid**—As antigen in the gonorrheal serum reaction of the spinal fluid, Gadrat used the antigonococcus vaccine of the Pasteur Institute and as complement, fresh guinea-pig serum. He used a mixture of equal parts of 1:5 suspension of sheep blood cells and hemolytic serum in a dilution fixed by its dosage. The reaction is made with six tubes, three of them being controls. Five-tenths cubic centimeter of cerebrospinal fluid is added to each. Two tenths cubic centimeter of antigen is added to each, except for the three controls, to which an equal portion of physiologic solution of sodium chloride is added. To the three test tubes 0.1, 0.15 and 0.2 cc. of complement is added. The tubes are incubated for three quarters of an hour. Then 0.2 cc. of the hemolytic mixture is added throughout, and the tubes are incubated for three quarters of an hour and read. A weakly positive reaction is accepted when there is no hemolysis in tube 1, i. e., with 0.1 cc. of complement, a positive reaction when there is an absence of hemolysis in tubes 1 and 2, and a strongly positive reaction when there is no hemolysis in any of the three tubes. These tests were made on 115 patients. It was found that the reaction was positive in the cerebrospinal fluid in about 66 per cent of blenorrhagias, usually complicated. In some cases it remains positive longer than in the blood and survives both clinical and bacteriologic cure. This serologic characteristic exists without other cytologic or chemical alteration of the spinal fluid. It is independent of the Wassermann reaction. It allows the tracing of a certain number of latent gonorrheal infections.

**Lesions of Acute Barbiturate Poisoning**—Carriere and his co-workers carried out experimental studies on the lesions in rabbits resulting from the oral ingestion of fatal doses of a barbiturate preparation. Different organs and systems were examined and are described in detail. The changes, which affected all the organs, were hyperemia with capillary and venous congestion, fatty degeneration and terminal infection except at the level of the lung, where a pneumonic process is often early. These are the three general characteristics of acute barbiturate poisoning. One can thus say that the barbiturates are fatal by initiating a degeneration of the entire protoplasm.

Comparative Study of Treatment of Frambesia by Different Arsenicals and by Potassium Iodide. S Golovine —p 959

**Action of Splenic Extracts on Diabetic Patients**—Because of the experiments with splenic extract on normal and diabetic dogs showing its influence on glycemia, Rathery and his co-workers studied the action of the extract in human diabetic subjects. This study was divided into three parts: the action of the splenic extract on free and combined blood sugar, the action on the glycemic variations following the ingestion of dextrose, and the action on the variations in glycemia resulting from the injection of insulin combined with the ingestion of dextrose. The preparation employed was an extract of defatted and deproteinized spleen. In general (eight out of ten cases) the intravenous injection of this preparation in diabetic patients produced a fall in the free sugar the

maximum being attained at the end of an hour and a half. The percentage fall varied from 5.1 to 31. The phenomenon begins to decline at the end of about three hours but exceptionally may persist. The combined sugar usually falls, the maximum being attained often during the first half hour. The association of intravenous splenic extract injection with the test of hyperglycemia produced in diabetic patients by the injection of dextrose retards the appearance of free sugar hyperglycemia but seems to increase the intensity and duration. The association of intravenous injection increases, sometimes remarkably, the effect of insulin on the free sugar during the test of provoked hyperglycemia. It would perhaps be advantageous in some cases of diabetes to use the favorable action which the extract exercises on insulin.

**Medical Treatment of Chronic Cholecystitis**—Chiray and his collaborators found by accident the sedative effects exercised by certain calcium salts injected intravenously and parathyroid extract intramuscularly on painful cholecystitis. Patients with chronic cholecystitis obtained an improvement in general condition by calcium intravenously, a spontaneous decrease in pain (often even disappearance of pain on palpation) and a modification of painful attacks which became less frequent and less severe. The method that they used was the daily, or alternate daily, injections of 5 cc. of a 10 per cent solution, each treatment comprising from ten to fifteen injections. The parathyroid extract was administered subcutaneously in daily doses of 1 cc., each series consisting similarly of from ten to fifteen injections. Sometimes these substances were alternated in the same patient, and sometimes only one was used. Nine cases are reported in which this method caused important improvement in almost all. It is probable, they believe, that the sedative action on the biliary passages is due to increase in the biliary calcium. This method may be used either as a preliminary to surgical intervention, with the advantage of increasing the blood coagulability and improving the general state, or as basal medical treatment in the course of various painful conditions of the gallbladder.

**The Chlorides in Meningitis**—If there is a possibility of using the quantity of chlorides in the cerebrospinal fluid in meningitis as a prognostic sign, Finkelstein and Merson recognize the necessity of observing the oscillations of the chlorides in the course of meningitic processes of different types. The material for their studies comprised twenty-three cases of epidemic meningitis, nine of tuberculous meningitis, one of purulent meningitis, four of aseptic serous meningitis, one of syphilitic meningitis and the remaining without alteration of the meninges, a total of forty-one cases. The procedure was as follows. The urine was collected for twenty-four hours the same day the gastric secretion was examined after a test breakfast. After this, blood was drawn for chloride determinations, and finally lumbar puncture was performed. The quantity of chlorides found in the spinal fluid normally varied from 720 to 740 mg per hundred cubic centimeters. They concluded that the quantity of chlorides of the spinal fluid in serous meningitis did not deviate from normal. In mild cases of epidemic meningitis the chlorides were only slightly lowered.

The decrease in chlorides progresses with the severity and duration of the process. In dangerous cases, values even lower than that of the blood are obtained. In tuberculous meningitis the diminution of chlorides is more accentuated than in epidemic meningitis. The quantity of cerebrospinal fluid chlorides may often serve as a good differential sign between meningismus and serous meningitis on the one hand and tuberculous meningitis on the other. Increase in the chlorides of the spinal fluid is a favorable prognostic sign, decrease is unfavorable. Diminution of cerebrospinal chlorides in meningitis depends not only on demineralization of the blood plasma but on the general demineralization of the entire organism. To hinder the demineralization of the organism with meningitis, it is important to look after the food and reinforce it as much as possible with mineral constituents.

**Abdominal Pains in Childhood**—Guerstein and Reydermann believe that careful history taking and abdominal palpation of children with abdominal pains will often permit the diagnosis of angiocholecystitis. The best confirmation is given by the method of duodenal sounding with evacuation of the gallbladder with the help of concentrated solutions of magnesium sulphate described by Lyon. Most of the patients examined had an angiocholecystitis without calculus. The authors feel that in an important group of children with abdominal pain, especially in the region of the umbilicus or higher, a simple angiocholecystitis is the explanation and that the duodenal sound method is a valuable accessory diagnostic aid.

Discussion of the Cancer Problem and the Public A Soland —p 698

**Involvement of Hip Joints in Polyarthritides**—Kienbock calls attention to the fact that occasionally the hip joints become involved in infectious polyarthritides and that it may happen that the floor of the acetabulum is forced toward the pelvis, so that a pelvic protrusion of the acetabulum results. The arthritis may be of various types: it may be a nonspecific infectious arthritis, which is generally acute but may also be chronic, it may be the acute, chronic arthritis of gonorrhea, or it may be an articular tuberculosis, in which there are recurrent inflammatory attacks. Roentgenologic and anatomic observations have revealed that in the course of an inflammation of the articular capsule and of the destruction of the cartilaginous coverings by the formation of granulation tissues and pannus the osseous acetabular floor becomes decalcified, softened and occasionally partly destroyed. The pressure from the head of the femur deepens the acetabular floor and forces it toward the center and slightly upward. Following cessation of the inflammation, the acetabular floor hardens again and the roentgenogram reveals a pelvic protrusion. The author points out that Breus in 1913 differentiated three stages in the development of this disorder, and he shows that the process is a sort of wandering of the acetabular floor, which may progress gradually. The joint either becomes fixed in contracture and ankylosis, or its motility may be reestablished; the latter is possible only in rather mild cases, and later there often appear progressive changes of the bones, which are noticed in primary deforming arthrosis. The author reports the histories of two patients. In both cases there existed a bilateral, infectious inflammation of the hip joint with partly slight and partly severe protrusion of the acetabular floor. The first patient was a woman, aged 54, and the second a boy, in whom the pain of the hip joint set in at the age of 13. This second case is especially worthy of note because the disorder is comparatively rare in children and young persons. The author calls attention to similar changes in the hip joint, which develop in other diseases, such as tabetic arthropathy, Paget's disease, osteomalacia and osteolytic cancer metastases. However, these rather extensive skeletal changes should be differentiated from the described local changes caused by articular disease.

\*Oleoathorax in Treatment of Pleuropulmonary Diseases L Capani —p 9

Catarrhal Icterus in Pulmonary Tuberculosis P Marin and O Del Piero —p 16

**Oleoathorax in Treatment of Pleuropulmonary Diseases**—Capani found that in antiseptic oleoathorax the late results have always been satisfactory in cases treated for tuberculous empyema. Two cases of septic empyema with pleuropulmonary fistula treated with oleoathorax afforded excellent results. In adhesive oleoathorax, late observations also confirmed the immediate success of the treatment. The author was constantly successful in keeping the pleural cavity and the collapse effective with the subsequent hypertensive pneumothorax. He attributes little importance to the collapsing action of the oleoathorax in lesions opposing pneumothoracic collapse. In one case of pleuropulmonary fistula complicated with valve and empyema in full oleoathoracic treatment the oleoathorax was repeated after emptying, and closure of the fistula and sterilization of the pleural cavity were obtained. On lesser indications of the oleoathorax, such as flexible mediastinum and insatiable pneumothorax, the method seems to be responsive if applied prudently and only in cases of extreme necessity. In all cases the observations after a lapse of some years from the suspension of the oleoathorax revealed a constant and strong secondary sclerosis of pleuritic origin, which has always been increasing. Since this phenomenon is so constant, the author maintains that the cause of it may be found in the action of the aromatized oil that is used in the oleoathorax. It cannot be determined how much of this action may be attributed to the aromatized oil and how much to the simple mechanical action of the liquid, which seems to have great importance. Pleuroscopic observations after the suspension of the oleoathorax revealed considerable pleural reaction, which rendered the serosa completely opaque; the pleural surfaces seemed to be covered with layers of fibrin. The aspect of the pleura must be interpreted as a reaction that has its beginning in the process of pleuritic fibrosis observed long after the suspension of the oleoathorax.

Significance of Experimental Research on Syphilis for Human Syphilology R Brandt —p 193

\*Occurrence of Invisible Form of Causal Agent of Syphilis J Van Haelst —p 212

Ulcers of Vulva Following Tonsillectomy in Child K Steiner —p 220

Leukoderma Following Relapsing Herpes Simplex F Kalz —p 226

**Invisible Form of Causal Agent of Syphilis**—Van Haelst states that there is a granular, ultraviolet-visible form of the causal agent of syphilis. From the fact that spirochetes are rarely demonstrable in the lymph nodes of rabbits and that in spite of this these organs are highly infectious, it has been assumed that the spirochete represents only one phase of the developmental cycle of the causal micro-organism of syphilis. The discussions on the invisible form of the organism induced the author to investigate whether there is a difference in the manifestation developing after the inoculation of organs containing large numbers of spirochetes and of those that are free from spirochetes. He found that the incubation period is the longer as the quantity of the infectious inoculation material is smaller. Studies on the threshold of infection revealed that in rabbits the threshold is higher in the syphiloma than in the lymph nodes, however, the difference in the two thresholds does not correspond to the number of spirochetes contained in the two structures. The infectiousness of the lymph nodes of the knee is generally from ten to fifteen times less than that of the syphiloma, in spite of the fact that the ratio between their content in spirochetes is still smaller (1:200). The infectiousness of the inguinal lymph nodes that have been removed during the stage of the florid chancre approaches that of the syphiloma, in spite of the great difference in the number of spirochetes contained in the two. To determine whether these differences justify the assumption of the existence of an ultraviolet-visible form of the pathogenic agent of syphilis, the author

subjected the emulsions from the fresh organs to careful studies and succeeded in demonstrating the presence of spirochetes in nearly all the infectious organs, although the tissues were apparently free from spirochetes. The author reaches the conclusion that the syphilis infection is always due to infection with *Spirochaeta pallida*. For the apparent contradiction between the nearness of the thresholds of infection of syphilomas and lymph nodes and the great difference in the number of spirochetes that are present in the two structures, the author assumes that the few organisms that are present in the lymph nodes have acquired a high resistance by being exposed to the influence of antibodies. However, the majority of the organisms present in the syphiloma have been influenced only by the locally formed antibodies and their resistance has decreased, so that their infectiousness has been partly lost.

**Pathogenesis and Therapy of Psoriasis**—Grutz recapitulates his studies on psoriasis (*Klin Wchenschr* 12 373 [March 11] 1933, abstr *THE JOURNAL*, May 27, 1933, p 1729), in which he proved that psoriasis is caused by a disturbance in the fat metabolism and that it can be counteracted by a diet deficient in fat. He gives instructions about the foods that should be avoided. He stresses particularly all types of fats (bacon, lard, butter, cream, oil and so on), meats with a high fat content (pork, mutton, goose, duck and so on), certain fish (eel, herring, salmon, carp and all fish roe) and egg yolks, the latter on account of their cholesterol content. Cakes and other baked foods containing fats must likewise be avoided. Permitted are lean meats, fish with a low fat content, soups and vegetables, provided they have been prepared without fat, fruits and berries, preserves and fruit juices and various breads that have been prepared without fat. On such a diet, obese patients with psoriasis frequently lose weight, while patients of normal weight do not, provided their calory requirements are adequately supplied in the form of carbohydrates and proteins. Emaciated persons with psoriasis have even been known to gain in weight under the influence of the fat deficient diet. The author discusses the possibility that just as the carbohydrate tolerance differs in diabetic patients there may be a difference in the fat tolerance of psoriatic patients. On the basis of clinical manifestations this seems probable, for in some patients a slight reduction in the fat intake is effective, while in others a more strict regimen is necessary. Moreover, it is advisable to investigate whether the fat synthesis is disturbed in psoriatic patients. The author reports that in some patients the results of the fat deficient diet are already noticeable after two or three weeks, while in others six weeks or even several months are necessary to reveal the effects. In some patients the psoriatic lesions spread in area but decrease in depth shortly after the onset of the treatment, and there may also be a temporary increase in scaling but this should not tempt the physician to interrupt the treatment, for this "becoming acute" is only temporary and the continuation of the diet will finally effect the complete disappearance of the lesions.

**Diabetes Insipidus and Interbrain**—Gaupp reports the case of a man, aged 35, who, after an automobile accident that resulted in a concussion of the brain, loss of consciousness and vomiting, developed a severe diabetes insipidus and a mild hemiplegia of the left side. Substitutional hormone therapy was effective in the beginning, but after several months it failed completely. In addition to slight psychic disturbances (alteration of hypothymic and hyperthymic phases) and insomnia, the patient had attacks of headaches, perspiration, increase in temperature, vomiting, anesthesia of the paralyzed side, anginous cardiac disorders, mild ileus and, in the beginning under the influence of medication with the hypophyseal preparation, also an inhibition of the diuresis, apparently of spastic origin. During and after these attacks, a state of excitation became manifest with a tendency to destruction, aggressiveness and irresponsible running away. During one attack the patient attempted suicide. The author points out that many aspects of this psychoneurologic syndrome resemble those of acute epidemic encephalitis, in which the inflammatory changes are limited to the interbrain and midbrain. The author points out that in epidemic encephalitis the water and sodium chloride metabolisms are likewise occasionally involved. The psychic changes are known as symptoms of the interbrain. The insomnia, the temporary increases in temperature and the symptoms indicating changes in the autonomic nervous system (spastic contractions of the smooth muscles) can be traced to an involvement of the third ventricle. The clinical symptoms alone do not permit definite conclusions about the type and extent of the traumatic injury of the brain, but it is probable that considerable impairments in the region of the interbrain must have resulted from the trauma. It is likely that the pathologic process extends into the right peduncle, but whether beyond that the tuber cinereum or even the hypophysis is involved is unknown. He reviews the experimental results and the pathologic changes in diabetes mellitus reported by Staemmler. He reports his own observations based on the studies of Scharrer, who first called attention to the fact that in fishes reptiles and amphibians the interbrain contains ganglion cells that have a secretory activity. Similar observations were made in mammals, and in collaboration with Scharrer the author has made studies on a human subject. He concludes that the hesitation to speak of a hormone formation in the brain has been overcome.

**Treatment of Meningitis with Roentgen Rays**—A review of the literature convinced Hippe and Lickint that roentgen rays have produced favorable effects in some cases of serous meningitis. Opinions still differ regarding the efficacy of roentgen rays in tuberculous meningitis, but most of those who have tried it report unsatisfactory results. Epidemic meningitis, particularly the subchronic and chronic form, has been known to be influenced favorably by roentgen treatment. The authors relate the history of a man, aged 24, in whom the meningitis involved more and more the spinal portion, so that extreme pain was felt along the entire spinal column. In spite of repeated lumbar and cistern punctures and of continued medication with methenamine, the symptoms became more severe. Gradually, in the course of several months, the aspects of chronic spinal meningitis developed. Since all other measures proved ineffective, it was decided to resort to roentgen treatment. The entire spinal column and the occiput were divided into seven fields measuring 10 12 cm, and 20 per cent of the unit skin dose was applied to each field. The tension was 160 kilovolts, the current strength 6 milliamperes, the filter 0.5 mm of copper and 1 mm of aluminum, and the distance 30 cm. The irradiations were given at intervals of from two to four days. Four series of seven sessions each were given in the course of three months. Thus each field received 80 per cent of the unit skin dose. The result of this treatment was that quite early in the treatment the pain in the spinal cord was considerably reduced. After approximately one half of the treatments had been given, the fever decreased and the appetite increased. The patient gained in weight and the sedimentation speed (Westergren) fell from 48 to 16 mm. After sixteen months the patient was discharged from the hospital and was able to work. During a period of two years he has been free from relapse. The authors recommend roentgen therapy for similar cases of chronic meningitis.

**Indications for Nonspecific Therapy of Neurosyphilis**

Kral says that the best protection against a late involvement of the central nervous system is thorough treatment of the syphilitic patient during the early stage of the disease. His neurologic clinic stresses the necessity of subjecting the syphilitic patient to spinal puncture five years after the infection. Patients who then have a positive reaction in the cerebrospinal fluid should be subjected to an effective prophylactic treatment. The specific therapy is not sufficient, and the author thinks that in these latent cases, with a positive reaction in the cerebrospinal fluid, fever therapy with subsequent antisyphilitic treatment gives the best results. Malaria therapy with arsphenamine and bismuth compounds subsequently is the method of choice for these patients. The author considers malaria therapy advisable in all cases of late latency in which no special contraindications exist, such as decompensated cardiac defects, active tuberculosis, renal diseases, great obesity or severe cachexia. He suggests that in the latter cases the malaria therapy be replaced by treatment with bacterial proteins.

**Liver Preparations in Treatment of Bullous Oral Exanthems**—Sebba points out that the bullous, pemphigus-like processes of the oral mucous membrane have proved virtually incurable. He classifies with the bullous processes all those disorders that appear in the form of large or average bullae in the buccal and palatal mucous membranes. The bullae burst readily and the roundish, readily bleeding foci of the mucous membrane frequently merge, so that considerable areas of the mucous membrane are denuded of epithelium. The bullous stage is not often observed, but remnants of the burst foci are occasionally seen. Improvements and exacerbations alternate, but there is never a complete cure. After discussing the differentiation from erythema exudativum multiforme, pemphigus, ulcerous stomatitis and allergic bullous disorders of the mucous membrane usually caused by certain medicaments, the author gives the clinical history of a man, aged 78, who, in addition to a severe angina pectoris, had a bullous exanthem on the chest, the left leg, the inguinal region, the scalp, the nostrils, the pharynx and the palate. The oral bullae ruptured and swallowing became difficult. Since painting with a 1 per cent solution of acriflavine hydrochloride was of slight benefit the author resorted to oral liver therapy. At first a liquid preparation was given and later natural liver. Under the influence of this treatment the patient's general condition improved noticeably and after several weeks the oral symptoms had entirely disappeared. The author cites another case that took a similar course, and he recommends a trial with liver preparations in the bullous exanthems and enanthems of the mouth, the skin and the nose. The lesions of the mucous membrane should either be left alone or should be painted with a 1 per cent solution of acriflavine hydrochloride. Corrosives are injurious and should be omitted.

Histopathology of Sclerocystic Ovaries E. E. Gigowsky—p 226

**Habitual Hydramnion**—Beaufays reports the history of a woman, aged 35, who had been pregnant six times. The first pregnancy ended normally. During the second pregnancy she developed edema, and the child died two days after the delivery. The following pregnancy terminated with the birth of a macerated fetus. During this pregnancy the woman again had severe

edemas and she stated that on rupture of the bag of waters an unusually large amount of fluid had been passed. During the fifth pregnancy the woman was first seen in the author's clinic. On admission she showed severe edema. The protein test of the urine was weakly positive and the sugar test was negative. The blood pressure was 145 mm of mercury. The edemas disappeared after several days of a special diet and of limitation of fluid intake. The blood pressure decreased likewise. Fetal movements and heart sounds were not perceptible. After the death of the fetus had been established, delivery was induced. A macerated fetus was born and large amounts of greenish amniotic fluid were discharged. During the sixth pregnancy there were no edemas during the seventh month, but the patient's abdomen was already of considerable size and the urine again contained protein. The condition was diagnosed as nephropathia and hydramnion. At her request she was discharged from the clinic, but she was ordered to keep a strict diet and rest in bed. She returned to the clinic after one month, complaining of nausea and vomiting. The circumference of the abdomen had increased and respiration was difficult. The fetal movements had ceased. Delivery was induced and on the rupture of the bag of waters, 3,300 cc of greenish fluid was discharged. The fetus was macerated but its necropsy revealed no abnormality. The placenta was unusually large. Repeated tests had never revealed signs of syphilis. The author reviews the literature on habitual hydramnion. Reports of the habitual form are rare. The following factors have been cited as causes: (1) on the part of the mother: placenta praevia, large placentas and nephropathia of pregnancy; (2) on the part of the fetus: repeated occurrence of hydrocephalus or of dropsy and changes in the umbilical cord. The children are always born dead and macerated, but death of the mother is mentioned only in the case of placenta praevia. Nothing definite is known about the etiology.

**Hypophyseal Plethora (Cushing's Disease Pituitary Basophilism)**—Jamin describes a case of the syndrome (obesity, osteoporosis, genital hypoplasia, hypertension and adynamia) that Cushing ascribes to the basophil adenoma of the anterior lobe of the hypophysis. The author emphasizes that circulatory disturbances, acrocyanosis, angiospasm and hypertension play a determining part in the syndrome, and for this reason he suggests the term "hypophyseal plethora" as an antithesis to the term "hypophyseal cachexia." He points out that the disease is the manifestation of an endocrine hyperactivity of the adenohypophysis. This hyperfunction is to be differentiated from the effects of the growth hormone, for it is rather the result of an excessive, unchecked hypophyseal stimulation of subordinate endocrine glands, particularly of the suprarenals, the posterior lobe of the hypophysis and the parathyroids, which becomes manifest as a pluriglandular disturbance involving the appearance as well as the functional activities of the organism. High voltage roentgen irradiation has been known to influence the syndrome favorably. The endocrine hyperfunction is probably the result of adenomatous or diffuse proliferation of the basophil elements of the adenohypophysis.

**Treatment of Asthenia**—Backmund calls attention to the treatment of asthenia by means of Bucky's borderline rays. He abandoned Bucky's original method of generalized irradiation and gave instead eight irradiations on eight different fields. Each field receives 300 roentgens. The rays are applied by means of a borderline ray apparatus. The focal distance is 15 cm., the strength of the current 10 milliamperes and the tension 9 kilovolts. The dose of 300 roentgens (measured in the air) produces a temporary erythema but rarely, after from one to two weeks however, a pigmentation often becomes visible and persists for longer periods. The author

employed the borderline ray treatment in thirty-five cases manifesting the signs of the hypotonic syndrome. The treatments were given in the course of a sanatorium cure (generally of three weeks' duration). In addition to the borderline ray therapy the patients received only the usual physical and dietary treatment. The borderline ray therapy increased the low blood pressure, the low blood sugar and the basal metabolism. The vasomotor and dyskinetic disorders disappeared and the general condition improved. In discussing the action mechanism of borderline ray therapy in asthenia the author expresses the opinion that its efficacy is due to the modification of the sympathetic nervous system by way of the skin, for in the asthenic person the regulation of this system is disordered.

\*Generalized Xanthomatosis K Herman—p 1100

**Simple Method for Demonstration of Protein in Urine**—Wahl emphasizes the importance of sulphosalicylic acid in the demonstration of protein in the urine and describes a new simple method that employs a specially prepared paper as a reagent. The paper can be prepared by the practitioner in the following manner. A piece of blotting paper is placed on a piece of glass and is saturated with a 20 per cent solution of sulphosalicylic acid. After the fluid has evaporated, the blotting paper is cut into strips 7 by 0.5 cm. A small bundle of these strips is carried by the physician. In order to effect flocculation of the protein contained in a specimen of urine, it is sufficient to dip a strip of the paper into it. The paper is a highly sensitive reagent, by means of which a protein content of less than 0.025 per cent can be detected. The paper may be kept for a long time several months of exposure to light and air did not impair its efficacy.

**Removal of Needle from Lung by Incision**—Lebsche advises that needles that have penetrated into the deeper air passages and cannot be removed by means of bronchoscopy be removed by incision into the chest. The dangers of the intervention have been reduced since bronchotomy has been replaced by pneumobronchotomy. Sauerbruch advises the same procedure for removal of foreign bodies from the bronchi as he does for the removal of bullets from the lung. The thoracic cavity is opened widely, the lung collapses and the foreign body can be felt. The surgeon holds the region of the foreign body with the left hand and makes the necessary incision to remove the foreign body. Blood, mucus and pus are removed, the wound is dabbled with iodine and then carefully closed with several button sutures. Lung and pleura are sutured in two or three further layers, and the thoracic wall is closed under differential pressure. The author maintains that the dangers of this method are comparatively slight. He describes two cases. One report proves that the outcome of the intervention is largely determined by the localization and course of the accompanying inflammation. The second case shows that postponement makes the treatment more difficult.

**Generalized Xanthomatosis**—Herman maintains that generalized xanthomatosis is essentially an infiltration of the various organs with cells containing cholesterol. The process produces a granulation tissue and for this reason is referred to also as lipoid granulomatosis. Deposits of keratin or of phosphatides, respectively, produce Niemann-Pick's disease and Gaucher's disease. Deposits of cholesterol produce xanthomatosis. Schüller-Christian's disease is not a disease entity but belongs to the group of xanthomatoses. The author gives a detailed description of the clinical history of a woman who had a generalized xanthomatosis. The diagnosis proved difficult for the patient had diabetes insipidus, xanthoma of the eyelids and ulcerous lesions of the skin and the cholesterol content of her blood was greatly increased. The latter factor finally decided the diagnosis of generalized xanthomatosis.

Spontaneous Cure of Renal Tuberculosis? R Chwalla—p 882  
Alleviation of Pain in Obstetrics W Weibel—p 884

**Traumatic Fatal Shock**—Herbst shows that the circulatory disturbances produced by traumas not causing tissue injuries are nervous vascular crises, which, according to the circumstances, produce different changes in the periphery. He rejects a differentiation between shock and collapse and applies the term shock to all traumatic circulatory crises. However, he differentiates purely traumatic from wound shock and points out that there is also an ethetic form of traumatic shock. On the basis of a case of shock ending fatally, he discusses the various manifestations that are possible in case of traumatic shock and also its genesis and therapy.

**Significance of Specific Dynamic Protein Action**—Hogler calls attention to the reports of investigators who recommended the determination of the specific dynamic protein action as a differential diagnostic aid in endocrine, particularly hypophyseal, disturbances. Another group of workers pointed out that the specific dynamic protein action not only is dependent on the state of the endocrine system but is influenced by the rapidity of the evacuation of the stomach and by the speed of the resorption. The author's studies disclosed that the secretory activity of the stomach plays a part. He found that the specific dynamic action may be reduced in cases of hypoaecidity or of anaecidity. However, the specific dynamic protein action can almost be normalized in these persons by administering larger quantities of hydrochloric acid-pepsin. The fact that this was possible even in a hypophyseal dwarf shows that disturbances in the gastric secretion may weaken or suspend the specific dynamic action in persons with or without endocrine disturbances. Further studies revealed that even the preparation of the food influences the specific dynamic protein action. The author reaches the conclusion that the determination of the specific dynamic protein action may aid in the differential diagnosis of endocrine disorders only if disturbances in the gastro-intestinal function can be excluded.

**Blood Pressure and Posture**—Rudsit studied the blood pressure in the reclining, sitting and erect positions. With the change in position he observed among the examined persons three distinct types of blood pressure reactions, but he detected no relation between the reaction and the disorder existing in the examined person. Of the three types observed, he attaches the greatest significance to that one in which the blood pressure is lower in the erect than in the reclining position. Persons in whom this type of blood pressure reaction is most pronounced have severe vasomotor disorders on the basis of an endocrine disturbance. The author describes five cases of vasoneurotic disturbance and shows the favorable influence produced by preparations of the anterior lobe of the hypophysis. The improvement in the subjective symptoms was accompanied by a reversion from the pathologic to the normal blood pressure reaction.

- Closure Reimplantation and Inflation of Uterine Tubes While Abdomen is Open L Fraenkel—p 1634  
\*Abortion Between Two Periods K Heim—p 1641  
Semmelweis and Modern Bacteriology K Burger—p 1649  
\*Diagnosis of Interstitial Pregnancy F Drazancic—p 1653

**Abortion Between Two Periods**—Heim points out that the question as to whether menstruation may still take place following impregnation of the ovum has been answered variously in recent times. After reviewing some of these contradictory opinions he gives the detailed description of a case in which it could not be doubted that following impregnation, that is, during pregnancy, a normally profuse menstrual bleeding occurred. The woman menstruated regularly after intervals of twenty-five or twenty-six days. The last menstruation (in February) did not essentially differ from the preceding one. On the twelfth

day after this menstrual period the woman observed an almost negligible discharge of blood, but, since she had had this intermenstrual discharge occasionally in former years, it was interpreted as a manifestation of ovulation. However, two days later there occurred an unusually profuse discharge of light red blood. In the course of this bleeding a formation the shape of a lentil was discharged. The histologic examination of the lentil shaped body revealed embryologic structures. The subsequent development of the woman's cycle was normal, for a regular menstrual bleeding set in on the end of the twenty-fourth day after the last menstruation. Of especial significance is the outcome of the Aschheim-Zondek test on the urine that was evacuated ten hours after the expulsion of the embryo. This urine produced in infantile mice reactions I (follicle maturation) and III (formation of corpus luteum). Reaction II was only microscopically perceptible in the form of incipient follicular bleedings in two animals. This outcome of the Aschheim-Zondek test corroborates the diagnosis of early abortion. The author is not quite certain about the age of the ovum, but on the basis of available data he assumes that impregnation took place approximately three weeks before the expulsion. After attempting a theoretical explanation of the menstruation after the impregnation, he reviews a case that somewhat resembles the described one and then calls attention to the eventual forensic significance of these observations.

**Diagnosis of Interstitial Pregnancy.**—Dražanac maintains that the diagnosis of implantation of the ovum in the intramural portion of the tube, as well as that of advanced interstitial pregnancy, usually encounters great difficulties. This is due to the fact that this form of ectopic implantation of the ovum may become manifest with such variable symptoms. As a rule, the interstitial pregnancy perforates suddenly in the third or fourth month, so that an immediate operation becomes necessary and there is no opportunity for observation. However, there are certain symptoms of interstitial pregnancy that some observers have detected. The author mentions the broad-based connection of the ovisac with the uterus, which was described by Baart de la Faille and the so called Ruge-Simon sign, namely, the nearly vertical sloping of the fundus uteri. Nevertheless, cases have been reported in which Ruge-Simon's sign was missing. The author describes a case in which, in addition to the two signs mentioned, he observed another symptom that he considers characteristic for interstitial pregnancy, namely, a free mobility of the section of the tube containing the interstitial pregnancy, which is independent of that of the uterus. A review of the literature revealed that Zimmerman likewise had observed this sign. He thinks that the three signs may aid in the early diagnosis of interstitial pregnancy and also in its differentiation from ovarian tumors and subserous myomas.

**Agranulocytosis Due to Medicaments.**—Groen and Gelderman sought to determine what drugs were used by patients who were treated for agranulocytosis. Of thirteen cases observed during the last three years, neoarsphenamine was a causative factor in two. Nine patients had been taking some drug containing antipyrine or amidopyrine, often in combination with some other compound, before the onset of their symptoms. In one case recovery of the number of leukocytes and of the necrotic angina was observed after discontinuance of the amidopyrine medication. In two cases an inquiry among the physicians who had been treating the patients before their admission revealed only the use of acetylsalicylic acid sodium salicylate and quinine sulphate, but the possibility that other drugs had been taken could not be excluded. Five additional cases, observed elsewhere, are described. In each case some compound containing amidopyrine had been used. The authors maintain that an outbreak of agranulocytosis may follow the use of various drugs. Among those antipyrine and amidopyrine

have a definite etiologic significance. The possibility of a similar effect of other antipyretics and hypnotics (especially the two barbiturates) must be borne in mind. The danger of an agranulocytotic syndrome occurring after the use of drugs is probably restricted to certain allergic individuals. Many present conceptions about agranulocytosis must be revised, a toxic etiology of agranulocytosis appears to be the rule rather than the exception. During the administration of antipyrine or amidopyrine, a continuous supervision of the leukocyte count is imperative.

**Alcoholic Intoxication and Accidents.**—Hindmarsh and Linde report a study of alcoholic intoxication in accident cases admitted for the past year to the surgical clinic in Stockholm. The clinical examination was supplemented by Widmark's micromethod of determination of alcohol in the blood. The results of clinical examination approximated rather closely those of blood examination. The authors emphasize that one should refrain from rendering an opinion as to inebriety in severe injuries. The incidence of accidents while under the influence of alcohol is quite high. It is not uncommon to find in men injured while at work that a considerable amount of alcohol has been consumed. Of 283 male patients admitted to the hospital because of injuries sustained in an accident, 41 per cent were found to have alcohol in the blood. Those injured in traffic showed about the same rate. Accidents while under the influence of alcohol were most frequent among elderly people. The number of accidents tends to increase over week ends and during bank holidays. More than half of those who have overturned while driving an automobile or a horse, as well as pedestrians who were knocked down, had alcohol in their blood. This supports the view that not only the driver of the vehicle but the injured person as well should be examined for inebriety.

**Blood Changes After Gastric Resection.**—Dedichen studied blood alterations in a group of 164 patients in whom a partial gastric resection was performed and, for comparison, in another group of nineteen patients in whom only a gastro-enterostomy was performed. In the first group eighty-three, or about 50 per cent, developed anemia, while in the second group only three developed a mild degree of anemia. The average hemoglobin reading (Sahli) in the latter group was 92 per cent, a much higher figure than that obtained in the former. The tendency to anemia was much greater in women than in men. Thus of ninety-three men, twenty-five, or 27 per cent, developed anemia, while in a group of seventy-one women there were found fifty-eight, or over 80 per cent with anemia. Of women whose age was below 40, only one failed to show anemia. The hemoglobin was as low as 24 per cent (Sahli) in some of the cases. Two men showed distinct symptoms of pernicious anemia. Comparison with Faber's figures on the incidence of anemia in cases of spontaneous achylia indicated that the tendency was greater in achylia following gastric resection. Anemia may likewise develop after a gastric resection in the absence of achylia. Thus it appears that achylia is not the sole factor of importance in the development of anemia after resection. The author considers that, if the views regarding the hematopoietic significance of the stomach are correct, an extensive resection may be a contributing factor. The results of his gastric analyses showed that four out of 107 had free hydrochloric acid. Complete achylia does not take place even after extensive resection, owing possibly to the presence of some pyloric glands in the fundal mucosa. The rapid emptying of the stomach after resection with the resultant abnormal stress on the function of the upper jejunum may be another contributing factor in anemia. In selecting the operation for a gastric ulcer, particularly in a young woman, one should take into account the tendency to anemia.

## THE DIAGNOSIS AND TREATMENT OF THE IRON-DEFICIENCY ANEMIAS

FRANK H. BETHELL, MD  
S. MILTON GOLDHAMER, MD  
RAPHAEL ISAACS, MD  
AND  
CYRUS C. STURGIS, MD  
ANN ARBOR, MICH

A lack of sufficient iron available for the requirements of hemoglobin formation leads to anemia of the hypochromic or "secondary" type. Such an anemia may properly be attributed to iron deficiency, even though this element is supplied in usual quantities in the diet.

The most frequent cause of iron-deficiency anemia is continued or recurrent excessive loss of blood. The replacement of hemoglobin lost by hemorrhage depletes and finally exhausts the body's reserves of iron.<sup>1</sup> In such cases the dietary iron is insufficient for the increased demand, and anemia results.

A "secondary" anemia, occurring most often in middle-aged women, and frequently not associated with excessive loss of blood, has recently attracted a great deal of attention. Its commonly accepted designation is idiopathic hypochromic anemia.<sup>2</sup> Achlorhydria or marked hypochlorhydria is an invariable accompaniment of this condition. The anemia is presumably due to defective absorption of dietary iron, dependent on the lack of acid in the stomach. However, in the normal individual the conservation of iron is so efficient and in the adult the requirement of food iron so small that, even in the presence of achlorhydria, anemia rarely develops unless there is an additional factor,

such as blood loss or pregnancy.<sup>3</sup> It appears that, in some women with achlorhydria, normal menstruation results in sufficient loss of blood to cause anemia.

Anemia due solely to a lack of iron in the food occurs most commonly in infants and young children.<sup>4</sup> It may develop in elderly persons living on grossly abnormal diets, although in these cases vitamin deficiency also probably plays an important role.<sup>6</sup>

The term "iron-deficiency anemia" is based on etiological considerations with their therapeutic implication and in no sense denotes a constant clinical entity. The symptoms and physical signs associated with this condition are those of any anemia and comprise fatigability, weakness, faintness, dizziness, palpitation, dyspnea on exertion, pallor, tachycardia, hypotension and dependent edema. Some patients with achlorhydria complain of difficulty in swallowing (Plummer-Vinson syndrome), caused apparently by esophageal spasm. Enlargement of the spleen is sometimes present.<sup>6</sup> In a considerable number the clinical picture bears a certain resemblance to that of pernicious anemia. There may be recurrent glossitis with subsequent atrophy of the papillae of the tongue. Digestive disorders consisting of anorexia, distention, flatulence and alternate constipation and diarrhea are not uncommon. Some patients complain of numbness and tingling of the extremities, although objective neurologic changes have not been reported.

Of thirty-three patients having hypochromic anemia with achlorhydria studied at the Simpson Memorial Institute, five mentioned dysphagia as one of their most troublesome symptoms, thirteen patients complained of periodic soreness of the tongue and mouth, six had paresthesia of the extremities.

The sex, age and duration of anemia of twenty-seven patients with acid gastric secretion and of thirty-three patients with an acidity studied consecutively are shown in charts 1 and 2. Of the latter

group all but two were females, their average age was 42.9 years, and 85 per cent were known to have been anemic for more than three years. In contrast, the group secreting hydrochloric acid showed a slight predominance of males, their average age was 33.3 years, and 78 per cent had been anemic for less than three years.

Chart 1—Sex and age of patients with iron deficiency anemia

In conjunction with the routine blood count, the estimation of erythrocyte size is of great importance in the study of iron-deficiency anemia. The measurement of cell diameters, on stained blood films, according to the method of Price-Jones, makes possible the determination of the mean diameter and gives information regarding the percentage distribution of cell sizes. The use of the hematocrit in conjunction with the erythrocyte count affords a more delicate method of measuring cell size, as it deals with volume rather than with diameter, but it fails to differentiate variations of corpuscular volume in any given blood sample. It is a characteristic of the form of anemia under consideration that together with the decrease in corpuscular hemoglobin there is, but to a relatively less degree, a diminution of cell size. Thus the color index, mean erythrocyte diameter, volume, hemoglobin and hemoglobin concentration are all lowered.<sup>7</sup> When there has

Chart 2—Duration of symptoms of anemia

been recent and relatively acute hemorrhage, these values are less characteristic and the red blood cells may vary but little from normal. A group of cases in

which these determinations were made is shown in table 1.

The blood examination of patients with iron deficiency reveals a secondary type of anemia of all grades of severity. In contrast to the low hemoglobin, the red blood cell count, in long-standing cases without recent acute hemorrhage, is usually within or near normal limits if the hemoglobin is above 7 Gm per hundred cubic centimeters. With lower hemoglobin values there is generally a progressive decline in the number of erythrocytes per cubic millimeter. In our series of cases the lowest blood count was found in a woman, aged 36, with achlorhydria and without a history of an abnormal loss of blood. The red blood cell count was 1,920,000 per cubic millimeter, the hemoglobin 1.83 Gm per hundred cubic centimeters (11 per cent). After five weeks of treatment with iron the erythrocyte level was 4,420,000 per cubic millimeter, the hemoglobin 8.13 Gm (49 per cent) (chart 5). The range of the color index in these cases without recent hemorrhage is about 0.4 to 0.7. When there has been continued loss of blood the depression of the erythrocytes is more commensurate with that of the

\* Cases 1 and 2 presented severe continued bleeding shortly before the counts were made. The others showed long standing anemia for the most part with achlorhydria.

† Uncorrected.

‡ Expressed in micromicrograms.

hemoglobin, and the color index and mean erythrocyte volume are greater. In the latter type of case the first effects of treatment may result in a lowering of the color index, as the red blood cells regenerate at a more rapid rate than the hemoglobin. In one of our patients, a woman, aged 39, with a normal degree of gastric acidity, anemia developed as the result of bleeding hemorrhoids. The duration of the illness was at least one year. On admission the red blood cell count was 2,230,000 per cubic millimeter, hemoglobin 5.48 Gm (33 per cent), color index 0.74. After three weeks of treatment the erythrocytes numbered 4,450,000 per cubic millimeter, hemoglobin value 9.13 Gm (55 per cent), color index 0.62 (chart 6).

The estimation of the response to treatment of persons with iron-deficiency anemia depends on the clinical improvement and on characteristic changes in the blood picture. The earliest effect is commonly an increase in the percentage and concentration of reticulated red blood cells. As was pointed out by Minot and Heath,<sup>8</sup> there is an inverse relationship between both the erythrocyte count and the hemoglobin value at the beginning

7 These phenomena have been discussed by Price Jones C. The Variation in the Sizes of Red Blood Cells. Brit. M. J. 2 1418 (Nov. 5) 1910. Murphy W. P. and Fitzhugh Greene. 8 Minot G. R. and Heath C. W. The Response of the Reticulocytes to Iron. Am. J. M. Sc. 183 110 (Feb.) 1932.

of treatment and the height of the reticulocyte percentage response. However, the peak of the response in a given case of iron-deficiency anemia is much less predictable than in one of pernicious anemia, probably because the etiologic basis of the former type may vary so widely. Reticulocyte counts, on patients with secondary anemia treated with iron, are of clinical value only in that they indicate early in the course of therapy

normoblasts and macronormoblasts,<sup>9</sup> but it is probable that the obstacle to maturation operates at all stages of the developing erythrocyte. The accumulation of normoblasts may be the result of a general retardation of development of cells, poorly equipped from the outset for their functional role in the organism. The availability of additional iron probably accelerates erythrocyte maturation from the beginning of the

whether or not the anemia will be benefited by iron or, in the case of a preparation of unknown value, they may yield information regarding its potency.

Reticulocytosis in iron-deficiency anemia is explained by the apparent stimulatory effect of this element on erythrocyte maturation. In that iron is lacking, a defect of blood formation may be considered to exist, even though the erythrocyte level in the circulating blood is not appreciably depressed. Bone marrow studies in this type of anemia reveal a large number of

process, the partially developed corpuscles being forced into the circulation by the pressure of antecedent activity. This hypothesis is supported by the clinical observation that, during the early period of the reticulocyte response, although there may be a gain in erythrocytes and hemoglobin depending on the influx of new cells, there is commonly little or no change in the

<sup>9</sup> Dameshek, Doan, C. A. Current Views on the Origin and Maturation of the Cells of the Blood. *J. Lab. & Clin. Med.* 17: 887 (June) 1932. Isaacs, Raphael. Mechanism of the Production of Anemia. *J. A. M. A.* 101: 2077 (Dec. 23) 1933.

color index or mean corpuscular hemoglobin. On the other hand, the appearance of immature and abnormal red blood cells in the circulation may, in part, result from the rapid "cleaning out" of the extramedullary centers of hematopoiesis commonly accompanying severe anemia.<sup>10</sup>

Observations on so limited a series of cases as is presented here does not justify detailed conclusions regarding the rate of increase of hemoglobin and red blood cells throughout the course of iron therapy. The response of forty-two patients treated orally with either 4 Gm of ferric ammonium citrate or 15 Gm of ferrum reductum daily, is shown in tables 2 and 3. The cases have been separated into those with and those without hydrochloric acid in the gastric contents. Histamine stimulation was used during each gastric analysis and for the present purpose, no distinction between degrees of acidity is made. All members of both groups had anemia with low color index. Cases of acute hemorrhage, continued bleeding during treatment, obvious infection, malignancy, nephritis and cirrhosis of the liver are not included. Most of the recorded observations were made while the patients were in the hospital and partaking of the usual house diet, from which liver and kidneys were excluded.

Erythrocyte counts were made with apparatus certified by the U S Bureau of Standards and hemoglobin estimations were done by a modified Sahli technic, the standard used being equivalent to 166 Gm of hemoglobin at 100 per cent, as determined by the oxygen capacity method. Included in the tables are the patients' ages, initial red blood cell counts in millions per cubic millimeter, initial hemoglobin values in terms of both percentage and grams per hundred cubic centimeters, and available weekly determinations of the hemoglobin with the consequent total gain in hemoglobin, the two latter values being expressed in grams per hundred cubic centimeters. The observations cover a maximum of eight weeks following the institution of iron therapy, but the greater number of patients were followed for a shorter time. Erythrocyte counts, except those taken at the first and last recorded

patients, which illustrate the characteristic types of erythrocyte response to iron in those forms of anemia amenable to its use.

By subtracting from the average total hemoglobin gain registered each week the average total gain at the preceding week, values are obtained that represent the average increase in hemoglobin, expressed in grams per hundred cubic centimeters, during each of the first eight weeks of iron therapy. These values are plotted

Chart 4—Comparative effect of 0.3 Gm and of 1.5 Gm of ferrum reductum given daily in three parts after meals to a patient with achlorhydria

Chart 3—Weekly average hemoglobin increase during treatment with iron preparations

observation, are not shown, because an effective correlation of the data involved is not possible without further subdivision of the groups, a procedure which the limited number of cases renders impractical. The patients were selected for the present report primarily on the basis of their hemoglobin deficiency, and they comprise a very wide range of erythrocyte values. On charts 4, 5 and 6 are recorded, in association with other data, successive red blood cell counts made on individual

in the form of histograms (chart 3). It should be noted that the rate of increase of hemoglobin during the first three weeks of treatment is appreciably greater in those patients who secrete hydrochloric acid into the stomach than in those with achlorhydria. Recovery from anemia is attained sooner by the members of the former group, but the ultimate results of treatment with iron are equally satisfactory in the two groups. The values for weekly gain, taken in conjunction with the weekly average hemoglobin totals, compare favorably with the results reported from the use of iron and copper,<sup>11</sup> iron and "secondary anemia liver extract,"<sup>12</sup> iron and intramuscular liver extract,<sup>13</sup> and iron and desiccated stomach.<sup>14</sup> The apparent value of whole liver with supplementary iron in the treatment of anemia associated with malnutrition and vitamin deficiency<sup>15</sup> can probably be attributed to its protein and high content of vitamins A and B rather than to any specific hematopoietic substance.<sup>16</sup>

With reference to the value in iron-deficiency anemia of supplying erythrocyte "stroma building substances," it is of course conceivable that in some patients with achlorhydria and simple anemia there may be a diminished production of the intrinsic factor shown by Castle<sup>17</sup> to be essential for erythrocyte maturation. Such patients might be expected to benefit from the administration of liver, liver extract or desiccated stomach in conjunction with adequate amounts of iron. However, the fact that there is usually little or no increase in the color index during the most active period of blood regeneration in response to iron, and that the color index rarely attains unity before the count becomes normal indicates that in the great majority of patients with iron-deficiency anemia there is no dearth of stroma building material.

Evaluation of therapeutic iron preparations will not be attempted in the present report, since in the treatment of iron-deficiency anemia our aim has been to achieve maximum absorption and utilization of iron by administering the metal in excess quantities.<sup>18</sup> Iron in a soluble salt is apparently more efficiently utilized than the same quantity as ferrum reductum, but the latter will produce equally good results if given in adequate dosage and possesses the advantages of small bulk and comparative freedom from irritative effects on the

for daily administration, and in these dosages the two forms of iron are quite comparable in their effects. Continued iron medication is usually necessary in order to prevent recurrence of anemia in patients with achlorhydria. Apparently there is less tendency for relapse to occur after the menopause.

That relatively large quantities of iron are required by the patient with achlorhydria is illustrated by the blood studies depicted in chart 4. J. A., a woman,

Chart 5—Effect of 0.3 Gm of purified ferrum reductum given daily in ten doses hourly of 0.03 Gm to a patient with achlorhydria

alimentary tract. In our experience 4 Gm of ferric ammonium citrate, representing about 0.8 Gm of iron, or 1.5 Gm of ferrum reductum, is an optimum amount

Chart 6—Effect of 0.3 Gm of purified ferrum reductum given daily in three parts after meals to a patient with normal gastric acidity

aged 45, received 0.1 Gm of ferrum reductum three times a day for fourteen days. There was no definite reticulocyte response or increase in the red blood cells or hemoglobin. When the dosage was augmented to 0.5 Gm three times a day a prompt effect was noted. That this increase was not due to a delayed response to the preceding small dosage of iron is indicated by the behavior of the reticulocytes, which followed a characteristic course during the second period of treatment. It is probable that the time of administration of iron and the division of the daily dosage are factors almost equal in importance to the total amount given to patients with achlorhydria. Mettler and Minot<sup>19</sup> have shown that iron is absorbed more rapidly from an acid than from an alkaline medium.<sup>20</sup> Our patients received their iron immediately after each meal, when the gastric contents presumably were at the greatest degree of acidity. Of physiologic interest is the observation, recorded in chart 5, that a daily quantity of iron, ordinarily ineffective in the presence of achlorhydria when given in the usual three doses, is markedly efficacious when administered in relatively minute amounts hourly throughout the day. The patient in question, M. D., a woman, aged 36, received 0.03 Gm of ferrum reductum ten times a day, the same

total amount as that first given to J A, which in her case failed to induce a response. A definite reticulocyte response and a sustained rise of erythrocytes and hemoglobin were obtained. It would seem that a larger proportion of the iron ingested is absorbed when the metal is allowed to pass through the alimentary tract in an almost continuous stream than when administered in more concentrated doses. That such considerations are not valid for patients with normal gastric secretion is indicated by the response of the blood in the case of a woman, M M, aged 39, who received 0.3 Gm of ferrum reductum given daily in three parts. Here the presence of hydrochloric acid has made possible a more efficient utilization of the iron than occurred in the two previously described cases of anacidity (chart 6).

In order to exclude, so far as could be done, the possible effect of copper on blood regeneration in iron-deficiency anemia, a number of our patients were treated with minimal effective amounts of ferrum reductum, especially prepared and purified so as to contain less than 0.001 mg of copper per gram of iron. Furthermore, for at least one week prior to treatment and throughout the course of iron therapy such patients received a diet supplying approximately only 0.5 mg of copper daily. The usual diet supplies about 4 mg of copper daily. The two patients M D and M M, whose blood records are depicted in charts 5 and 6, were treated in this manner. The low copper intake apparently made no difference in the responses of these patients to iron. While such observations do not take into account the possible influence of copper already stored in the body, they suggest that in the treatment of the usual case of iron-deficiency anemia, whether or not associated with achlorhydria, no advantage is gained by including copper in therapeutic preparations of iron.

#### CONCLUSIONS

Iron-deficiency anemia results from a lack of sufficient available iron for normal hemoglobin formation. Such a lack may be induced by (1) depletion of the iron reserves from continued blood loss, (2) inadequate intake of food iron and (3) improper absorption of the element from the alimentary tract and, as a rare possibility, (4) from inability to utilize available iron.

In women with achlorhydria, anemia may develop as the result of the physiologic loss of blood. In such cases a "conditioned deficiency" dependent on the lack of hydrochloric acid may be said to exist.

The clinical features presented by patients with iron deficiency anemia are not specific. They include the effects of lack of hemoglobin supplemented by the manifestations of whatever associated condition may be present. By contrast, the blood in such patients possesses certain definite characteristics that are of diagnostic value. The relative decrease of hemoglobin exceeds that of the erythrocytes, and the average size of the red corpuscles is reduced, although proportionately to a less extent than the diminution of hemoglobin. Consequently, the color index and the mean erythrocyte diameter, volume, hemoglobin and hemoglobin concentration are below normal.

The effects of treatment with simple iron preparations of forty-two cases of iron-deficiency anemia, twenty-eight with achlorhydria, are shown in tabulated form. These results compare favorably with those reported by others employing combinations of iron with other substances in the treatment of the same type of anemia.

Relatively large amounts of ingested iron are required for satisfactory clinical and hematologic improvement. Ferrum reductum, 1.5 Gm daily, or ferric ammonium citrate, 4 Gm daily, administered in three divided doses after meals, in our experience, is therapeutically optimal. Following the institution of treatment a latent period, during which no change in the peripheral blood picture occurs, is attributed to the time required for maturation of the primitive erythrocytes in the bone marrow. In general, the blood of patients with acid gastric secretion responds more promptly to iron medication, and a smaller dosage of the element is required than is the case of those with achlorhydria. In both groups the erythrocyte and hemoglobin values are usually restored to normal after from six to eight weeks of therapy. Patients with achlorhydria often require continued treatment with iron in order to prevent recurrence of anemia.

Administration of highly purified ferrum reductum in conjunction with a "low copper" diet did not detract from the efficacy of the iron, as evidenced by the rate of hemoglobin formation.

### ASSAY OF COMMERCIAL EXTRACTS OF LIVER FOR PARENTERAL USE IN PERNICIOUS ANEMIA

#### METHOD OF SUCCESSIVE RETICULOCYTE RESPONSES IN THE SAME PATIENT

WILLIAM DAMESHEK, MD

AND

WILLIAM B CASTLE, MD

BOSTON

Much water has run under the bridge since the report in 1926 by Minot and Murphy<sup>1</sup> that a hitherto fatal disease, pernicious anemia, could be effectively treated by the use of large amounts of liver. The preparation of an effective fraction or extract of liver was soon announced by Cohn, Minot and their associates.<sup>2</sup> Since 1927, various commercial extracts have been available for clinical use. These have been in the form of a simple aqueous concentrate or as the material soluble in 70 per cent but insoluble in 95 per cent alcohol (fraction G of Cohn), prepared as a powder or in water-alcohol solution. Lately this fraction has been prepared in aqueous solution suitable for parenteral administration. The organs of a variety of animals have been used: the cow, the sheep, the pig, the horse, and even the codfish. After the discovery that pernicious anemia was a disorder usually dependent on defective gastric secretion,<sup>3</sup> Sturgis and Isaacs,<sup>4</sup> in collaboration with Sharp,<sup>5</sup> used the desiccated and defatted

gastric tissue of swine in its treatment. As another by-product of the experimental observations on the hematopoietic effects of the interaction of beef muscle with normal gastric juice has come "extralin," which is prepared by the interaction of liver or liver extract with fresh hog gastric tissue.<sup>6</sup>

The clinician faced with a patient having pernicious anemia has lately been in the rather pleasant position of choosing one of the several effective extracts rather than of attempting to decide on a medication that might be of possible value. Recently the use of the parenteral extracts has been in the ascendency. Gansslen<sup>7</sup> in 1930 was the first to prepare an extract suitable for intramuscular use. Castle and Taylor<sup>8</sup> in 1931 and Strauss, Taylor and Castle<sup>9</sup> in the same year reported the successful preparation of extracts suitable respectively for intravenous and intramuscular use from an already available extract for oral use (fraction G of Cohn et al.). It was soon found that material given by the parenteral route was at least thirty times as effective as when given by mouth, since the same results could often be accomplished by giving parenterally the material derived from 10 to 20 Gm. as from 300 to 600 Gm. of liver given orally. Various investigators, particularly Murphy,<sup>10</sup> soon pointed out that the parenteral method was more regular in its effectiveness, less expensive to the patient, certainly easier to tolerate than continued oral administration, and more amenable to careful supervision of the patient by the physician.

The first parenteral extracts proposed contained a relatively small amount of extract (20 cc. of solution contained the material derived from 100 Gm. of liver), but attempts at concentration were soon made. Then certain companies produced extracts in which as much of the material as possible derived from 100 Gm. of liver was dissolved in 5 cc. of liquid, later in only 3 cc. of fluid.<sup>11</sup> Another company produced an extract of equine liver suitable for subcutaneous or intramuscular usage which contained material derived from 100 Gm. of liver in 10 cc. of fluid.<sup>12</sup> There has been much vagueness in the phraseology descriptive of the various products, so that it has frequently been most difficult for the practicing physician to choose the most efficient and economical source of active material. The probability, furthermore, that some loss of potency would take place during preparation and especially during concentration has not been commented on in the literature regarding these products.

Even in the 1934 edition of *New and Nonofficial Remedies* no information regarding these questions is available. Therein, several liver preparations for parenteral use (and for that matter for oral use) are described as being derived from and also representing the antianemic potency of the original amount of liver used in their preparation.<sup>1</sup> Since it is known that the fraction used as the starting point in the preparation of most of the parenteral products has already sus-

tained a loss of 35 per cent of the original potency of the whole liver, one or the other of the foregoing statements must be in error. Judging from the observations of Cohn<sup>13</sup> and of West,<sup>14</sup> even more serious would be the losses of potency likely to occur in attempts at further purification or concentration of the material. Fortunately the effectiveness of active material given by injection is so much greater than when given by mouth that a relatively inefficient process of preparation would still give reasonably good clinical results with the large dosage usually advocated. Since little if any attempt has been made to determine the smallest dose of the different extracts necessary to produce a maximal hematopoietic response, it was considered desirable to attempt a comparative assay of various commercial (parenteral) extracts of liver on that basis.

#### METHODS AND MATERIAL

The various extracts of liver on the market must at present be tested on the human subject, since no suitable animal method for standardization has yet been found. The usual method is to test a batch of extract by observing its effect, when given in fairly large dosage, in increasing the numbers of reticulocytes and red blood cells in a group of patients with pernicious anemia. Average results are then computed. However, the scarcity and variability of suitable patients renders such observations less satisfactory than a comparison of effective materials in the same patient. Furthermore, unless submaximal dosage is used, losses of potency will not be detected unless the amount of active principle is reduced so greatly that a maximal reaction is not obtained. For these reasons, the method of investigation described here depends on the use in individual patients of comparative ten to fourteen day periods, during each of which the daily injection of a uniform suboptimal dose of a given product is carried out and the reticulocyte (and erythrocyte) responses are studied.

Suboptimal doses must naturally be used in a comparative study in the same patient, since, if optimal or maximal doses are used, a maximal response will usually be obtained, thus making subsequent responses impossible. Castle and his associates<sup>9</sup> had previously shown that a maximal reticulocyte response could be obtained following the daily intramuscular injection of as much of the amount of Liver Extract-Lilly, N N R, derived from 10 Gm. of liver, as could be dissolved in 2 cc. of water. Our comparative observations were therefore usually based on the daily injection of the amount of extract in various products derived from 5 Gm. of liver. When a suboptimal dose of liver extract is given a shower of reticulocytes roughly proportional to the amount of extract given is obtained. The reticulocyte "peak" is definitely lower than when a maximal dosage is given and may not be followed by a significant rise in the red blood cell count. However, the door is left open for further testing.

When a uniform daily suboptimal dosage of liver extract has been given, the reticulocyte response is either completely concluded in from ten to twelve days or is definitely on its downward course. This allows for the observation of a possible second response of reticulocytes when another more potent extract or a larger dosage of the same extract is given in a similar fashion. Not only has the principle of the "double" response, in determining whether a given form of therapy is maximal, been utilized in macrocytic anemia

by Minot and his associates<sup>15</sup> but Heath,<sup>16</sup> Dameshek<sup>17</sup> and others have used this method in the determination of the optimal dosage of various preparations of iron in the treatment of the hypochromic anemias. The conditions of our observations are thus sufficiently established to make it certain that, if a uniform suboptimal amount of active principle is administered daily until the reticulocytes have reached and declined from the peak of their rise, a second response in reticulocytes will take place only if the potency of the second material given is greater than that of the first. Moreover, under these conditions a greater potency of the second substance is demonstrated if this second response in reticulocytes is greater than, equal to or even less than the first. If the potency of the second substance is not sufficiently greater than that of the first, no second reticulocyte response whatever will appear. Daily injections must be used since, if only one, even very large, injection is given and is not followed by another for several days, a second reticulocyte

Hemoglobin and red blood cell counts were performed at least twice weekly, and frequently more often.

The injections were usually given deeply into the deltoid muscle, at times in the gluteal muscle. The volume of the extract to be given was carefully measured in a tuberculin syringe and then diluted to 1 cc with physiologic solution of sodium chloride or distilled water before injection. After from ten to fourteen days of the daily injection of a uniform dose of one type

Summary of Results of Reticulocyte Responses with Dilute and Concentrated Liver Extracts for Parenteral Use in Pernicious Anemia

A number following the letter for an extract denotes the amount of extract given in terms of the original weight of liver from which it is derived

response can be obtained after a short period (from five to ten days) with an identical amount of active material. The stimulus to the bone marrow must therefore be continuously applied during the estimation of the comparative potency of each product.

Satisfactory observations in ten patients with classic addisonian pernicious anemia were made in a study of four different extracts. The patients either were in their first relapse or had been subject to one or more relapses. A basal diet containing no liver and but little meat was used. The erythrocyte counts at the beginning of the assay varied from 780,000 to 2,000,000. Daily reticulocyte counts were performed. They were usually made with the "dry" method, a thin film of brilliant cresyl blue on a cover slip being used and counterstaining being done with Wright's stain.

Chart 1—Patient E S. Definite response in reticulocytes when the amount of concentrated extract B derived from 5 Gm of liver is given daily intramuscularly. When however dilute extract D is given daily in identical dosage a second even greater response in reticulocytes occurs, indicating that there has been loss of active principle in preparation of the concentrated extract. Patient C B. The procedure is reversed in this case: dilute extract D being given first. Note the lack of a second response when concentrated extract B is given in identical dosage. When the dosage of concentrated extract is greatly increased in a third period another response in reticulocytes occurs.

of extract, the patient was given a second type of extract derived from the same amount of liver. The study is still under way and is being somewhat modified at present by the attempt to determine if the amount of active material retained in one extract has been found to be greater than in another. This necessitates the use of different doses of different extracts in the same patient.

#### RESULTS

The liver extracts studied were in general of two main types "dilute" and "concentrated." The "dilute" type D contained the material derived from 100

Gm of liver dissolved in 20 cc of solution. The "concentrated" extracts were three in number B and C, two extracts containing the material derived from 100 Gm of liver in 3 cc of solution, and a third extract E containing the amount of material derived from

Chart 2—A response in reticulocytes occurs when the amount of concentrated extract B derived from 5 Gm of liver is given daily. However a second response occurs when another concentrated extract C is given in identical dosage indicating greater potency of the second concentrated extract. When dilute extract D is given in identical daily dosage in a third period a third response occurs indicating the greater potency of the dilute extract.

100 Gm of liver dissolved in 10 cc of solution. The results of the observations are summarized in the accompanying table.

Concentrated extract B was assayed in seven cases. In one of these cases (E S) the material (0.15 cc) derived from 5 Gm of liver was given daily for ten days followed by another ten-day period in which the amount of dilute extract D (1 cc) derived from 5 Gm of liver was given daily. A second reticulocyte response occurred, indicating that the dilute extract D derived from an identical amount of liver contained more of the active material than did the concentrated extract. This result was confirmed by observations of a similar type on patient L D. In another case (C B) the dilute extract D derived from 5 Gm of liver was given first, resulting in a significant reticulocyte response (104 per cent). When the concentrated extract B, derived from the same amount of original liver, was then given, no second reticulocyte response occurred. The results of the observations on patients E S and C B are shown in chart 1.

Concentrated extract C proved

to be more potent than concentrated extract B in another case (E F), as shown in chart 2. The third rise of reticulocytes shown in chart 2 occurred as a result of the daily administration of dilute extract D, derived from the same amount of liver as were the concentrated extracts. Dilute extract D was thus shown to be more potent than concentrated extract C. In another case (R I) concentrated extract B in daily dosage derived from 5 Gm of liver produced a good response of reticulocytes (24 per cent). However, when dilute extract D was given in a daily dosage derived from only 2.5 Gm of liver, a second significant rise to 57 per cent of reticulocytes occurred, as shown in chart 3. This observation suggests that concentrated extract B had suffered a loss of active material during the process of manufacture of more than 50 per cent. Since a repetition of this test on another patient

of liver, was injected daily. This result is shown in chart 5. These observations indicate that the amount of active material in dilute extract D is greater than in concentrated extract E derived from identical amounts of liver. The latter extract, when given subcutaneously, perhaps suffers some loss in effectiveness. In a third case (M N) concentrated extract E, derived from 10 Gm of liver, was injected intramuscularly each day with a resultant rise in reticulocytes to 102 per cent. When dilute extract D, derived from 5 Gm of liver, was then given, a second rise of reticulocytes to 224 per cent occurred, as also shown in chart 5. This would indicate that the amount of active material in dilute extract D is more than twice as great as in concentrated extract E derived from a similar amount of liver.

#### COMMENT

The clinical and economic advantages of parenterally given liver extract in the treatment of pernicious anemia are so numerous and so striking that they outweigh for most patients the slight disadvantage attending the use of a syringe and needle. Some of these advantages may be cited: 1. Use in treating a refractory case when even massive doses (extract from 600 to 900 Gm of liver) are without much effect when given orally. 2. Use in treating the central nervous manifestations of the disease, especially has the outlook

Chart 3—A good response in reticulocytes occurs when the amount of concentrated extract B derived from 5 Gm of liver is given daily. When, however, the amount of dilute extract D derived from only 2.5 Gm is given daily a second definite response in reticulocytes to 57 per cent occurs. This indicates that dilute extract D may possibly have more than twice the potency of concentrated extract B and that the latter has suffered a marked loss of active principle during concentration.

(E F 2) gave no detectable second reticulocyte response, further observations are indicated before this can be stated with certainty.

Concentrated extract E was assayed in three cases. In one case (A L) no response whatever occurred when the material derived from 5 Gm of liver was daily injected subcutaneously according to recommendation. A reticulocyte response, however, followed the immediately subsequent daily administration of dilute extract D derived from 5 Gm of liver given intramuscularly. In a third ten-day period concentrated extract E was injected intramuscularly in the same dosage without a further response, as shown in chart 4. In a second case (M K) the daily intramuscular injection of concentrated extract E, derived from 10 Gm of liver produced a reticulocyte peak of 62 per cent. This was, however, followed by a second peak of 119 per cent when dilute extract D derived from 10 Gm

Chart 4—No rise in reticulocytes occurs when the amount of concentrated extract E derived from 5 Gm of liver is given daily subcutaneously. When however a dilute extract D is given intramuscularly in identical dosage a definite response occurs indicating (a) the ineffectiveness of subcutaneously given concentrated extract in suboptimal dosage and (b) the greater potency of dilute extract D.

Chart 5—Patient M K. A slight rise in reticulocytes occurs when the amount of concentrated extract E derived from 10 Gm of liver is given daily intramuscularly. When dilute extract D is given in identical dosage a second even greater response occurs indicating a greater potency of the dilute extract. Patient M N. A rise in reticulocytes occurs when the amount of concentrated extract E derived from 10 Gm of liver is given daily intramuscularly. When dilute extract D is given in one half this dosage (derived from 5 Gm of liver) a second even greater response occurs indicating that dilute extract D has more than twice the potency of concentrated extract E.

for patients with ataxia been made immeasurably brighter since the introduction of extract for parenteral use. 3. Use in treating a patient with a severe infectious state such as sepsis or pneumonia, or when swallowing is disturbed, as after dental extraction or tonsillectomy. 4. Use during conditions associated with impaired functioning of the gastro-intestinal tract.

—nausea, vomiting, diarrhea — or even with simple anorexia, especially when an aversion to oral liver occurs. Unfortunately, these advantages have as yet not been fully utilized, owing in part to the obscurity surrounding the specifications of the available parenteral products and in part to the relative novelty of the method. The emphasis placed on "purification" and "concentration" has undoubtedly obscured the obvious fact that in the long run the simplest process in which the greatest amount of the original activity of the liver is conserved will be the most economical to the consumer.

The preparation of effective extracts of liver for parenteral use from the fraction G of Colin is relatively simple and is already being carried out by several large hospitals. Desiccated commercial preparations of fraction G weigh about 4.2 per cent of the original bulk of the fresh liver and have already lost about 35 per cent of the original potency. This powdered extract may be dissolved in hot water, neutralized with sodium hydroxide, and allowed to settle for a week in the ice-box after a preservative has been added. The supernatant fluid when passed through a Berkefeld filter results in a solution suitable for parenteral administration. The "concentration" of commercial preparations may be emulated if desired by dissolving as much of the original 4.2 Gm. of powder as will stay in solution in from 3 to 20 cc. of water.

If an attempt is made to dissolve 4.2 Gm. of fraction G in each of such volumes of water as will result in final volumes of liquid of 20, 15, 10 and 5 cc., respectively, increasing amounts of precipitate appear on sedimentation as the volumes decrease. Under these circumstances, the volumes of centrifugated sediments are about 2.5, 3.5, 7.5 and 90 per cent, respectively, of the foregoing final volumes. A picture of the inherent difficulties of concentration is afforded by this simple experiment. The evidence presented, which indicates losses of potent material with concentration, suggests that these visible residues are not altogether composed of inert material.

Solutions of the material derived from 100 Gm. of liver in 20 cc. of water should be of such potency that the extract derived from 10 Gm. of liver given daily or from 100 Gm. of liver given weekly is ordinarily sufficient to produce a maximal response of reticulocytes and red blood cells and to keep the patient in constant remission. A certain amount of the active material in more concentrated preparations will be lost. These apparently simple procedures result, curiously enough, in a tenfold increase in cost in certain of the available commercial products, not to mention an actual loss of active principle, which is often considerable. We fail to perceive, therefore, the advantage of further refinements, which may add to the cost of the process and conceivably diminish the quantity of active principle. As seen from our data, the dilute extract used was always more potent and in two instances was probably more than twice as potent, as concentrated extracts derived from identical amounts of liver.

It should be noted that this does not mean that concentrated products of identical volume, but derived from greater amounts of liver, may not contain more active material, as shown in case C. B. Indeed, it cannot be denied that, by dissolving a large amount of the powdered extract in a small quantity of water, a definite advantage is gained. Let us assume that a concentrated extract in which is dissolved material derived from 100 Gm. of liver in 3 cc. of liquid contains only about

50 per cent as much of the active principle as a dilute extract that is derived from the same amount of liver, although dissolved in 20 cc. of liquid. It then follows that the 3 cc. of "concentrated" liver extract will be equivalent in potency to 10 cc. of "dilute" extract.

The objectionable features of the present situation are simply that no quantitative statement of these differences in potency is available, and that each extract is stated to contain all the potency of the original liver. It is self-evident that the simplest process that conserves the greatest amount of the original active principle of the liver will in the long run produce the most economical product. If concentration means the loss of considerable amounts of the active principle of the original liver, the consumer will naturally have to pay more for the remaining amount of active material. The specifications of a liver extract should not be based, as at present, on the amount of active principle with which the manufacturer began to work but on how much remains in the finished product. A discussion of the bearing of similar inadequacies on the economics of the oral therapy of anemia will be presented elsewhere.<sup>18</sup>

#### SUMMARY

The commercial extracts of liver for parenteral use are prepared in various concentrations, and descriptions of their potency are often vague. It was considered desirable to attempt comparative assays of the different products, using the principle of the "double" reticulocyte response on the same patient. This method necessitates the use of uniform suboptimal doses of liver extract given daily in successive ten to fourteen day periods.

Use of this method demonstrates that certain "concentrated" and "refined" solutions of liver extract for parenteral use have suffered a marked loss in the active principle, amounting possibly in certain cases to more than 50 per cent of the potency of the fraction G of Colin, commonly used as the starting point in these preparations.

Until the specifications of the various commercial extracts for parenteral use are clearly defined in terms of what is a just maximal dose, it will be impossible for the practicing physician to obtain an accurate impression regarding the relative potency of the various extracts.

371 Commonwealth Avenue—Boston City Hospital

#### ABSTRACT OF DISCUSSION

ON PAPERS OF DRs. BETHELL, GOLDBAMEP, ISAACS AND STURGIS AND DRs. DAMESHEK AND CASTLE

DR. L. G. ZERFAS, Indianapolis. I wish to bring out two points: first, the importance of the diet in the treatment of idiopathic hypochromic anemia, in addition to the iron, and, second, the desirability of correcting any pathologic condition that may be causing a loss of blood. Regarding the paper of Drs. Dameshek and Castle, certainly whole raw liver is the basis of all the liver extract fractions. Unfortunately it is difficult to administer, and various fractions derived from a given amount of liver indicate that not all of the active principle is obtained. Minot has estimated the loss to be from 30 to 35 per cent. There are other experiments which bear out what Drs. Dameshek and Castle have said. Dr. Ryman has taken 10 Gm. of raw liver and digested it with gastric juice with that amount of liver he was able to produce a maximum reticulocyte response in pernicious anemia. My associates and I have taken one vial of liver extract, the amount derived

<sup>18</sup> Castle, W. B. and Dameshek, William. Research for the Benefit of the Consumer of Commercial Remedies for Anemia. *Tr. A. Am. Phys.* 1934 to be published.

from 100 Gm of liver, incubated it with normal human gastric juice, from 50 to 100 cc, and obtained maximal reticulocyte responses. This probably means that there are other substances in the liver extract on which the intrinsic factor of the gastric juice acts to produce an additional amount of active principle. The fact that 10 Gm of raw liver incubated with human gastric juice or one vial of liver extract so treated can produce a blood response equal to that produced when from 200 to 300 Gm of whole liver is fed daily indicates that there is another substance in the extract aside from the active principle, which is lost through fractionation. It is only reasonable to assume that there must be some loss of active principle by chemical fractionation. Drs Dameshek and Castle brought out that there is a great variation in the potency of different commercial preparations largely because their potency has been based on the amount of original liver from which the fractions were derived rather than on a definitely standardized means of testing. Some such methods as they utilized should be employed. When the diagnosis of pernicious anemia is made and liver extract or stomach tissue or other potent substance is recommended, the patient may simply go to the drug store and buy the material, in which instance he regulates his own treatment. When the patient receives injectable liver extract, the physician has an opportunity to regulate the therapy and to observe the clinical condition of the patient, all of which is vitally important to the patient's welfare.

DR CYRUS C STURGIS, Ann Arbor, Mich. I wish to emphasize two points. If one wishes to obtain an effect from iron in the treatment of any anemia, there are two things one must consider. The first is that iron will do no good unless there is an iron lack or deficiency in the patient. Secondly, an effect on the anemia will not be produced by the use of iron medication unless very large doses of this drug are given. The dose in the Pharmacopeia is very much too small. For instance the dose of reduced iron is 1 grain (0.065 Gm). I give 0.5 Gm three times a day, or  $22\frac{1}{2}$  grains (15 Gm) of iron daily in order to produce an effect. Drs Dameshek and Castle may be criticized by some because they have placed a great deal of dependence on the reticulocyte response as a criterion of the efficacy of the preparations which they have injected. However, I believe they are entirely correct. It is true that one criterion of the effectiveness of a drug in pernicious anemia is the amount of hemoglobin and red blood cells produced in a given period of time. After six or seven years' experience with the reticulocyte response I am convinced that it is likewise a very accurate method of assay of any preparation employed in the treatment of pernicious anemia. Various criticisms have been offered in rejecting the reticulocyte response as a method of assay, but I think that experience over these years indicates that it gives valuable and correct information. Some say that the methods of staining reticulocytes are ineffective, others that too much dependence is placed on the peak of the reticulocytes to tell whether the drug is effective or not, but despite these criticisms I believe that the value of this method has been demonstrated.

DR W P MURPHY, Boston. There are three means of testing the potency of a liver substance for use in pernicious anemia: (1) the rate and magnitude of the reticulocyte rise, (2) the rate of the erythrocyte increase and (3) the determination of the amount of material necessary to maintain the blood at a normal level in patients observed over long intervals of time. Owing to individual variations perhaps because of complicating factors or even seasonal variations, data concerning the actual potency of material are of value only if obtained in a large series of cases uniformly treated and, in the case of maintenance treatment only if followed for relatively long periods. Observations of the magnitude of the reticulocyte rise are not a reliable means of testing the potency of actively potent material. Although the method used by Drs Dameshek and Castle may eliminate some of the difficulties observed in the use of this method if used in a large series of cases, there are obvious reasons why it may not be reliable. The two latter methods offer an accurate and reliable means of determining the potency of and recording the actual value to the patient of any liver substance used. Last year I presented data showing the rate of increase of the erythrocytes following the use of a concentrated solution of liver. In a consecutive

series of more than forty cases showing initial red blood cell counts below the 2,000,000 level, the average daily increase was 100,000 cells during a period of one month. The amount of material used ranged from four to seven vials of 3 cc each prepared from 100 Gm of liver (Lederle). In the 1934 Scientific Exhibit a series of ninety cases is presented followed for periods varying from one-half to two and one-half years, in which the blood level was maintained at 5,000,000 or more cells per cubic millimeter, the average interval between injections of one vial, or 3 cc, of the concentrated solution was a little over one month. It may be seen from these data that the patients are being treated and maintained in excellent condition with a minimal dose of material and with the least disturbance to the individual. This is of particular interest because many patients come from long distances and more frequent dosage would be a considerable expense and inconvenience to them. Considering the small cost of the material and the fact that few injections are necessary, it is obvious that these patients are being maintained at a minimum of expense and inconvenience to them. I believe that these methods should be used not only to determine the purely academic question as to the relative potency of various concentrations of liver extract but the more important one, both to the patient and to the physician, of the most efficient and most satisfactory extract to use for the patient.

DR ADOLPH SACHS, Omaha. In the various forms of iron deficiencies whenever iron decreases the whole blood copper increases. As the anemia improves, the iron increases and the whole blood copper decreases. This offers another guide by which one can follow the benefit of any therapeutic measure. In 250 determinations made on normals, it was found that 132 micrograms of copper per hundred cubic centimeters of blood is the normal whole blood copper. This is similar in the female and in the male, with a very small variance. There are but few exceptions. In over 250 determinations a copper anemia has never been found. So in therapy I always find that copper is already present in sufficient quantity to supply the amount needed. I find in my experiments that copper is probably a great biologic catalyst.

DR C W EDMUNDS, Ann Arbor, Mich. The view in regard to the difference in potency in the different preparations derived from the same amounts of liver is, of course, of comparatively recent origin. The members of the Council on Pharmacy and Chemistry realize that the descriptions of potency in N N R at present are not strictly correct. A very serious problem has to do with the description and testing of these products under the new Pharmacopeia. It is most difficult to decide on some phrase that will describe the potency of these products. A product from 100 Gm of liver when it is in 10 cc may be of an entirely different potency from a product derived from 100 Gm when it is concentrated to 3 cc. In all the comments that have been made, I haven't heard one suggestion as to how this could be expressed in the Pharmacopeia, and that is of the utmost importance from the standpoint of the government supervision of these products. The chapters for these new monographs have all been prepared with the help of Drs Minot, Castle, Sturgis and Isaacs and are as perfect monographs as can be obtained in the present state of knowledge, except for this final phrase concerning the statement of potency. The assay is on reticulocytes, which is the only available and practical test at the present time. The statement giving the amount of liver used is not sufficient, except from the economic standpoint it is the amount of performance and potency that is important. I have suggested to Dr Isaacs and to Dr Minot that products should be labeled to show how many cubic centimeters or grams of the product would bring about the standard increase in reticulocytes. In other words, the reticulocyte increase with a certain number of red cells is the important thing. The matter is not settled. The copy is at the present moment in Dr Minot's hands and, I think, will go before the general committee of revision within the next two weeks and I hope we can come to some satisfactory solution of this really extremely difficult problem.

DR FRANK H BETHELL, Ann Arbor, Mich. Most of our patients, before coming under observation, had had a reasonably adequate and well balanced diet. However an occasional

individual has been seen, with achlorhydria and without a history of any blood loss, who has presented an anemia of secondary type. Such patients are usually elderly, and the diet may have been inadequate over a period of many years. It is in this group that we feel dietary correction to be of particular importance. In the treatment of patients with iron deficiency anemia we do not believe that any diet is of specific benefit. In regard to copper, we have shown experimentally following the work of Hart, Steenbock, Elvehjem and Waddell that copper apparently plays an essential role in the utilization of iron in hemoglobin formation. However, any ordinary diet will supply between 2 and 4 mg of copper a day, which is as much as is supplied by the recommended dosages of many therapeutic preparations of iron and copper.

Dr WILLIAM DAMESHA, Boston. Dr Murphy's criticisms undoubtedly are correct in many respects. The reticulocyte response at times does not work, particularly in refractory patients. On the other hand, as Dr Murphy has brought out in one of his articles on the subject, the reticulocyte rise and not the red cell response is important when the liver extract is given not in maximal but in submaximal dosage. Regarding Dr Murphy's criticism of the number of cases, I wish to state that we have utilized this method of investigation in fourteen cases, in ten of which satisfactory observations were made. In each case comparisons of two or more extracts were made. This has been done over a period of a year and a quarter. We do not regard the job as finished and hope to interest others. It has been very difficult to obtain suitable patients. Many patients obtain all kinds of "shotgun" medications containing a certain amount of liver extract, and when they come to the hospital for treatment they are not suitable for testing. Dr Castle and I have felt therefore that it was necessary to test the materials out on the same patient. Individual patients may differ greatly in their manner of response. In the same patient, if the material is given in the same fashion daily the "double" responses are of great significance. These observations may possibly be considered of only academic interest since all the extracts tested work more or less well. We as physicians should, however, know as much as possible about any pharmaceutical product that we administer, especially as our patients have to pay for our services and prescriptions. Dr Edmunds has brought out some very important points. Dr Castle and I have many times discussed the question of how these products should be labeled. We have found that an easily prepared dilute liver extract almost always produces a maximal response from the daily injection of the material derived from 10 Gm of liver. Our interest in the matter is not to advocate any particular type of commercial product but to urge the definition of the potency of all acceptable products in terms of that dosage of each which will have approximately the same hematopoietic effect. Such a definition should meet no objection on the part of any reputable commercial drug firm.

**The Phylogeny of Blood-Forming Tissues.**—In phylogeny the fundamental blood-forming organ, the spleen, apporions its functions of lymphocytopoiesis and erythrocytopoiesis at the higher levels, respectively, among lymph nodes and bone marrow. It retains prominently in the mammalian adult only the functions of lymphocyte and monocyte formation. Since the lymph nodes also perform these functions to a high degree, the spleen represents as regards its primary function of blood formation only a vestigial organ. However, by virtue of its reticular stroma, its lymphocyte parenchyma and its sinusoidal venous circulation, it retains its evolutionary and fetal potentiality for the formation of the red cells. In this case of adenocarcinoma of the prostate both the lymph nodes and the bone marrow were largely eliminated from the hemocytopoietic system by reason of extensive metastases, and the spleen was stimulated to assume as a compensatory measure its original erythrocytopoietic activity. The condition roughly parallels the evolutionary level of the Amphibia in which the bone marrow has only slight erythropoietic activity, the spleen being the dominant organ in the production of red cells.—Jordan, H. E. Extramedullary Erythrocytopoiesis in Man. *Arch. Path.* 18:1 (July) 1934.

## THE EARLY HISTOLOGIC DIAGNOSIS OF CARCINOMA OF THE UTERINE CERVIX

HENRY SCHMITZ, M.D.

AND

E. L. BENJAMIN, M.D.  
CHICAGO

In a previous paper the histologic changes in seventy-five cases of chronic cervicitis as revealed by serial sectioning were described.<sup>1</sup> In six of these, blastomatoid changes consisting of cellular and nuclear deviations in size, shape and chromatism, epithelial heterotopia and stroma reaction were present. We designated these changes as neoplasia. It was made clear that it was imperative to follow up the patients in whom this neoplasia was found, to determine the significance of the cellular changes. To these six cases, in the course of time, three more were added, so that we have now nine cervixes with blastomatoid changes. Eight were treated immediately with adequate doses of radiation as used in carcinomas, and normal anatomic conditions were obtained. One patient was not treated and a report of the case will now be given.

Jan 30, 1933, a low circular amputation of the cervix of Mrs. S. was done. The clinical diagnosis was leukoplakia of the cervix, and the amputation was done because the pathologic changes were extensive. The patient had lost 30 pounds (13.6 Kg.) during the last year. She had had a profuse brownish discharge mixed with blood for four or five months three years previously, and the discharge had been present continuously since May 1932. There was no odor, but the underwear was saturated daily. A cystic tumor of the ovary had been removed fifteen years previously and laparotomies for two tubal pregnancies had been performed twelve and thirteen years previously. The menstrual history was not important except that the menopause had occurred two years previously, when the patient was 44 years of age.

Pathologic examination showed that sections extending in the long axis of the cervical canal to include 10 mm of the vaginal lip of the cervix were covered with stratified squamous epithelium, and another 11 mm lined with columnar epithelium was partially eroded (fig. 1). The mucosa of the vaginal lip was thicker than normal, in spite of desquamation (artifact) of part of the superficial zone. There was a well developed stratum granulosum present, consisting of from three to four layers of flattened cells containing keratohyaline granules and interposed between a superficial clear eosinophilic cellular layer and a rete malpighii. The palisade arrangement of the basal layer was fairly constant, the basement membrane was intact. The tunica propria was edematous and infiltrated with lymphoid cells, plasma cells and polyblasts. Numerous pre-formed vessels, lined with a single layer of endothelium, were plainly seen (fig. 2).

As the stratified squamous epithelium approached the external os it increased in thickness to form broad flat epithelial papillae. The stratum granulosum became more distinct. The reaction within the tunica propria was exaggerated. An abrupt transition of the stratified squamous epithelium was seen exhibiting neoplastic tendencies characterized by loss of normal architecture, with a thickened stratum corneum, well developed stratum granulosum and hypertrophy of the rete malpighii. Loss of polarity, hyperchromatism and variations in size and shape were exhibited within the rete malpighii (fig. 3). The average diameter of 500 nuclei in this area was 0.020 mm, the extremes were 0.012 mm and 0.036 mm. The average diameter

Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 15, 1934.

1. Schmitz, Henry, McJunkin, F. A. and Macaluso, M. A. Histopathology of Epithelial Hyperplasia and Neoplasia of the Cervix Uteri. *Am. J. Obst. & Gynec.* 27:336 (March) 1934.

of 500 nuclei in the rete malpighii of the mucosa of the vaginal lip was 0.017 mm, the extremes were 0.012 and 0.024 mm. An intense stroma reaction was present beneath the epithelium. The diagnosis was leukoplakia with early epidermoid carcinoma of the uterine cervix.

The cervix healed by first intention. The patient returned, June 26, complaining of a recurrence of the brownish discharge since June 5. However, on examination nothing of importance was found until October 26, when friable tissue was discovered at the external cervical os. A biopsy specimen was taken and the diagnosis of epidermoid carcinoma of the cervix (fig 4).

Fig 1—Leukoplakia, beginning epidermoid carcinoma of the uterine cervix. Transition in the character of the mucosa, downward growth and broadening of the epithelial papillae and subepithelial chronic inflammatory infiltration are shown. The lighter area to the right in the stratum mucosum is due to a technical staining defect. Reduced from a photomicrograph with a magnification of 65 diameters.

was made. The patient was treated with 50 mg of radium element placed directly in the cervical canal until 2400 milligram element hours was attained, and with the application of roentgen rays of 800 kilovolts to a suprapubic and a sacral field. The dosage applied to each field was 2,100 roentgens in ten fractional doses. Since the anteroposterior diameter was 16 cm, a dose of 2,600 roentgens was attained in the midpelvis. The patient had a rather severe reaction but overcame it gradually within two months, at which time examination revealed an anatomic healing of the cervix.

This is an instance in which ten months prior to a diagnosis of typical carcinoma, the microscopic examination of the cervix showed leukoplakia, atypia and neoplasia of the epithelial cells, a negligible amount of epithelial heterotopia and a stroma reaction. Such blastomatoid changes are apparently irreversible and should be considered as the earliest histologic evidence of carcinoma of the uterine cervix. This case is reported as proof that such blastomatoid changes should be considered malignant. We are of the opinion that, if such cases are not treated adequately at the time of their detection, they should be kept under close clinical observation. If marked heterotopia and breaking through of the basement membrane have occurred, the patient should be immediately and adequately treated by surgery or radiation. It will become the duty of the physician and pathologist to subject all cervical tissues removed at operation to serial sectioning and the changes of neoplasia should be considered as the earliest histologic evidence of carcinoma of the uterine cervix.

The detection of early carcinomas of the cervix can be attained only by employing palpation and inspection of the genital organs as part of every physical examination. Linear cauterization of the vaginal portion of the cervix will cure chronic cervicitis. If the lesion does not heal or if it recurs, low circular amputation of the diseased part of the portio vaginalis and microscopic examination of serial sections of all the tissues will lead to an early diagnosis of cancer.

## ABSTRACT OF DISCUSSION

DR EMIL NOVAK, Baltimore. In the great majority of cases, the diagnosis of cervical cancer can be made with reasonable certainty by the simple clinical methods of inspection and palpation, the microscope being used for confirmation. In the early and doubtful cases, the microscope must make the diagnosis. Since it is this early group which physicians are constantly striving to increase, the microscopic examination is becoming increasingly important but increasingly difficult. The reason for this lies in the fact that physicians are learning to recognize that certain epithelial cell characteristics which they had formerly looked on as distinctive of cancer may be found in lesions that are obviously not malignant. In the case of frank carcinoma, the microscopic diagnosis can usually be made almost at a glance, and with the low power, from the characteristic disorderly and invasive pattern of the growth. When the latter is lacking, it has been rather generally accepted that the presence of such features as mitoses, hyperchromatosis and disparity in cells and nuclei constitutes adequate evidence of a malignant condition. Many errors have been made because of this view, and, in the diagnosis of early epidermoid cervical cancer, evidence of invasiveness must usually be required to establish the diagnosis. During the past few years, the interest of gynecologic pathologists in this new field of "precancerous," "pseudomalignant" and "carcinoid" lesions has been intensified, probably chiefly because of the publications of Hinselmann and Schiller. Even in mild inflammatory lesions, mitoses in the basal layers may occasionally be found, and they are not uncommon in leukoplakia, though the latter is certainly a benign lesion, and though, in spite of a few reported cases, there has been no adequate evidence to indicate that it is a precursor of cancer. The so-called squamous metaplasia is clearly benign, and here again there is little reason to look on it as having any more influence in the development of cancer than pertains to any chronic irritative lesion. Of much greater interest, however, are the cases of what may be called intra-epithelial epithelioma, in which the epithelial layer shows unmistakable evidence of growth acceleration, with large, heavily stained nuclei, numerous mitoses, often parakeratosis, disparity in size of cells and nuclei—in short, all the histologic characteristics of carcinoma except for heterotopia. These pictures, so similar

in many instances to the Bowen's disease of dermatologists that this term has come to be employed for lack of a better one, are being encountered more and more often. Do they represent early cancer or not? There is no way to determine this except to learn their effect on the life and health of the patients.

DR JOSEPH COLT BLOODGOOD, Baltimore. It was my privilege to hear Dr Schmitz with my classmate Dr John Clark and Dr Burnam give the first symposium on the treatment of cancer of the cervix with radium, in Chicago in 1914 or 1915. Each had a somewhat different method of treatment, but they all used radium salts or radon, and apparently at the end of five years their results were identical. They were curing

a certain percentage even of inoperable cases, and today their treatment is accepted throughout the world as the treatment for cancer of the cervix. Dr Schmitz is discussing early histologic diagnosis of cancer of the cervix, and my opinion is that, when one must use the microscope to demonstrate whether the lesion of the cervix is malignant or not, the chances of a cure are best. The fact that Dr Schmitz devotes his entire paper to this most important side is a demonstration that he is getting early cases. The cures today in the great clinics of the world are about 35 per cent, all cases being grouped together, and they vary from more than 90 per cent in the early stage to less than 10 per cent in group 4, the group of inoperable and extensive cancer. Nevertheless in the majority of cases cancer of the cervix is a preventable disease, and this prevention rests on the education of mothers and the education of physicians who take care of mothers' special troubles. Every woman should have a pelvic examination within six months and one year after the birth of her first child, and at frequent intervals thereafter as her physician thinks best. This is as important as the protection of a child at 6 months of age against diphtheria by the use of toxoid. The early histologic diagnosis of cancer of the uterine cervix is the next most important thing. Ultimately, in the majority of cases, cancer of the cervix should be found with the microscope, and when it is found in this early stage the chances of a cure by physicians properly trained in the use of radium should be more than 90 per cent.

DR FRED WETHERELL, Syracuse, N. Y. Dr Schmitz finds early cases in his own private practice, but the cases that I see are the late cases which have been seen by the family physician. It is sad to see years go by and the cases referred to one in advanced stages, cases which have gone for months and sometimes even years. When the time comes that

Fig 3—Leukoplakia of the nonkeratinizing epithelium of the portio vaginalis at the lip of the uterine cervix. Hyperkeratosis, parakeratosis and the formation of a well defined stratum granulosum are shown. Intercellular, intranuclear and perinuclear edema with variations in size and shape of the cells and hyperchromatism are present in the stratum spinosum and stratum germinativum. this group and other individuals interested in early diagnosis can have the patients which will make Dr Bloodgood's and Dr Schmitz's workers question the biopsy sections the answer will have been reached as Dr Bloodgood has suggested to early cure and cure in a large percentage of cases.

DR HENRY SCHMITZ, Chicago. The points I wanted to bring home are as follows. If neoplasia is found in the cervix

after surgical amputation and there is no penetration of basement membrane, it may be assumed that the surgical amputation has removed all the pathologic tissue, and follow up of these cases is all that is really necessary. On the other hand, if in these early carcinomas the penetration of basement membrane has occurred so that the classic microscopic diagnosis of carcinoma can be made, it is clear that these cases should be

treated adequately according to established principles. I am positive in making the statement that if cases could be treated at this time and not when they are clinically recognizable, more than 90 per cent of the cases of carcinoma of the uterus would obtain a good five year end result.

## THE ESTIMATION OF FUNCTIONAL DISABILITY IN THE PULMO- NARY FIBROSES

WILLIAM S. McCANN, M.D.  
ALBERTO HURTADO, M.D.  
NOLAN KALTREIDER, M.D.  
AND  
WALTER W. FRAY, M.D.  
ROCHESTER, N. Y.

Pneumonocosis presents a medicolegal problem of major importance. Many studies exist which deal with its etiology and pathogenesis and its diagnosis by roentgenograms, but so far little attention has been paid to its physiologic aspects, though their practical importance is obvious. Especially is this so in view of the growing tendency to adjust awards of workmen's compensation to the degree of disability. In order to do this properly it is essential that objective means of estimating disability be sought which will be fair alike to workman and employer. With this in mind we have carried out investigations on the respiratory function of fifty-three cases of pulmonary fibrosis of various types not all of which were pneumonocosises.

The function of respiration is one jointly mediated by the heart, the blood and the lungs. It was apparent at the outset that the functional examination should be

From the Department of Medicine, University of Rochester School of Medicine and Dentistry, and the Medical Clinic of the Stroug Memorial and Rochester Municipal hospitals.

Read before the Section on Preventive and Industrial Medicine and Public Health at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 14, 1934.

complete as regards all three of these factors. Our studies of the lungs have dealt with the pulmonary capacity and its subdivisions, with the tidal air, dead space, alveolar gases and response of the pulmonary ventilation to exercise. They have included the usual diagnostic roentgenographic studies together with measurements of areas of the pulmonary fields during maximum inspiration and expiration, with observations as to the behavior of the ribs and diaphragm. The blood has been carefully studied in each case as to count, hemoglobin, cell and plasma volume and gas content, particularly of the degree of saturation of the arterial blood with oxygen. The heart has been carefully measured roentgenologically. Electrocardiograms have been made in each case, and the cardiac output has been measured in a large proportion of them, Grollman's<sup>1</sup> method being used. The enormous amount of data accumulated cannot be completely presented here. It is in the process of publication elsewhere. We will confine ourselves at this time to a discussion (1) of the correlation of roentgenographic studies with the measurements of the pulmonary capacity and of the saturation of the arterial blood with oxygen, and (2) of our observations on the ventilation of the lung during exercise.

The total pulmonary capacity and its subdivisions were measured by the method of Christie.<sup>2</sup> While similar measurements have been made previously by many investigators, a search of the literature revealed data concerning few normal subjects and no basis on which to estimate the normality of the values observed. Hurtado and his co-workers<sup>3</sup> undertook to establish

between the vital capacity and the radiologic chest volume at maximum inspiration, measured with a planimeter traced on a roentgenogram made by a special technic at a distance of 6 feet. This technic involved the use of filters through which the films were doubly exposed, once at maximum inspiration and once at maximum expiration. A formula has been derived by which the normal value of the pulmonary capacities may be predicted with an agreement between predicted and observed values within 15 per cent.<sup>4</sup>

Pulmonary Capacity and Its Subdivisions in Fifty-Three Cases of Pulmonary Fibrosis

Group		Total Capacity per Cent of Normal	Vital Capacity per Cent of Normal	Residual Air per Cent of Normal	Ratio Residual Total per Cent	Arterial Saturation with O per Cent
I	Average	84	73	125	32	94.0
	Range	65-99	59-87	10-192	20-43	91.4-98.5
II	Average	95	80	135	34	89.5
	Range	75-109	36-76	130-212	37-43	81.5-92.1
III	Average	77	62	212	30	90.0
	Range	50-105	28-86	105-215	26-56	80.6-96.3
IV	Average	79	62	141	38	97.8
	Range	74-89	58-70	97-197	28-49	92.2-95.7
V	Average	82	47	205	54	90.0
	Range	69-97	42-61	135-262	44-69	87.3-92.7
VI	Average	60	43	123	56	83.8
	Range	58-64	32-57	62-176	34-61	71.9-91.9

The normal partition of the pulmonary capacity between vital capacity and residual air has also been determined, and also of the mid capacity (taken at the end of a normal expiration). The relations between these subdivisions as determined in fifty normal males and fifty normal females are shown graphically in figure 1. The grouping of dots about the lines representing mean values gives the normal limits of variation observed.

In order to determine to what extent the roentgenograms of the lungs give clues as to the degree of functional impairment of respiration, the fifty-three cases of pulmonary fibrosis were divided into six groups, according to the anatomic type of fibrosis revealed. No other satisfactory basis of classification could be found. An etiologic classification was impossible for several reasons. In the first place it is never possible to determine with certainty the etiology of pulmonary fibrosis from a roentgenogram, even when a reliable history of occupational exposure to dust is obtained. It is difficult to exclude the possibility of infectious fibroses, particularly in a group composed largely of litigants who cannot be relied on to give the full truth regarding nonoccupational illnesses. Furthermore the majority of our patients were in the fifth and sixth decades, in which cardiovascular disease has a fairly high incidence as a cause of pulmonary fibrosis and respiratory disability.

The grouping of the cases of fibrosis is as follows:

I More than usual fibrosis in patients giving no history of asthma. A typical roentgenogram of this group is shown in figure 2. The group includes incipient cases of pneumoconiosis, chronic nontuberculous respiratory infection and cases presenting cardiovascular disease making a total of twenty-two cases.

II More than usual fibrosis of linear type with emphysema in patients giving a history of asthma. A roentgenogram typical of this group of seven cases is shown in figure 3.

III Simple nodular fibrosis giving the diffuse 'snowstorm' appearance characteristically produced by miliary tuberculosis.

Fig. 1.—Relative values of the various subdivisions of the pulmonary capacity observed in sixty normal males and fifty normal females. The dots represent individual observations grouped about the mean values.

normal values by a study of sixty normal men and fifty normal women. The values of pulmonary capacity were correlated with various bodily and roentgenographic measurements. The best correlation was found to exist

4 Hurtado and Fray,<sup>3</sup> Hurtado, Fray, Kaltreider and Brooks.<sup>3</sup>

or silicosis. Figure 4 is typical of this group, which includes fifteen cases.

IV Similar to group III except that agglomeration of nodules is beginning, with emphysema in intervening areas. Figure 5 is typical of the group of three cases.

V More advanced agglomeration forming dense shadows in the midzone and upper portions of the lungs with marked emphysema of the bases, tenting of the diaphragms, and the like. Figure 6 is typical of the three cases of this group.

VI Fine, diffuse reticular fibrosis without nodulation. Figure 7 is typical of three cases of this group.

In figure 8 are graphically shown the average values for the predicted and observed values of pulmonary capacity for each group. In this, one observes a progressive tendency for the vital capacity and total capacity to diminish as the degree of fibrosis increases, except in group II, in which the total capacity is nearly normal, owing to the large value of the residual air, probably representing the emphysema induced by the repeated attacks of asthma.

The functional significance of these conditions is better appreciated by the data in the accompanying

in every case in which the ratio of residual air to total capacity is more than 49 per cent. With the ratio at 45 per cent only one patient and at 40 per cent only four patients were normally saturated with oxygen.

One might be tempted to assume that the borderline of complete disability had been reached whenever the saturation of the arterial blood at rest was less than normal. This would undoubtedly be a faulty assumption in view of the fact that Hurtado<sup>5</sup> found that the arterial blood of natives of the high Peruvian Andes is always less saturated with oxygen than is the case with normal individuals at sea level. In spite of the partial anoxemia, the Peruvian natives are capable of performing hard labor in the mines.

In the hope of finding some basis for estimating the capacity for work of our subjects, we have studied the respiration during physical work. The subjects sat in a chair-like seat from which they operated the pedals of a bicycle, which turned a metal wheel against the resistance of a simple mechanical brake. The

Fig. 2—Typical of group I. The total capacity was 6 per cent and the vital capacity 127 per cent below normal. The residual air was 173 per cent above normal. The ratio RA/TC was 27.5 per cent.

Fig. 3—Typical of group II. The total capacity and vital capacity were decreased to 85 and 41 per cent of normal respectively. The residual air was 241 per cent of normal. The ratio RA/TC was 62.5 per cent. Arterial oxygen saturation was 92 per cent.

Fig. 4—Typical of group III. The total capacity was 71 per cent of normal, vital capacity 58 per cent and residual air 116 per cent. Ratio RA/TC was 36 per cent. Arterial oxygen saturation was 81 per cent.

table, in which are given the average data for pulmonary capacity and its subdivisions, and the range of variation within each group. These data are compared with values for the saturation of the arterial blood with oxygen.

The usual changes observed in these cases of pulmonary fibrosis consisted of a moderate decrease in the total capacity, a more marked decrease in the vital capacity and in most cases a moderate increase in the residual air. Not infrequently the latter volume was found to be abnormally high. It appears from this table that the average values of these changes are proportional to the degree of fibrosis, as revealed in the roentgenogram, but the wide variation within each group indicates that a very imperfect idea of the degree of functional impairment of the lungs can be derived from the roentgenograms alone. The necessity for individual and complete study of each case is obvious.

In the analysis of our data the ratio of residual air to the total pulmonary capacity appears to have great functional significance. The saturation of the arterial blood with oxygen is less than the normal 94 per cent

subjects were urged to exert themselves to the utmost, during which time the expired air was collected in a spirometer. The volume of this air and the rate of respiration was recorded graphically and charted for each half minute period. The actual work performed was not measured, the object being merely to record the maximal ventilation of the lungs to which the subject could attain in any half minute period.

Sturgis, Peabody, Hall and Fremont-Smith<sup>6</sup> observed the maximal minute volume of respiration in twelve young men. Their observations led them to suggest a formula for roughly predicting the maximal minute volume, which they found to be attained when the tidal air equals one third of the vital capacity and the rate of breathing is 34 per minute. The maximum minute volume was about twelve times that of the value observed when the subject was lying down at complete rest. This maximum value was one

that could be maintained for only short periods (one and one-half minutes of extreme effort) They observed that normal subjects were not conscious of breathing at 25 per cent of maximal capacity, and that they were conscious of it at 50 per cent and frankly short of breath when the minute volume was 75 per cent of the maximal value When the vital capacity was reduced artificially by tight binding of the chest the maximal ventilation was likewise reduced, and the percentages at which moderate and severe dyspnea were noted were relatively the same, 50 and 75 per cent, respectively These results, however, were attained with highly intelligent, cooperative, trained subjects who could be depended on to exert themselves to the utmost of their ability

In our series it was possible to select ten subjects with pulmonary fibrosis and five subjects with emphysema who were not engaged in litigation and who appeared to be highly cooperative In these cases the average vital capacity observed was 2.50 liters From the vital capacities the maximum minute

fibrosis, in which the mean value of the former was 66.8 per cent and of the latter 64.6 per cent The lack of a more perfect correlation between these two values probably depends on the fact that individuals with pulmonary fibrosis attain their maximum respiration with a smaller increase in rate than is the case with normal or with emphysematous subjects In this series of twenty-five cases the average rate of respiration was 28, a range of from 20 to 32 per minute If the gross value for ventilation is corrected for dead space and rate of breathing, the effective alveolar ventilation may be obtained We have reason to believe that when correlations are made on effective alveolar ventilation and the vital capacity a closer relationship will be revealed With this in view we are continuing our observations, making improvements in the ergometer used and making determinations of the dead space both at rest and during exercise The dead space is being measured by a new apparatus which permits the taking of eight samples of air from a single expiration, from which the gradient of carbon dioxide or oxygen may

Fig 5—Typical of group IV The total capacity was 75 per cent of normal vital capacity 70 per cent and residual air 97 per cent Ratio RA TC was 28 per cent Arterial oxygen saturation was 93.4 per cent

Fig 6—Typical of group V The total capacity was 69 per cent of normal vital capacity 50 per cent and residual air 138 per cent Ratio RA TC was 44 per cent Arterial oxygen saturation was 87.3 per cent

Fig 7—Typical of group VI The total capacity was 59 per cent vital capacity 39 per cent residual air 130 per cent of normal Ratio RA TC was 48.6 per cent Arterial oxygen saturation was 71.9 per cent

volumes were calculated and the average of these values was found to be 13.79 liters per one-half minute The average of the observed values was found to be 12.33 liters per one-half minute, giving an average agreement within 10 per cent between calculated and observed values These results indicate, therefore, that the Sturgis-Peabody formula gives a roughly correct method of predicting the maximal ventilatory capacity of untrained subjects with pulmonary fibrosis and emphysema

Unfortunately, in dealing with patients who were litigants it was frequently apparent that less than normal effort was exerted However, fifteen of the litigants apparently cooperated well The average maximal ventilation per one-half minute for this group was 17.83 liters for the observed values and 18.85 liters for the values calculated from the vital capacity, an average agreement within 6 per cent, with a range from minus 33 to plus 40 per cent

The correlation coefficient between the percentage of normal vital capacity observed and the percentage of normal maximal ventilation observed was found to be  $0.526 \pm 0.1349$  in twenty-five cases of pulmonary

be determined An ergometer is being employed that will permit accurate measurement of the work done

#### SUMMARY

Fifty-three cases of pulmonary fibrosis due to a variety of etiologic factors were studied from the functional point of view in the hope of arriving at an objective and reliable method of estimating the degree of respiratory disability resulting from fibrosis of the lungs Since the function of respiration is one jointly mediated by the heart, the blood and the lungs, in addition to careful clinical, roentgenographic and electrocardiographic studies, the following observations were made total pulmonary capacity and its partition between vital capacity and residual air, and the mid capacity, the tidal air, dead space, alveolar gases, and the response of the pulmonary ventilation to exercise, clinical and chemical studies of the blood and of its gas content particularly with reference to its saturation with oxygen Since etiologic classification was impossible, the cases were divided into six groups depending on the anatomic type of fibrosis revealed in roentgenograms of the chest

## CONCLUSIONS

1 The comparison of the observed with the normal calculated pulmonary capacity in cases of pulmonary fibrosis indicates that a decrease in the total and vital capacities and an increase in the residual air are characteristic changes in this condition. These changes tend to become more accentuated as the degree of fibrosis increases, but frequent exceptions to this correlation emphasize the fact that one cannot judge accurately the degree of abnormality in pulmonary capacity from roentgenograms alone.

2 The ratio of residual air to total pulmonary capacity is one of great functional significance, the higher the ratio the greater is the tendency to anoxemia. Thus the saturation of the arterial blood with oxygen is less than the normal 94 per cent in every case in which the ratio exceeded 49 per cent, in all but one case in which it exceeded 45 per cent and in all but four cases in which it exceeded 40 per cent.

3 The Sturgis-Peabody formula for predicting maximal ventilatory capacity from the vital capacity is shown to be roughly correct when applied to cases of pulmonary fibrosis. In a group of twenty-five patients with pulmonary fibrosis, comparison of the percentage of normal vital capacity observed with the percentage

Fig 8—Average data of each of the groups I-VI. The left hand column of each pair represents the calculated normal the right hand one the observed values. The total column is the total capacity black representing residual air white the vital capacity. The transverse line represents midcapacity taken at the end of a normal tidal expiration.

of normal maximal ventilatory capacity predicted by the formula gave a correlation coefficient of  $0.526 \pm 0.1349$ , indicating that further work is needed in order to devise a better formula.

4 Patients with pulmonary fibrosis attain maximal ventilation with less acceleration in rate of breathing than in the case of normal subjects or patients with heart disease or emphysema. We are continuing our observations in the belief that a higher correlation between vital and ventilatory capacity will be attained if the effective alveolar ventilation is measured.

## ABSTRACT OF DISCUSSION

DR JAMES L. DUBROW, Des Moines, Iowa. Another approach to the problem of estimating the functional disability in the pulmonary fibroses can be made not only through the roentgen film but also by the clinical examination of the patient. Although it is difficult from the chest film alone to say what form of fibrosis a man has correlation of the clinical with the roentgen observations is of great value. There is a widespread opinion that all forms of pneumoconiosis are due to silicosis, yet if one examines a large number of films of soft coal miners it will be noted that they present undoubted signs of pulmonary fibrosis. While the miners are able to perform their work they suffer from a certain grade of dyspnea, and

their functional and vital capacity is reduced as shown by Brownlee and his associates in England. In cases of pulmonary fibrosis actually due to silicosis, such as those encountered in granite workers and shown on the x-ray film by nodular mottling, the estimation of functional disability is complicated because many of these cases present pulmonary tuberculosis as an associated disease, but, even ruling out pulmonary tuberculosis as a complicating factor, the vital capacity is more seriously reduced. Another form of pneumoconiosis in which the degree of functional disability is even greater in the cases that have come under my observation is asbestosis. The fibrosis shown on the roentgenogram in cases of asbestosis differs from that encountered in silicosis in that it is of a finer type and appears softer and more widespread. Clinically, even without seeing the film, one can make a good guess as to the form of fibrosis by the amount of dyspnea the patient displays, always provided the occupational history has been that of an asbestos worker. An interesting point about asbestosis is that of cardiac changes displayed on physical and electrocardiographic examination. The electrocardiogram shows a right ventricular preponderance, and some of the dyspnea noted is in all probability due to myocardial changes incident to the burden on the pulmonary circulation with the gross load being borne by the right heart. In selected cases of pneumoconiosis reported by me in the *Journal of Radiology* in February I happened to take electrocardiograms in an endeavor to explain the evident dyspnea noted in certain forms of pulmonary fibrosis. The electrocardiographic changes shown in asbestosis seem quite marked.

DR WILLIAM D. McNALLY, Chicago. Did you examine any lungs that had cavities, when you gave your vital capacity data? The test would be no good with the cavities, would it?

DR WILLIAM S. McCANN, Rochester, N. Y. No.

DR McNALLY. In Gutzeit and Groetschels work on the vital capacity and respiratory index in pneumoconiosis, the respiratory index is given as the quotient the vital capacity divided by height of the body in centimeters (20 in normal human beings).

DR BENJAMIN GOLDBERG, Chicago. I have found basal metabolic rates as high as plus 55 in patients having a marked interalveolar fibrosis with no evidence of other disease, such as thyrotoxicosis or leukemia. Apparently an anoxemia occurs in these individuals and the test has been checked several times to make certain of its accuracy. In these instances one must also consider the possibility of an increase in physical effort, associated with the dyspnea produced by the disease, as a factor in increased metabolism.

DR WILLIAM S. McCANN, Rochester, N. Y. With regard to the estimation of the degree of functional impairment from the actual test alone in the first group of patients the average observations of which were rather close to normal, quite a number were workmen between the ages of 40 and 60 who had evidence of myocardial disease (abnormal electrocardiograms). One would expect to encounter arteriosclerotic and hypertensive heart disease frequently in this age group. On the other hand, we had a considerable number of people who had abnormal electrocardiograms who did fairly well with regard to functional capacity, and it all depended, I suppose, on the amount of cardiac reserve they had left in spite of electrocardiographic abnormalities. The high incidence of cardiovascular disease in this age group makes it a bit unfair to compare such a group with normal men of a more youthful type as we have done. We hope soon to have normal standards for men between the ages of 40 and 60 selected for apparent health and from nondusty occupations. None of these patients had cavities that we could demonstrate by x-rays. There may be small cavities in some of them but they were not obvious. We were not dealing very much with the tuberculous group of pneumoconioses. We have not done anything with the formula of which Dr McNally spoke. I was not even aware of it. In regard to basal metabolism, there is one thing which I think should be borne in mind. Some of our patients had an arterial oxygen saturation as low as 70 per cent. If the basal metabolism is determined with a closed system using a rich oxygen mixture the absorption of oxygen there does not necessarily mean the use of that oxygen in

metabolism. It means in many cases building up the oxygen saturation of the arterial blood during the period of the test. It is impossible to get a true determination of the basal metabolism of a cardiac patient who is severely anoxic, or of one with pulmonary fibrosis who is severely anoxic, by the use of a closed apparatus such as the Benedict. On the other hand if the metabolism is determined by means of a Tissot spirometer that factor does not enter in. The oxygen absorption is necessarily determined in the Christie method of determining the residual air. We did not calculate the metabolism from the oxygen absorbed because we believed that a part of it was used in building up the oxygen saturation of the blood.

DR E. R. HAYHURST, Columbus, Ohio: Did you make any breath holding tests?

DR McCANN: No.

## CONGENITAL CYSTIC DISEASE OF THE LUNGS

### A CLINICAL STUDY

HARRY G. WOOD, M.D.

ROCHESTER, MINN.

In a review of the literature, I am unable to find a report of any case of congenital cystic disease of the lungs diagnosed clinically before 1925. In that year, Koontz<sup>1</sup> reported a case and was able to collect 108 other cases. These were all from the European literature and all were based on material obtained at necropsy. This article is to a large extent responsible for the increased interest in, and increased clinical knowledge of the condition existing today. Since the time this paper was published, I have been able, from the American and English literature, to collect twenty-three reports of cases exclusive of those reported in this series. I presume there are more. Of the twenty-three cases a clinical diagnosis was made in sixteen and a diagnosis based on material obtained at necropsy in seven. In one case, the clinical diagnosis was confirmed at necropsy.

Some authors have attempted a classification based on the histopathologic observations. In a general way, all cases fall into two groups: (1) those in which there are single or multiple large cysts containing air or fluid, and (2) diffuse degeneration resulting in the so-called honeycomb type of lung.

The congenital origin of this disease is still a matter of contention, but in many cases the lesions are palpably present at birth and, more important still, in specimens obtained in later life, pigment is absent almost invariably. These facts seem satisfactorily to settle this question.

Theories advanced to explain the condition have been many. Koontz concluded, however, that conjectures as to the cause only beclouded the issue, and that no simple mechanical explanation is available for what is manifestly a developmental anomaly of which many of the factors are unknown.

### MATERIAL

This paper is based on sixteen cases observed at the Mayo Clinic. They have been divided into three groups. Group 1 is composed of six cases in which the diagnosis

appears to be incontrovertible. Group 2 is composed of six cases in which the diagnosis is based entirely on the roentgenologic observations. I believe that a majority of all cases of congenital cystic degeneration can be satisfactorily diagnosed from such observations. Group 3 is composed of four cases that are atypical. In these the diagnosis may be disputed, but careful consideration of the histories and clinical and roentgenologic changes leads us at the clinic to the belief that they are also true examples of congenital cystic degeneration of the lung. This group is included to show that there is a certain group of cases that cannot be diagnosed with certainty.

### REPORT OF CASES IN GROUP 1

CASE 1—A man, aged 36, was examined at the clinic, March 15, 1932. Tuberculosis had not occurred in the family, and the family history otherwise was unimportant. The patient had had influenza in 1918 but had been healthy otherwise until the illness of which he complained. This illness had begun insidiously two years before his examination, without acute infection. Dyspnea gradually had increased and there was occasional palpitation that was worse on exertion. The man had been unable to work for six months previous to his examination. He had not lost weight and he had not had fever. His appetite and digestion were good. There was some cough for one year. When lying on his left side he raised blood-tinged sputum, and dyspnea was increased. A previous diagnosis had been spontaneous pneumothorax. Repeated aspirations (from fifteen to eighteen times) of air did not relieve the condition.

Examination disclosed emphysema on the left side. The temperature was 99.6 F., the pulse rate 93 beats per minute, the blood pressure 118 mm. of mercury systolic and 86 diastolic. The concentration of hemoglobin was 17.5 mg. per hundred cubic centimeters, erythrocytes numbered 5,170,000 and leukocytes 6,100 per cubic millimeter of blood. The sputum was negative for bacilli of tuberculosis. Breath sounds, vocal resonance and vocal fremitus were diminished on the right side. The heart was displaced to the left. The right side of the diaphragm and the liver were displaced downward. Succussion sounds tinkle, and amphoric breathing were absent, and the com test was negative. On study of intrapleural pressure, the original reading was from +6 to +1. After withdrawal of 500 cc. of air the reading was from +3 to -1.

The roentgenologist made a diagnosis of congenital cystic disease of the lung. A roentgenogram disclosed cystic destruction of the entire right lung (fig. 1), a small amount of fluid at the base of the right lung, and a small cyst at the hilus of the left lung. Bronchoscopic examination disclosed that the trachea was pushed to the left, the lumen of the right main bronchus was slightly narrowed and was collapsible with respiration. A small amount of blood was seen coming from the bronchus of the lower lobe of the right lung. Roentgenograms after injection of iodized poppy-seed oil disclosed an advanced cystic condition of the entire right lung (fig. 2).

No treatment other than restriction of activities was advised.

CASE 2—A girl, aged 5 years and 4 months, was examined in February, 1924. The family history was unimportant, there was no tuberculosis in the family. Birth had been normal. The child supposedly had had mild influenza in the third month of life and bronchitis at 18 months but she had been considered to be robust and healthy until she had reached the age of 3 years. After her third birthday she had begun to have recurring attacks of nausea and vomiting with fever. Tonsillar infection had been found and the tonsils and adenoids had been removed in March, 1921. The patient had remained well and had gained weight and strength for six months. In November, 1921, however, she progressively had lost weight and strength had had marked anorexia and gradually but steadily had become more dyspneic on exertion. This condition had persisted for one year, without pain, elevation of temperature, sweats or cyanosis. In December, 1923, because of mild respiratory infection and cough for one week, she had been taken to her physician who had made a diagnosis of spontane-

From the Division of Medicine, the Mayo Clinic. Because of lack of space, this article is abbreviated in THE JOURNAL. The complete article appears in the author's reprints.

Read before the Section on Practice of Medicine at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 13, 1934.

<sup>1</sup> Koontz, A. R. Congenital Cysts of the Lung. *Bull. Johns Hopkins Hosp.* 34: 361 (Nov.) 1925.

ous pneumothorax of the right side. Air had been aspirated eight or nine times from the right side of the thorax, supposedly from the right pleural space, without relief.

When the patient was examined at the clinic in 1924 her pulse rate was 118 beats per minute, respirations were 45 per minute and breathing was labored, but cyanosis was absent. The temperature was normal. The physical signs were those of pneumothorax of the right side. The roentgenologic report was that the right lung was completely collapsed and the heart displaced to the left. The value for hemoglobin was 68 per cent, erythrocytes numbered 4,010,000 and leukocytes 12,400 per cubic millimeter of blood. Urinalysis gave negative results and the Wassermann reaction of the blood and the Pirquet test were negative. Air was aspirated on three occasions. The first time, a positive water pressure of from 24 to 32 cm was present, the pressure became atmospheric after aspiration of 550 cc of air. At the time of the second aspiration, a negative pressure of from 2 to 4 cm was found, it became positive when the child cried. At the third aspiration, a positive pressure of 20 cm was found, and exploration of the thorax was carried out. The surgeon's report is as follows: A filmy, transparent membrane was seen beneath the parietal pleura. When it was incised an empty right thoracic cavity was found, with no trace of pulmonary tissue. When the cavity was partially filled with saline solution, at two points near the hilus some bubbling was seen, which soon ceased. These areas were lightly touched with a cautery and the incision was closed. The patient's convalescence was successful, with some formation of fluid, which was aspirated once. Even after exploration the correct diagnosis was not recognized, and the surgeon's opinion was that he was dealing with a condition of congenital absence of the right lung. A postoperative roentgenogram was made (fig 3A).

Fig. 1 (case 1).—Cystic changes involving the entire right lung. The heart and mediastinum are displaced to the left.

For the subsequent history, pathologic changes and recent thoracic roentgenogram (fig 3B), I am indebted to Dr. Birnberg to whose care the patient was returned after operation. From 1924 until February 1934, the girl developed normally, without acute illness except for one attack of what was probably acute appendicitis. There was always moderate dyspnea on exertion but otherwise she was fairly healthy. She became acutely ill, Feb. 1, 1934, with inflammatory abdominal disease, and was admitted to the hospital February 5, where immediate laparotomy was performed. Generalized peritonitis was found and the patient succumbed five days later.

At the time of this illness, the right side of the thorax was more prominent than the left, it gave a tympanic percussion note, breath sounds were distant, and fremitus was absent. The heart was displaced to the left. There were negative physical changes on the left.

At necropsy, the observations were as follows: A large, air-containing cyst filled the right side of the thorax and was adherent to the thoracic wall and diaphragm. This remained inflated when the sternum was removed. The cyst herniated across the superior mediastinum, extending well into the apex of the left pleural cavity. The cyst was found to be filled with filmy strands, like cobwebs. The left pleural cavity was empty, and the left lung was composed of three lobes. Throughout the lower lobe and lower portion of the upper lobe were numerous small areas of pneumonic consolidation. The trachea was opened and water was injected. The water did not enter the large cyst but infiltrated the right lung and wall

of the cyst in the region of the apex and filled the portion of the cyst that was in the left side of the thorax.

This explanation makes me feel that in reality we were dealing with a second cyst occupying the superior mediastinum and upper left part of the thoracic cavity, rather than a portion of the large cyst herniating across.

**CASE 3**—A married woman, aged 37, was referred to the clinic in June 1926 by Col. J. A. Wilson<sup>2</sup> after complete investigation and with a diagnosis of emphysematous cyst of the upper lobe of the left lung. This case has been reported by Colonel Wilson, who apparently was the first to induce pneumothorax for diagnosis in this condition.

On examination at the clinic, the physical changes were those of pneumothorax involving the left side. The mediastinal structures and heart were displaced to the right. We repeated Colonel Wilson's diagnostic procedure and induced pneumothorax. This clearly demonstrated the wall of the partially collapsed cyst.

**CASE 4**—A boy, aged 2 years and 4 months, was examined in November 1928. There was no history of tuberculosis in the family and the family history otherwise was unimportant. Birth had been normal, and the child had seemed normal and healthy until 18 months of age. He then had had what had been diagnosed as "stomach flu," and following this gradually had lost weight and strength, although definite pulmonary symptoms had not been noted. When 22 months old, the child had had an elevated temperature, and his mother had noted that respirations were peculiar and difficult. A physician had been called, who stated that examination then had revealed a hyperresonant note over the right side of the thorax, both anterior and posterior, with almost no breath sounds, and roentgenologic examination had given evidence of what had been assumed to be pneumothorax involving the right side. The physician had aspirated air from the right side of the thorax without giving any subjective relief. As a matter of fact, the child seemed more distressed than before aspiration. The physician sent us a roentgenogram taken a few days later, which he described as follows:

"This shows what we believed to be a stripping loose of the pleura, probably as a result of the puncture, air getting behind the needle hole and stripping the pleura away from the chest wall. This rapidly fell back into its normal position."

The diagnosis can be made with certainty on the basis of this report. This picture is identical with that produced in case 2 after thoracotomy, and in case 3 after injection of air into the pleural cavity, and must have been caused by an induced pneumothorax forcing the wall of the cyst away from the thoracic wall.

**CASE 5**—A married woman, aged 19, was examined in October 1928. Her case has been reported by Harrington.<sup>3</sup> A diagnosis of intrathoracic tumor of indeterminate etiology was made, and a large cystic tumor was removed by the transpleural route. The pathologic report was as follows: Fibrous-walled cyst, filled with clotted blood, one portion composed of salivary gland tissue. There were columnar epithelial lined ducts and fibrous tubes with lining cells closely resembling bronchial epithelium. A recent review of this specimen showed that there was complete absence of pigment. The pathologic changes warrant the diagnosis of congenital pulmonary cyst.

One year after operation the patient was reported as being alive, well and able to work every day.

**CASE 6**—Harrington<sup>4</sup> has reported this case of a married woman, aged 37. A diagnosis of infected cystic tumor of the right lung was made. Jan. 16, 1932, a large cystic mass containing about 750 cc of pus was removed, and a bronchial fistula communicating with the cyst was closed.

On pathologic examination of the specimen the wall of the cyst was found to be lined by epithelium and contained car-

tilage and all types of pulmonary tissue. Complete absence of pigment was also noted when the specimen recently was reexamined.

In September 1933 the patient was reported to be in good health.

#### REPORT OF CASES IN GROUP 2

**CASE 7**—A man, aged 43, when first examined at the clinic in 1923 complained chiefly of functional disorders. Examination of the thorax gave essentially negative results. The value for hemoglobin (acid hematin method) was 117 per cent. Erythrocytes numbered 4,980,000 per cubic millimeter of blood. The Wassermann reaction of the blood was negative. Examination

Fig 2 (case 1)—Roentgenogram made after injection of iodized oil. The patient is in the lateral position. The fluid level in the cyst is evident.

tion of the sputum gave negative results. The roentgenologists reported bronchial thickening in the upper lobe of the right lung.

The patient returned in January 1934 because of "crusting of the right cheek" for a year or more, and the history which particularly concerns the changes relative to this paper will be given now. Both parents had had carcinoma. The patient had had whooping cough and pneumonia when 4 years of age. He stated that he had always been delicate and short winded and never had been able to work or exercise as hard as his companions. He had had two attacks of pneumonia with pleurisy, at the age of 21. At the age of 31 he had had elevated temperature, had lost weight and had had some hemoptysis. He had remained in a sanatorium for three months and stated that his sputum had been positive for bacilli of tuberculosis. He had had severe influenza when he was 39 and had always had frequent respiratory infections. However, there had been little cough or expectoration in recent years.

His finger tips were moderately cyanosed. The value for hemoglobin was 175 mg per hundred cubic centimeters of blood, erythrocytes numbered 4,730,000 and leukocytes 8,500 per cubic millimeter of blood. The lungs were emphysematous, there were changeable areas of diminished breath sounds over the right lower lobe and occasional rhonchi were heard. The roentgenogram disclosed multiple annular shadows throughout both lower pulmonary fields, more marked on the right. There were also miliary calcified lesions scattered throughout the left lung (fig 4). The roentgenologist's diagnosis was multiple congenital pulmonary cysts. The cutaneous lesion of which the patient complained was diagnosed as keratosis.

The man was and had been for many years definitely dyspneic but he was not at all worried about this or interested in the pulmonary examination. Further investigation did not seem warranted.

The most remarkable fact about this case is that an individual who had had pulmonary tuberculosis repeated pneumonia, many acute respiratory infections, and apparently secondary cystic infection with progressive destruction of pulmonary tissues, did not have increasing disability.

The other five cases in this group will be reported more briefly.

**CASE 8**—A man, aged 29, was examined at the clinic in June 1933. There was no tuberculosis in the family and otherwise the family history was unimportant. The patient had had measles and whooping cough as a child, influenza at the age of 19 years, and questionable pleurisy three years previous to his examination at the clinic. Five and two years before, for a period of three or four weeks, there had been moderate cough and expectoration but never hemoptysis. No other history of respiratory infection was obtainable.

The patient had been in good general health until five years before examination, and until then he had been able to participate in any form of active sport. At that time he had begun to experience dyspnea on exertion. This had been constant thereafter and had steadily increased in severity. At the time of his examination he had been able to walk slowly for a considerable distance but not more than two blocks rapidly.

On examination, rather marked pulmonary emphysema was noted. No sputum was obtainable. The roentgenologist's diagnosis was congenital polycystic degeneration of the lungs (fig 5).

**CASE 9**—A man, aged 39, examined in November 1932, came to the clinic because of backache and made no complaints referable to the lungs. There was no history of tuberculosis in the family, and the family history otherwise was unimportant. The patient had had influenza in 1918 but no other acute illness. He had moderate palpitation on exertion. His history otherwise was essentially negative.

The observations made on examination were retraction and lagging of the left upper part of the thorax, with diminished vocal fremitus, diminished resonance and diminished breath sounds over the same area. The heart was displaced to the right. The roentgenologic report read as follows: absence of pulmonary structure of the left upper lobe, heart displaced to the right, cystic degeneration of the left lower lobe and of the region of the right hilus.

In the absence of all pulmonary symptoms, further investigation did not seem warranted.

**CASE 10**—A man, aged 38, was examined in February 1932. There was no history of tuberculosis in the family, and otherwise the family history was unimportant. The patient made many complaints. He was a heavy smoker. He stated, also, that he had had cough, palpitation and dyspnea on exertion for years but did not regard this as important.

Fig 3 (case 2)—A appearance in 1924 after thoracotomy. The outline of a balloon cyst partially collapsed as a result of induced pneumothorax is evident. The heart and mediastinum are displaced to the left. B appearance in 1934: a large cyst fills the entire right side of the thorax and a second smaller cyst is in the upper left portion of the thorax.

On physical examination, the observations referable to the thorax were essentially negative. Evidences of achlorhydria, pyuria, prostatitis, dental sepsis and tonsillar infection were discovered. The normal pulmonary markings were absent in the area of the right upper lobe and the pulmonary margin could not be defined. The roentgenologist made a diagnosis of congenital cystic degeneration.

The patient did not care to submit to the bronchoscopic investigation that was suggested. Accordingly, reduction in

smoking with a better regimen of life, and elimination of foci were advised.

#### REPORTS OF CASES IN GROUP 3

**CASE 13**—A girl, aged 10 years, was examined at the Mayo Clinic, Jan 5, 1931. The family history was unimportant, there was no history of tuberculosis. The patient had had measles and mumps and supposedly had had pneumonia at the age of 7 years, followed by left empyema, resection of a rib, and drainage. She had made a good recovery. Two months previous to her examination at the clinic, cervical adenitis had

Fig. 4 (case 7)—Old calcified tuberculous lesions in both pulmonary fields with multiple cysts throughout the lower two thirds of the right lung. The outline of one cyst shows particularly well.

been cleared up following actinotherapy. For one month she had been dyspneic on exertion. Four severe attacks had come at bedtime, after playing with her younger brother, and had consisted of severe dyspnea and cyanosis. At the onset of an attack she would scream and say she was choking. She had fallen to the floor on one or two occasions. The attacks had lasted for from forty-five to sixty minutes. She would be very tired the following day but well otherwise. She had a good appetite and digestion.

Examination disclosed a scar of old empyema drainage in the left axilla, and physical examination of the lungs gave essentially negative results. Roentgenograms disclosed partial collapse of the upper lobe of the left lung, with thickening of the interlobar and mediastinal pleura (fig. 6). A roentgenogram made three days later disclosed some expansion of the collapsed portion. The patient's temperature was 99 F, her pulse rate 108 beats per minute and her blood pressure 110 mm of mercury systolic and 78 diastolic. The value for hemoglobin was 109 mg per hundred cubic centimeters and there were 8,500 leukocytes per cubic millimeter of blood. The Pirquet test was negative, the Wassermann reaction of the blood was negative, and there was no sputum for examination.

Restriction of activities was advised, and a report received fifteen months later stated that the patient had had no further attacks of dyspnea and cyanosis. She had gained 20 pounds (9 Kg) and appeared to be in good health. Information has not been obtained during the past year, and further roentgenograms have not been obtainable.

Although the diagnosis made at the time of examination was spontaneous pneumothorax, review of the history and examinations, in my opinion, warrants a diagnosis of solitary congenital cyst of the upper lobe of the left lung. It would seem that the explanation of cessation of attacks and subsequent good health was that an imperfect communication of the bronchus with the cyst had become completely closed, without gross infection occurring.

**CASE 14**—A man aged 20, was examined first in May 1930. There was no history of tuberculosis in the family and otherwise the family history was unimportant. The patient was healthy, did all kinds of farm work and had no severe illnesses until the age of 19 years. He had pneumonia in August 1930. Convalescence was normal and he remained in good health until April 1931. At this time an acute respiratory infection developed, with general malaise, elevated temperature, cough

and expectoration, and a few days later he had a pulmonary hemorrhage. After this he felt better, but he returned to the clinic for examination ten days later.

At this time, roentgenologic study revealed dense infiltration of the lower lobe of the right lung, with a fluid level, and a diagnosis of pulmonary abscess was made (fig. 7A). The bronchoscopic examination gave negative results. The patient lived near the clinic and returned at frequent intervals. The urine was normal and the Wassermann reaction of the blood was negative. Repeated blood counts were normal, and many examinations of sputum failed to reveal bacilli of tuberculosis. In the period from May 1931 until February 1933 the patient was able to work and remained in fairly good health except for two episodes. In July 1931, for one month, there was general malaise and weakness, and some rather foul expectoration. In December 1931, after violent exertion and chilling, there was general malaise, pain in the right side of the thorax, painful respirations, and some night sweats. Physical examination at this time revealed signs of moderate effusion at the base of the right lung. These physical signs and symptoms gradually subsided, and in about a month the patient had regained his former health. Repeated roentgenologic examinations gave little evidence of change (fig. 7B), and the diagnosis made was either pulmonary abscess or cystic tumor of the middle lobe. Because of the similarity in the history and progress of this case to the history and progress in case 6, Dr. Vinson suggested that we were dealing with a congenital cyst of the right lung, probably of the middle lobe, and in February 1933, on bronchoscopic examination, a small amount of pus was seen exuding from the bronchus to the right middle lobe. Iodized poppy-seed oil was injected and entered the cyst, after which roentgenograms were made which the roentgenologists reported as giving evidence of cystic tumor of the right middle lobe. Since the iodized oil has been injected, the patient subjectively has felt remarkably well and has been able to work every day. However, I do not feel that this marked subjective improvement can be explained entirely on the basis of the injection of the iodized oil.

I believe that this case is an example of a congenital cyst which was filled with fluid, the patient remained free from symptoms until after an acute respiratory

Fig. 5 (case 8)—Diffuse cystic changes throughout both pulmonary fields.

infection in April 1931, at which time infection of the content of the cyst occurred. Surgical removal of the cyst in this case should be considered, if evidence of infection and constitutional manifestations are progressive, but is not warranted so long as the patient remains free of symptoms, as at present.

**CASE 15**—A girl aged 1 year and 3 months, was examined in December 1931.

When she was 7 months old right otitis media developed, and a diagnosis of tuberculous otitis media was made. She had seemed healthy in every other way. The Mantoux test was positive in a dilution of 1:200. Physical examination and laboratory tests otherwise gave essentially negative results. The roentgenologist reported a localized area of increased density in the right upper lobe, suggesting a cyst and calcified hilar glands. A diagnosis of probable congenital cyst was made.

The possibility that we were dealing with a tuberculous pulmonary lesion was considered, but the roent-

genologic observations were not suggestive of such a condition and the positive Mantoux reaction is explainable on the basis of the otologic changes. In the absence of all pulmonary symptoms, the lesion that most satisfactorily explains the roentgenologic changes would be congenital pulmonary cyst. It is fair to assume that we were dealing with a solitary cyst of the left upper lobe, containing fluid and without bronchial communication also, it can be assumed that there is no infection of the contents of the cyst. Further examination in this case is to be desired. Unchanged roentgenologic changes would do much to confirm the diagnosis.

Fig 6 (case 13)—Large, solitary cyst of the upper lobe of the left lung

CASE 16—A youth, aged 19, was examined in June 1932. He had had three febrile attacks, diagnosed as pleurisy, the first at the age of 6 years, the second when he was 16, and the third in January 1932, which had begun with acute tonsillitis. Aside from these illnesses, the patient's general health always had been good. Since the illness in January 1932 he had never been well.

Cough had developed, with creamy, purulent secretion occasionally blood tinged, and on two occasions, in May and July, there had been a profuse pulmonary hemorrhage.

Physical examination of the thorax gave essentially negative results. Many roentgenologic examinations were made, which sometimes disclosed a dense, somewhat circular, shadow in the right upper lobe, and at other times a fluid level was manifest. The right upper part of the thorax, posteriorly, was explored November 26. While the patient was going under the anesthetic he coughed up a very large amount of purulent material. The abscess, or cyst, was found to be collapsed and could not be removed surgically. It was entirely in the substance of the right upper lobe. Bronchoscopy was performed on two occasions in April 1933, and purulent material was again seen to exude from the opening near the bronchus to the right upper lobe. Iodized poppy-seed oil, 15 cc, was injected. The patient was again subjected to bronchoscopy September 15, and no pus could be seen. He had gained weight, had practically no cough or expectoration, was feeling very well, and had been able to work all summer.

The first diagnosis made was pulmonary abscess or cyst and later infected cyst of the right upper lobe. The possibility of its being an infected dermoid was considered, but there was never any evidence of hair in the secretion, and the marked improvement that followed spontaneous emptying of the cyst and injection of iodized oil makes me feel that it was, in all probability, a congenital cyst, asymptomatic until secondary infection occurred.

#### COMMENT

The experience related in this paper differs from that previously given. In this series, the lesions were wholly or chiefly limited to the right side of the thorax in eight cases and to the left in five. In three the lesions were bilateral and of the honeycomb type. In three of the others in which the lesions were chiefly unilateral, there was evidence of bilateral involvement. I believe that these variations are not of importance. It is probable that opportunity to make an anatomic examination

in all cases would considerably increase the percentage of cases in which bilateral lesions are demonstrable. In the series here reported ten patients were males and six were females. Of the thirteen cases in which the lesions were chiefly unilateral, the cysts contained fluid in five, and contained air in eight. In all cases the Wassermann reaction was negative and a history suggestive of syphilis was not obtained in any case. There was evidence of old healed tuberculosis in one case and of tuberculous otitis media in another. Both tuberculosis and syphilis seemingly can be ruled out as etiologic factors. Thirteen patients came to the clinic with complaints associated with the pulmonary lesions, but in three the pulmonary lesions were purely incidental.

**Symptoms**—Extensive lesions may be present with very few, or with no, symptoms. The clinical manifestations vary greatly and depend chiefly on the extent of the lesions, on their site, and on whether there is a change in intrathoracic pressure. There is no syndrome on the basis of which a clinical diagnosis can be made, but the history is nevertheless extremely important and in many instances should lead to a strong suspicion that pulmonary cystic degeneration will be found. Most characteristic of all is a history, obtained particularly with reference to infants and children, of recurring attacks of severe dyspnea with cyanosis. Such a syndrome should make one suspect that one is dealing with a pulmonary cyst under increased pressure. Miller<sup>6</sup> reported the first case of which I have been able to find a report in which a clinical diagnosis of congenital cystic lung was made. This case was characterized by attacks which the author ascribed to secondary spontaneous pneumothorax. Cautley,<sup>7</sup> however, in 1924 reported a similar case, with necropsy, and suggested the possibility that the dyspneic attacks occurred when air could enter the cyst through a valvelike opening, without equally free egress resulting in increased intrathoracic pressure. Eloesser agreed with this and stated

Fig 7 (case 14)—A large cyst at the right hilus with a fluid level in the cyst. B the same cyst two and a half years later filled with fluid.

that such attacks occurred only when an imperfect bronchial communication existed and would be absent when either a free communication or no communication at all existed. This explanation is most logical and is unquestionably correct.

When progressive dyspnea develops in adults, without apparent cause, and with or without a preceding respiratory infection, the possibility of congenital cystic degeneration of the lungs should be considered.

<sup>6</sup> Miller R. T. Jr. Congenital Cystic Lung. *Arch. Surg.* 12: 392-405 (Jan.) 1926.

<sup>7</sup> Cautley E. A Cystic Malformation of the Lung. *Brit. J. Child Dis.* 21: 138-140 (April-June) 1924.

Dyspnea is the most constant subjective complaint and in our series was present in eleven cases. In eight it was severe. Cough was present in seven cases, but in only four was there any considerable amount of sputum. Cyanosis was noted in only one case but probably was at times present in several others. Severe palpitation was a complaint in two cases. In only three cases was there any pain. In two cases there was brisk pulmonary hemorrhage, and in one there was slight hemoptysis.

The heart and mediastinal structures were markedly displaced to the side opposite the lesion in five cases. Several cases in which the reverse was true have been reported, but theoretically, with increased intrathoracic pressure, the displacement should be away from the lesion unless the mediastinum is fixed by previous inflammatory disease. The reverse is true in the presence of massive atelectasis, in this, the mechanics of production necessitate the drawing of the surrounding structures toward the lesion.

**Diagnosis**—In all cases, with all types of lesions, satisfactory roentgenologic study is a necessity in making a diagnosis of congenital cystic disease of the lungs. In many instances bronchoscopic examination, injection of opaque substances, and induction of pneumothorax may be necessary in addition. The various conditions that must be distinguished from it depend largely on the type of cystic degeneration present. With fluid-containing cysts the lesions that offer most difficulty in differential diagnosis are (1) thoracic tumor, (2) pulmonary abscess, (3) empyema, (4) dermoid cyst and (5) echinococcus cyst.

The discharge of cystic secretion may at times aid in the diagnosis, but if a cyst filled with fluid, has no bronchial communication and is lacking a fluid level it may be impossible to distinguish it from a solid tumor. In such a case, the true nature of the lesion can be determined only by exploratory thoracotomy.

A cyst (particularly if a fluid level is present) may have the same appearance roentgenologically as a pulmonary abscess. The character of the secretion may aid in differential diagnosis, but secondary infection of the content of the cyst frequently occurs, and purulent secretion from a cyst may be indistinguishable from secretion from an abscess. In such an instance bronchoscopic examination and injection of iodized oil may allow the two to be distinguished. A pulmonary abscess nearly always undergoes regression or progression whereas the appearance of a pulmonary cyst probably will remain unchanged over a long period. This fact may be a diagnostic aid. Cysts have at times been mistaken for evidences of localized empyema. A few have been reported in which the diagnosis was made only following thoracotomy.

Eloesser mentioned the fact that in empyema of this type the roentgenographic shadow is wedge shaped, with the base against the thoracic wall. In a case of pulmonary cyst, this is not so. The shadow may be circular or rectangular.

It may be impossible to distinguish a dermoid from a congenital cyst, unless teeth, bone or cartilage can be demonstrated roentgenologically, or unless hair is found in the secretion. Either finding would, of course, confirm a diagnosis of dermoid. A number of cases of echinococcus pulmonary cyst have been reported in which it was impossible to make a roentgenologic differential diagnosis from congenital cyst. They can be easily distinguished, however, by a complement fixation

test. In cases of echinococcus cyst, also, urticaria is frequent and eosinophilia will be found.

In considering air-containing cysts, the diagnostic problem is different. Bronchiectasis at times may give a history and produce roentgenologic changes not unlike those of honeycomb lung, but otherwise almost the only lesion that can be mistaken for congenital cyst of the lung is spontaneous pneumothorax. If the differential diagnosis is between bronchiectasis or congenital cystic degeneration, bronchoscopic examination and injection of iodized oil generally will show which is present.

In cases in which there are fluid-containing cysts or honeycomb lungs, physical examinations are of little or no diagnostic value. In cases in which there are large balloon cysts, routine physical examinations will give results identical with those in cases in which spontaneous pneumothorax exists. However, in spontaneous pneumothorax, a well defined outline of the margin of the collapsed lung should be visible, and in cystic degeneration it is not.

Pollock and Marvin stressed the point that the walls of air-containing cysts appear roentgenologically as curving, linear shadows, whereas in pneumothorax with associated pleural adhesions the linear shadows are straight. If a bronchial communication exists, injection of iodized oil generally demonstrates successfully the outlines of the cyst. If no communication exists, however, a large balloon cyst can in some instances be differentiated from pneumothorax only by injecting air into the pleural cavity. The resulting roentgenogram, showing the outline of the partially collapsed cyst forced away from the thoracic wall, is absolutely diagnostic. I believe that Colonel Wilson was the first to employ this diagnostic measure. At the clinic we repeated the procedure in his case, and it was of value in two other cases in our series.

**Treatment**—Some observers have reported improvement following bronchoscopic aspiration followed by injection of iodized oil. A few other observers have reported cures following extirpation of a fluid-containing cyst. In two cases of our series Harrington removed such cysts with apparent cure of the disease.

In two cases in which there were infected cysts communicating with a bronchus, marked subjective improvement followed bronchoscopic aspiration and injection of iodized oil. A third such case became asymptomatic following spontaneous rupture and evacuation of the cyst.

In one case, characterized by recurring attacks of cyanosis and dyspnea, the attacks subsided, presumably as a result of complete bronchial occlusion having occurred spontaneously. In one case, the patient remained in good health for ten years following thoracotomy, at which time the bronchial orifices were cauterized. This procedure appears to have resulted in complete bronchial occlusion.

In three cases, few or no symptoms resulted from the cystic pulmonary changes, and in six cases the symptoms were progressive, and no attempts at treatment were instituted.

In most of the cases that have been reported, which were characterized by increased intrathoracic pressure (dyspnea and cyanosis), repeated aspirations or the institution of permanent thoracic drainage was necessary as a life-saving measure. In three of our series, and in the other cases reported in the literature, in which increased intrathoracic pressure did not occur, benefit was not derived from aspiration of air from the thoracic cavity.

## SUMMARY AND CONCLUSIONS

Congenital cystic degeneration of the lungs is an uncommon disease, but it occurs much more frequently than has been suspected. With modern diagnostic methods, a roentgenologic diagnosis should be made in a high percentage of cases. Secondary pulmonary infection is the greatest potential danger to which the patients are subjected. Patients who have no bronchial communication are safer and the disease is less likely to progress than if such a communication exists. In cases in which there is a bronchial communication an attempt to produce complete bronchial occlusion is a proper procedure. Complete extirpation of fluid-containing cysts has given excellent results in a number of cases. A number of patients who had infected cysts, with bronchial communications, have been greatly benefited by bronchoscopic aspiration followed by injection of iodized poppy-seed oil. This treatment should be considered in cases of this sort. Diffuse, bilateral cystic degeneration of the so-called honeycomb type is not benefited by any form of treatment.

## ABSTRACT OF DISCUSSION

DR L. J. MOORMAN, Oklahoma City. This condition is more common than is realized. Dr. Wood has made obvious the wide variation of symptoms and the pathologic changes. These variations suggest grave diagnostic difficulties. The picture as visualized through the history, the physical examination and the roentgen and bronchoscopic observations is often colored by secondary infections and various postnatal respiratory influences, especially variations in intrathoracic pressure. If the cysts do not communicate with the bronchi or if there is free communication without secondary infection there may be no symptomatic evidence of the disease. If the cysts and the bronchi communicate with valvelike constrictions at the point of communication distressing and even fatal dyspnea and cyanosis may develop. In other cases escaping early fatal intrathoracic pressure the symptoms may range from those of a mild bronchitis to those found in cases of advanced pulmonary tuberculosis or in nontuberculous suppurative pulmonary infections. With such a marked variation in clinical and pathologic manifestations one may expect the physical signs to cover a correspondingly wide range. Roentgen studies present similar diagnostic difficulties. The existence of cough, dyspnea and cyanosis from the time of birth or for at least a period of years, with a history of periodic exacerbations of respiratory symptoms and signs, should lead one to suspect the presence of this condition. Repeated sputum examinations negative for tubercle bacilli support this suspicion. Such a history supplemented by a careful physical examination should enable one to eliminate the various pulmonary conditions that may be confused with this disease. A careful study of good stereo x-ray films may be the final diagnostic stroke. In case polycystic disease is present even though there may be areas of opacity as a result of atelectasis and associated infection the films may reveal a designless network with graceful lines falling across large areas otherwise practically devoid of lung markings. These fine lines do not correspond in location, direction or general appearance to the uniform tracings of the normal bronchial tree or those occasionally appearing as a result of thickened pleura at the interlobar fissures. In certain cases continued observation, bronchoscopic studies and injections of iodized oil may be required to make the diagnosis.

DR JAMES L. DUBROW, Des Moines, Iowa. In the last twenty months I have seen three cases of cystic disease of the lung. Reviewing the literature I noted that most of the cases of congenital cyst of the lung may be grouped as follows: 1 Symptomatic. (a) Those presenting symptoms and signs simulating valvular pneumothorax wherein the mechanism is that of obstructive emphysema. This type usually occurs in children. However, Wilson reported a case of obstructive emphysema in an adult in whom periodic attacks of dyspnea necessitated the aspiration of air from the thoracic cavity with

apparent symptomatic improvement. That he was dealing with a congenital cyst was evidenced by the fact that after the induction of artificial pneumothorax the visceral pleura was outlined. In a similar case there was absence of lung tissue on the right side simulating spontaneous pneumothorax. After the induction of artificial pneumothorax the visceral pleura and the intrapulmonary hollow spaces were outlined. (b) Cystic degeneration of a whole lung simulating atelectasis. (c) Congenital bronchiectasis simulating the acquired form. In a case in which there was a dense shadow covering the left lung, with elevation of the left dome of the diaphragm and retraction of the heart to the left, injection of iodized oil revealed grape-like sacculations in the left lung and no outline of the small bronchi of the lower lobe and those of the peripheral zone. The appearance of this lung after bronchography suggested bronchial maldevelopment rather than bronchiectasis. 2 Asymptomatic. (a) Solitary or multiple cysts with an open bronchial connection. The following points are of value in diagnosing congenital cyst of the lung: 1 The compressed lung cannot be seen fluoroscopically or roentgenographically. 2 Thoracentesis with injection of iodized oil through the center of the apparently structureless space on subsequent radiographic examination shows the bulk of the iodized oil retained at the point of injection. 3 Bronchography demonstrates bronchial maldevelopment with no outlining of the bronchioli. 4 Diagnostic pneumothorax outlines the visceral pleura.

DR J. J. SINGER, St. Louis. I have seen several cases of lung abscess with the bronchoscope and have even operated but found that the cyst walls did not collapse or the walls of the cavity did not collapse. It was after reviewing these histories that I suddenly discovered I had more cases of congenital cysts than I thought. The important part in the discussion is what to do for the cyst. The cyst wall because it does not collapse is pushed over *en masse* as a large sac when it ruptures into the pleura in that way displacing the mediastinal contents and producing the severe dyspnea. I want to show what may be done in the treatment of a polycystic lung. I refer to the induction of a pneumothorax. This was discovered by the following accident. A child had had a pneumothorax and fluid developed in the pleural space and the cyst wall. When the fluid was absorbed symphysis of the two pleural leaves occurred binding the cyst wall to the chest wall, so that no leakage of air into the pleura could take place, and the child became clinically well. I have attempted to treat a few cases that way. I had one case in which the opening into the cyst was not made evident by bronchoscopic examination or by injection. There may exist a connection of cysts through the trachea into the opposite lung. Unfortunately, in some of these cases there is no opening large enough between the trachea and the cyst wall as Dr. Wood pointed out. In one case he cauterized the connection. I think that is an excellent idea and have attempted that in one case.

DR HARRY G. WOOD, Rochester, Minn. I wish to thank all of the men for their discussion and to add that Dr. Dubrow may have misunderstood me. In my experience, when there was displacement of the heart and mediastinum it was always away from the side in which the greatest pathologic change existed and not toward it although some cases have been reported in which the reverse was true. I believe this is caused by an associated atelectasis and not by the cystic disease.

Graham Lusk at Twenty-Five.—When I was twenty-five years old I found myself the head of a department of physiology at a salary of \$300 per annum with an allowance of \$150 annually for apparatus. The department consisted of one room in the old building at 150 York Street. Here Dr. L. C. Sanford and I brought up some pigs on the bottle and here the phlorhizin work on rabbits was started. I did all the cleaning and I mopped up the floor myself. Later a new laboratory building was built in the yard of which I had an entire floor and at last I had some one to wash dishes. Here phlorhizin brought new information from dogs.

I never had an assistant while I was in New Haven. My salary and that of the other professors had been raised to \$500 before I left. In New Haven my life was one of peace for seven years.—Lusk, Graham, quoted by Light. A. E. Graham Lusk, *Yale J. Biol. & Med.* 6:487 (May) 1934.

## THE PATHOLOGIC CHANGES OF THE ST LOUIS TYPE OF ACUTE ENCEPHALITIS

HOWARD ANDERSON McCORDOCK, M.D.

WILLIAM COLLIER, M.D.

AND

SAMUEL H. GRAY, M.D.

ST. LOUIS

[EDITORIAL NOTE.—This paper, together with the papers of Dr. Eschenbrenner, Drs. Bredeck and Zentay and Dr. Jones, which follow it, concludes the symposium on epidemic encephalitis. In the last issue were published the papers of Dr. Neal, Drs. Leake, Musson and Chope, Drs. Muckenfuss, Armstrong and Webster, and Dr. Hempelmann.]

A large number of autopsies was secured during the recent St. Louis epidemic of acute encephalitis, the result mainly of the cooperation of the various public health offices, the general medical profession and the public. Sufficient material was obtained for a complete study of sixty-three cases. The thoracic and abdominal organs and portions of the spinal cord were examined in addition to the brain in about 90 per cent of the autopsies. An adequate neuropathologic study of all this material has not yet been accomplished, but a few representative cases have been studied in detail and a sufficient number of sections from the others have been examined to obtain a fair understanding of the pathologic alterations in this type of encephalitis. The essential pathologic process is an acute non-suppurative inflammation of the central nervous system characterized by severe vascular congestion with occasional petechial hemorrhages, cellular infiltration of the nervous tissue and meninges with mononuclear cells, and degenerative changes in the nerve cells.

Fig. 1—Perivascular cuff of lymphocytes about a small vein in the pons.

### GROSS PATHOLOGIC CHANGES IN FATAL CASES

The only constant macroscopic alteration in the central nervous system was vascular congestion of varying degree. Every brain showed obvious congestion of the meningeal as well as of the intracerebral blood vessels. Petechial hemorrhages were found in the pia-arachnoid in the more severe examples of the disease. Cross-sections through the fresh brain revealed

a light salmon-pink coloring of the gray substance in every instance in which the superficial vascular congestion was marked. In severe cases the entire cortex, as well as the gray substance of the midbrain, pons and spinal cord, instead of presenting the normal gray, was bright pink. In the usual case, however, this pinkish discoloration was blotchy in distribution, appearing as scattered patches in the cerebral cortex, basal nuclei, brain stem, pons or spinal cord.

The cerebrospinal fluid was noticeably increased in amount at twenty autopsies, and the clinical records of these cases showed that repeated spinal punctures had

Fig. 2—Focal collection of cells (glial nodule) in cerebrum.

not been performed during life. The fluid was always clear and an exudate was never apparent in the meninges.

The brain tissue presented an increased softness due to edema in many of the more acute cases. Thrombosis of venous sinuses or other blood vessels was never observed.

### MICROSCOPIC CHANGES

1 *Congestion and Hemorrhage*—Congestion of the meningeal or of the intracerebral blood vessels could be found in some of the sections from every case. The pink coloring of the gray substance that was apparent to the naked eye revealed, under the microscope, the most intense congestion of the vessels down to the finest capillaries. In twenty instances the vascular congestion was intense and in each of these small subarachnoid hemorrhages were found as well as an occasional extravasation of blood into a perivascular space in the substance of the brain or a petechial hemorrhage in the brain tissue.

2 *Cellular Infiltration*—Two types of cellular infiltration were found. One was the typical perivascular accumulations of lymphocytes, the other diffuse or focal collections of various types of inflammatory cells. In all but two of the sixty-three brains examined collections of mononuclear cells were found surrounding the smaller vessels, forming the perivascular cuffs (fig. 1) that so commonly are observed in various diseases of the nervous system. The cells were usually confined to the Virchow-Robin space and consisted principally of lymphocytes with an occasional plasma cell and large mononuclear phagocyte.

In addition to the almost constant perivascular cuffing, the more severe cases also showed cellular

infiltration which did not bear any apparent relation to blood vessels. Small focal collections of inflammatory cells (fig 2) were present in the cerebral cortex, midbrain, pons and medulla. Most of the cells comprising these foci were apparently derived from the microglia, but also a few plasma cells and polymorphonuclears could occasionally be identified. The remains of a degenerated nerve cell could often be found at the center of one of these cellular foci, and this process of neuronophagia (fig 3) was marked in all cases in which the cellular infiltration was extensive. In brains showing the most intense reactions, large areas of diffuse cellular infiltration (fig 4) were often found in the basal nuclei or in the pons and medulla.

**3 Nerve Cell Degeneration**—In almost every case, some degree of pathologic change was found in the nerve cells. Slight changes such as eccentricity of the nucleus, swelling of the nucleolus and perinuclear chromatolysis were common. All cases exhibiting extensive cellular infiltration were prone to show more marked degenerative alterations in the nerve cells (fig 5), and of these the most frequent were shrinkage of the cell body with darkly staining, homogeneous cytoplasm, pyknosis of the nucleus or almost complete disappearance of the cell, producing a faint shadow-like remnant.

Typical inclusion bodies such as are associated with many virus diseases were not found in the nerve cells, although swollen nucleoli in degenerating cells frequently stained red with eosin or fuchsin. These acidophilic nucleoli resembled inclusions and might erroneously have been regarded as such were it not

Fig 3—Proliferation of microglial cells about degenerating nerve cells (neuronophagia)

for the fact that serial sections did not reveal a normal nucleolus in these cells and that similar red staining nucleoli have been found in a variety of diseases affecting the brain.

**4 Cellular Infiltration of Meninges**—Increased numbers of cells were found in the meninges in about three-fourths of all the brains examined (fig 6). The cells

were for the most part lymphocytes, with a few plasma cells and large mononuclears. A purulent meningeal exudate was never encountered.

#### DISTRIBUTION OF LESIONS IN NERVOUS SYSTEM

The vascular congestion was fairly uniformly distributed throughout the nervous system. The pink discoloration of the gray substance due to capillary congestion was not confined to any particular area but

Fig 4—An area of diffuse cellular infiltration extends diagonally across the picture. Two large vessels have perivascular cuffs.

was most frequent in the pons and medulla. Both horns of the spinal cord were bright pink at all levels in two severe cases in which the entire cord was removed.

The greatest concentration of lymphocytes in the meninges was usually found at the base of the brain.

Both the intensity and the distribution of the cellular infiltrations presented great variations in the different cases. The most severe reactions were found in the brains of those who died early in the epidemic. In these, inflammatory foci were present in all regions of the brain and often in the upper cord. Large areas of diffuse infiltration with marked nerve cell degeneration also occurred in these early severe cases.

When numerous the perivascular cuffs were found in all parts of the brain, but when few in number they usually were present in the pons.

No particular area consistently showed degeneration of the nerve cells, nor did the severity of the cellular infiltration or the vascular congestion seem to bear any definite relation to this change. Damaged nerve cells were often found in the cortex but were more frequent in the pons, basal nuclei and medulla. The cells of the nuclei of the cranial nerves were seldom affected except in a few instances when very severe reactions were widespread throughout the brain.

Cellular foci and degenerative changes in the nerve cells were found in the cervical and lumbar regions of the spinal cord in a few cases. The two horns were equally involved and the selective destruction of the anterior horn cells so characteristic of anterior poliomyelitis was not apparent.

## CHANGES IN OTHER ORGANS

Chronic changes in the heart, vascular system and kidneys were common, because most of the autopsies were performed on the bodies of older persons. Bronchopneumonia was the most frequent terminal process.

About one third of the cases showed an acute change in the kidneys which was apparently related to the

Fig 5—Degenerative changes in nerve cells of the pons. The three black irregular objects above the letter *D* represent shrunken, degenerated nerve cells which stain a homogenous dark red with eosin. The nuclei no longer take a stain with basic dyes.

disease itself and not to some antecedent condition. This consisted of swelling and congestion with a hemorrhagic pyelitis. Microscopically there was cloudy swelling and necrosis of the tubular epithelium, with distention of the glomerular vessels and occasionally a small amount of blood in the glomerular space or in the tubules.

Intranuclear inclusions have been observed in about one fourth of twenty-five kidneys that so far have been thoroughly examined. These were found in the epithelial cells of the convoluted tubules and of Henle's loop. Their significance in this type of encephalitis has yet to be determined; they are not, however, present in routine material from other diseases.

## BACTERIA IN THE NERVOUS TISSUE

Small abscesses were present in the brain tissue in three cases and were amply explained by the presence of primary suppurative processes in other organs. Bacteria were demonstrated by Gram stains in the brain tissue in each of these three cases. These were the only instances in which bacteria were found in the nervous tissue with any signs of a cellular response to their presence, although bacteria that were the result of postmortem invasion were observed in several cases in which autopsy was deferred for a long time or in tissue that had been transported from a distant hospital before fixation.

Bacteria or other micro-organisms were not consistently found and this was in keeping with the negative character of cultures of the spinal fluid and of the brain emulsion used for experimental purposes.

## COMPARISON WITH OTHER TYPES OF ENCEPHALITIS

The early severe cases that first came to autopsy showed most intense inflammatory reactions in many different parts of the brain. A comparison of these

with material from fatal cases of the lethargic type<sup>1</sup> of von Economo and with published descriptions of this condition revealed several striking differences. The lesions of the two types were qualitatively similar but showed marked differences in degree and distribution. The severe cases of the St. Louis type differed from the lethargic type in the following respects:

1 The meninges showed more intense infiltration with mononuclear cells than usually was found in the lethargic type.

2 Degenerative changes in the nerve cells were more frequent and neuronophagia was more marked.

3 The inflammatory foci were more widespread throughout the brain, often occurring in great numbers in the cerebral cortex, and were not restricted to the midbrain or basal nuclei.

4 The cranial nerve nuclei, especially the third, rarely showed degenerative changes such as are frequent in the von Economo type.

5 There was more extensive involvement of the spinal cord in the St. Louis type.

As the epidemic progressed, the lesions became less intense and not so widely scattered. Many of the milder cases showed about the same degree and intensity and a similar distribution in the midbrain, basal nuclei and pons as was seen in the lethargic type. Therefore, as far as these milder cases are concerned it is impossible to differentiate them with any degree of certainty from the lethargic type on the basis of the pathologic lesions alone.

The lesions described by the Japanese in their type B encephalitis are similar in many respects to those of the St. Louis type. The intensity of the meningeal infiltration, the frequency and distribution of the focal collections of cells, the absence of cranial nerve nuclei

Fig 6—Infiltration of meninges with lymphocytes and large mononuclear cells. A small strip of cortex extends across the bottom of the picture.

involvement, and the frequent presence of lesions in the spinal cord, are strikingly similar in both of these types. The areas of softening (associated with the disease) and the retrogressive changes in the cellular foci (glial nodules) which they described were infrequent in our material.

<sup>1</sup> Greenfield, J. G. *Brit. M. J.* 2: 782 (Nov. 20) 1920. 2: 535 (Sept. 24) 1927. Boyd, W. *Quart. J. Med.* 18: 153 (Jan.) 1925.

### SUMMARY

The essential pathologic process in the St. Louis type of encephalitis is a nonsuppurative inflammation of the nervous system characterized by intense vascular congestion, cellular infiltration, and degenerative changes in the nerve cells.

Severe examples of the disease which closely resemble the Japanese type B<sup>2</sup> can readily be distinguished from the lethargic type, although the milder cases cannot be differentiated from the latter on the basis of the pathologic lesions alone.

## THE ENCEPHALITIS EPIDEMIC IN ST. LOUIS CITY AND COUNTY, 1933

### PROGNOSIS

ANDREW B. JONES, M.D.  
ST. LOUIS

Increasing age influenced prognosis more than any other single factor, the greatest percentage of mortality occurring in the aged, as shown in the chart. The presence of preexisting organic diseases such as nephritis, heart disease or debilitated states greatly increased the chances of a fatal termination.

No single clinical sign or symptom considered alone was of much prognostic significance. Absent reflexes and retention of urine indicated a fatal outcome regardless of the duration of the illness, age of the patient, or number of cells in the spinal fluid. The development

Mortality rate per hundred thousand of estimated population

of rales in the chest, bronchopneumonia and the presence of albumin, casts and blood in the urine were of grave prognostic significance.

The duration and severity of the illness were extremely variable. The mild or abortive case lasted for two or three days, the ordinary case from seven to fourteen days, the chronic case from a few weeks to months. In a very small percentage of the aged there existed for days, weeks or months a state of more or less clouding of consciousness characterized by apathy or unconcern during the daytime, spontaneous whimpering or crying at nights, and in some cases the night prowling

of the arteriosclerotic and those with senile dementia. Not infrequently, neurasthenic-like states followed immediately on the subsidence of the acute disease, persisting for weeks and months. Almost without exception, these neurasthenic-like states occurred in persons with a neurotic diathesis.

Extrapyramidal tract signs developed during the febrile stage in a very few cases, together with varying degrees of clouding of consciousness with spontaneous laughing and crying, unintelligible speech and periods of anxiety and apprehension, dragging on for many months, the majority making a complete recovery and the remainder still showing signs of improvement. The temperature of this group may have returned to normal and remained practically normal after about the second week. When death occurred it was the death of an overwhelming toxemia. More than 50 per cent of the 221 deaths occurred between the first and seventh days of the illness (table 1).

TABLE 1—Interval Between Onset and Death

Interval	Deaths
1 day	2
2 days	10
3 days	11
4 days	23
5 days	24
6 days	2
7 days	16
1 week or less	111
1 to 2 weeks	62
2 to 3 weeks	10
3 to 4 weeks	8
4 to 5 weeks	5
5 to 12 weeks	5
Onset unknown	11
Total	221

An elaborate follow up of the patients who recovered was undertaken by the Public Health Department of the City of St. Louis. This survey was begun early in December 1933 and completed the first of March 1934, comprising a total of 375 cases in the city of St. Louis. A copy of the tabulated symptoms present after the illness is presented in table 2.

TABLE 2—Follow-Up Tabulation of Patients Who Recovered

Symptoms Noted in Follow Up Reports	No. of Cases
Headaches	100
Pains in various parts of the body	90
Restless in sleep or sleepless	86
Tremor of hands or other part of body	72
Nervous	69
Impaired vision or pain or burning of eyes	66
Dizziness	56
Forgetful or confused	54
Reflexes hyperactive or sluggish	48
Personality changes—more excitable or irritable or more sullen or melancholy	45
Loss of strength weakness	29
Easily fatigued	24
Speech affected—slower, stammering or jerky	23
Drowsy lethargic	22
Paralysis of face or other part of body	21
Increased perspiration	19
Diminution of hearing	14
Impairment of ability to concentrate	13
Withdrawal from social contact	4
Protrusion of eyelids	3
Rapid decay of teeth	1
Difference in size of two legs	1
Knee bending habit	1
Weakness in legs	1
Fits	1
Postencephalitic involvement of cerebrum out of head most of time	1

In my own private cases and the cases of a number of my colleagues, in the aggregate a sizable number, recovery was complete, without residuals of any sort. Therefore, I think it is safe to say that this table is inaccurate and misleading.

## THE TREATMENT OF ENCEPHALITIS IN THE ST LOUIS EPIDEMIC OF 1933

JOHN W. ESCHENBRENNER, MD  
ST LOUIS

Herein is presented the treatment and care developed during the observation of 348 cases of epidemic encephalitis at the St. Louis City Isolation Hospital last summer. This group of cases of epidemic encephalitis descended on us with surprising rapidity. We were at a loss to supply any specific treatment because our knowledge of the treatment of this type of epidemic encephalitis was limited. It was thus necessary to resort to symptomatic treatment based on clinical experience with similar conditions. The toxic encephalitis that follows the contagious diseases and acute infections was the most similar condition. In presenting the treatment of encephalitis, I wish to call to mind that many of these patients, adults and children, had very mild symptoms, the course of the disease was very short, there were almost no complications in these mild cases, and therefore very little therapy was required. The most of the following deals with the more severe types of cases and those that were complicated.

As is true in other contagious diseases and in neurologic conditions in which the patients are in stupor or coma and are sometimes incontinent, good specialized nursing care is important. Graduate nurses were therefore delegated to the care of these patients. All the patients were given bed rest, a soft diet and forced fluids.

With the knowledge that in the acute stage of the disease there is an acute diffuse inflammatory reaction in the brain tissue and that the symptoms were probably due essentially to cerebral edema and increased intracranial pressure, the treatment instituted was designed to relieve this condition mechanically. This consisted in the use of spinal punctures and hypertonic dextrose solution intravenously. For the relief of symptoms and as a part of our diagnostic methods, a spinal puncture was done on admission on all patients. Those who had increased pressure in the fluid usually were given some relief of their discomfort. After the first lumbar puncture, the spinal fluid pressure was usually not sufficiently increased to warrant additional spinal punctures as a routine. However, when indicated by more marked signs of meningeal irritation or further symptoms of increased intracranial pressure, such as headache, stupor, vomiting or convulsions, a second spinal puncture was done. The spinal fluid was usually withdrawn until the pressure became normal, amounting to from 10 to 60 cc.

Hypertonic dextrose solution intravenously was given as a routine to nearly all patients. This was given as a 10 per cent solution, 750 cc. to the adults and correspondingly smaller doses to the children. This was given daily until after the severe part of the disease was past.

Those with severe signs of cerebral edema were given 50 cc. of 50 per cent dextrose solution intravenously every twelve to twenty-four hours. This was found to be most efficacious in some cases. Fluids were forced

on all the acutely ill. In the more stuporous patients it was necessary to resort to the use of a nasal tube for feedings. In the dehydrated patients, saline solution was administered subcutaneously. Though most of the patients were stuporous, some were exceedingly restless and required large doses of sedatives.

The hyperpyrexia that was present in many of the acute cases was treated with hydrotherapy, several ice bags being applied continuously to the head and body and tepid sponge baths and alcohol rubs being given every four hours. The ice bags to the head relieved the headaches considerably.

We found that the constipation, sometimes rather obstinate, was relieved better with the saline laxatives, combined with enemas. We used drastic saline purges when the stupor was more marked in an effort to further reduce the cerebral edema. Diarrhea, a less frequent complication, was controlled by the use of camphorated tincture of opium and bismuth subnitrate in fairly large doses.

We were particularly watchful for retention of urine in the women and in the older men. When present, usually it did not recur after one or two catheterizations but sometimes was of long enough duration to necessitate the use of a retention catheter for several days. In those cases we were more likely to find pyelitis or cystitis and we accordingly treated them with alkalis, alternating every several days with acids combined with methenamine.

Various other intravenous and serum medications were tried in the acute stage but were found to have little effect on the clinical course of the disease. The drugs used intravenously were arsphenamine, quinine and mercurochrome, but no beneficial effects were observed. Rosenow's encephalitis serum was used in several cases. Blood transfusions were given to other patients but seemed to have no effect on the clinical course of the disease unless complicated by bronchopneumonia. Because the blood of convalescent patients has been proved to contain neutralizing substances for the specific virus of the disease, results were expected from the use of convalescent serum in the treatment of the acute stage. However, as in other virus diseases, such as measles, convalescent serum was found to be of little value. The use of convalescent serum in exposed individuals was not indicated, because of the paucity of more than one case of encephalitis in a family.

In the acute stage of the disease, bronchopneumonia was the most frequent complication and was treated according to the individual indications. The majority were given inhalations of a mixture of 30 per cent carbon dioxide in oxygen for ten minutes every two hours. Fifty per cent dextrose solution was given intravenously every six to twelve hours in an attempt to reduce the congestion of the lungs. As in pneumonias complicating other diseases, the patient's position was changed frequently. The toxic patients were given repeated small blood transfusions. We felt that this was helpful in some cases. The older age group of patients with bronchopneumonia, showing signs of myocardial decompensation, were digitalized and then a maintenance dose was continued.

Delirium tremens, another complication occurring during the acute stage of the disease and usually in the young men, responded readily to large regular doses of paraldehyde.

Uremia was next to bronchopneumonia in incidence and seriousness but occurred late in the disease, usually

when a patient was apparently improving and over the acute signs of encephalitis. These patients were treated by forcing fluids by mouth and parenterally to the extent of 5,000 cc in twenty-four hours. Again we favored the use of dextrose intravenously.

After the acute stage was over, some of the more severe cases were followed by a mild Parkinson's syndrome. For this we gave phenobarbital, sometimes continued in fairly large doses. The greater percentage of these patients recovered from the syndrome. The other complications, much less frequent in incidence, were taken care of symptomatically.

Encephalitis is essentially a self-limited disease. Considering the fact that the Isolation Hospital received more moribund cases and that our mortality rate was practically the same as that for the city at large, I think that we can feel that the foregoing symptomatic treatment was of value.

It was fortunate, in view of the fact that specific treatment was not available, that in most cases the recovery from encephalitis was rapid and apparently without residual effects. In analyzing the results of the treatment and the mortality rate, it is more gratifying to find that the deaths were in individuals who have an exceptionally poor prognosis in the event of any illness because of various preexisting conditions.

Isolation Hospital, 5600 Arsenal Street

#### HANDLING OF THE ST LOUIS EPI- DEMIC OF ENCEPHALITIS

JOSEPH F. BREDECK, MD, DPH

Health Commissioner

AND

PAUL J. ZENTAY, MD

ST LOUIS

The handling of the St. Louis epidemic of encephalitis presented a novel situation, as we were dealing with an entirely new disease not observed previously in this country. Because of this fact we had to devise our own plans and could not rely on any precedent or previous experience. No originality or anything startling is claimed in this presentation. We maintain only that the situation was promptly recognized and accepted and rational public health measures were introduced immediately. An adequate organization was set up in the shortest possible time and the health division took and maintained the leadership in all phases of the emergency.

As soon as the first few cases were diagnosed at the St. Louis Isolation Hospital, it was evident that we were dealing with an unusual kind of encephalitis suddenly appearing in epidemic form. Although less than twenty cases were hospitalized at the time and all of them came from St. Louis County, we anticipated, as it seems, correctly, that an extensive epidemic was threatening the St. Louis metropolitan area. At that time, of course, we could not foresee that more than a thousand cases would be reported in less than two months.

On the very first day after the clinical and public health diagnosis was established, a statement was issued informing the public and the medical profession of the existing situation. Steps were immediately taken to

establish a public health organization that would be able to cope with the problem. A few words concerning the political set up in St. Louis and St. Louis County are necessary in order to throw some light on the difficulties that had to be overcome at the beginning of the epidemic.

St. Louis City is an independent political unit and has absolutely no political ties with the surrounding territory of St. Louis County. It is also situated on the eastern boundary of the state of Missouri, and the metropolitan area includes two adjoining counties of the state of Illinois. It is evident that, in case of an epidemic involving this area, success can be secured only if some kind of inclusive organization can be built up and uniform regulations can be adopted. This was still more true in the case of an unusual public health problem never seen before.

Such a public health organization was conceived by us long before the beginning of the emergency, but under the pressure of the rapidly spreading epidemic it was put into effect within the shortest time possible. The St. Louis Metropolitan Health Council was called into existence in less than four days after the outbreak of the epidemic and it was completely organized and functioning in less than a week after the first case of encephalitis was reported. Its purpose was to bridge the existing political gaps and eliminate inevitable conflicts of authority and to work out a harmonious cooperation between the various public health units in the metropolitan area. It was a consultative body, including in its membership all the constituted health officers and other public health workers and also many physicians and others who were interested in the problem of encephalitis. It met according to needs and through its prestige and through the work of its committees made the position of the health officers infinitely easier. Two important committees were appointed at the very first meeting. These were the Committee on Rules and Regulations and the Committee on Scientific Research. The Committee on Rules and Regulations devised all the necessary public health regulations and submitted them to a meeting of the council. The result of its work was that the same form of procedures was followed by all health officers in the entire metropolitan area. The value of this is perfectly clear, particularly since under the unusual circumstances there might have been many contradictions, or at least disharmonies, between the regulations of the city health division and the other health units. The same committee also recommended the use of certain blank forms in field investigations and outlined a form for clinical observations for the various hospitals.

The Committee on Scientific Research had as its main purpose the centralization of all scientific work in the hands of laboratory workers particularly interested in this type of research. All available autopsy material was carefully preserved and handled under the supervision of this committee.

The two schools of medicine of Washington University and St. Louis University cooperated in a splendid manner. Washington University School of Medicine concentrated chiefly on the study of etiology (evidently a virus). Laboratory experiments on the various animals were done in the laboratories of Washington University School of Medicine. St. Louis University School of Medicine was mainly interested in the clinical study of the disease.

The early and complete centralization of the research work by the committee brought most satisfactory

results, which progressed even beyond our boldest expectations

Later on two more committees were added to the organization of the Metropolitan Health Council. They were the Committee on Follow Up and the Committee on Scientific Publications.

The Committee on Follow Up was and is at present interested in the after-effects of the disease. It devised a follow-up questionnaire and organized the work of reexamination of patients for the first time approximately four months after the onset of the disease. The follow-up work was to have been continued every four months and every six months for the next year. The value of such an intensive study is evident, because, without such careful follow up, knowledge of the sequelae of epidemic encephalitis will never be obtained.

The Committee on Scientific Publications brought together in a community enterprise all those who were interested in the study of the epidemic and at the present time a monograph is in the press and will be published by the U S Public Health Service about July 1. This monograph will give a comprehensive picture of the entire problem as seen in the St. Louis epidemic and we hope it will be an unusual contribution of St. Louis medicine to American medical literature.

The public health regulations adopted by the Metropolitan Health Council were as careful and at the same time as lenient as the situation warranted them. We tried to impose as little inconvenience on the families as possible. No quarantine was established, only isolation was insisted on. No placarding was done. General hospitals were opened for cases of encephalitis. The only demand was for careful technic of isolation. Whenever the number of patients justified it, separate floors were opened for encephalitis patients. The isolation period was arbitrarily set at three weeks, but patients were often released from the hospital before this period if home conditions were such that isolation was possible there. The public schools were opened at the regular time. No restrictions were put on public gatherings or theaters. The most difficult problem for the Metropolitan Health Council was to prevent a panic and forestall unnecessary procedures that were not warranted by actual scientific facts. All kinds of fantastic suggestions were made by medical men and the public, and it was not an easy job to stay on strictly scientific grounds.

Ideal and satisfactory cooperation existed from the beginning to the end of the epidemic between the Metropolitan Health Council and the U S Public Health Service. The presence of the scientists sent by the Surgeon General to St. Louis was an important factor in steadying the situation. The untiring efforts of the Public Health Service scientists brought many valuable contributions in the scientific research work.

All facilities of the Metropolitan Health Council and of all the hospitals were thrown open to all visitors, who came from far and near.

The publicity work was carefully controlled by the Metropolitan Health Council. All information to the press was given out through the office of the secretary of the council. The daily press of St. Louis and the national and international news agencies represented in the city were most cooperative and were always willing to submit copies for correction. If any incorrect or distorted information appeared, the source of the news was not at fault but rather the sensational headlines or other outside influences. Complete frankness charac-

terized the policy of the health council. Daily bulletins were issued and mailed to every member of the council showing the number of new patients and the number of deaths reported to the various health departments. We feel that, owing to this complete frankness, a panic which otherwise might have prevailed was prevented.

The experiences of the St. Louis epidemic will be, we feel, an interesting and valuable contribution to public health work and also to clinical medicine and laboratory research. Looking back on the problem from a wider perspective, as it is possible almost eight months later, we may state that more was accomplished in many ways, particularly toward unraveling the problem of encephalitis, than it was even dared to hope for at the beginning of the epidemic. Also, it is fair to state that almost everything that was done during the epidemic might be repeated without a single change in a similar situation. The organization of metropolitan health councils, we feel, is invaluable to public health administration. Only in this way can uniform information be gathered and uniform regulations be initiated in the handling of public health problems extending beyond local jurisdiction.

#### ABSTRACT OF DISCUSSION

ON PAPERS OF DR. NEAL, DRS. LEAKE, MUSSON AND CHOPE,  
DRS. MUCKENFUSS, ARMSTRONG AND WEBSTER, DR.  
HEMPELMANN, DRS. MCCORDOCK, COLLIER AND  
GRAY, DR. JONES, DR. ESCHENBRENNER  
AND DRS. BREDECK AND ZENTAI

DR. W. E. CONKLIN, Paris, Ill. In August 1932 a disease of unusual and vicious character suddenly attacked some thirty people in Paris, Ill. After several conferences and consultations a diagnosis of epidemic encephalitis was made, based on the following symptoms and signs. The first symptom to appear was headache, which rapidly became more severe and was accompanied by nausea and vomiting, which was projectile in character. The temperature rose rapidly in the first twenty-four hours to 104 and 105 F. The pulse was out of all proportion to the temperature and remained between 80 and 100, the respiratory rate was also correspondingly slow, being about normal. All these occurred in the first twenty-four hours of the disease. The patients then passed into a semiconscious state, during which they were restless, picked at the bedclothes and at times required restraint. The more seriously ill patients became irrational and delirious. At no time in this semiconscious state could the patient answer questions. The less severely ill patients could reply with difficulty. These persons complained of severe headache and nausea and desired to lie in a darkened room. They also complained of double vision. This phase was followed by delirium, coma and death or recovery. The time elapsed from the onset of the disease to delirium was from twenty-four to forty-eight hours. During this stuporous state the patients also suffered from involuntary movements. The face had a masklike expression and the eyes were fixed. On moving the head the patient complained of pain. The neck was rigid and painful to the touch. The tongue showed a fine tremor but no deviation. The throat was injected but there was no complaint of soreness, cough or coryza. There was a hypertonicity of all the muscles, and extreme irritability to any kind of stimulation. The urine and the blood count showed nothing abnormal. The spinal fluid was clear and under increased pressure. The prognosis varied with the stage of the disease and the age of the individual. Those who passed from delirium into coma did not recover. These persons were invariably over 60 years of age. Younger persons seemed to have a better reaction to the disease, and the tendency to recovery was marked. The condition was confined to the higher age groups. There were no two cases in the same household. It appeared in all walks of life, there being no evident environmental factor. Treatment was entirely symptomatic. Isolation

was the only possible prophylaxis. The course of the disease was stormy. The active symptoms terminated in death in a week or recovery began. Recovery was gradual and progressive, there being no instance of relapse or recurrence, and no sequelae. There was no evidence of contagion.

DR FRANK R. FINNIGAN, St. Louis. Dr. E. C. Rosenow studied the encephalitis epidemic at the DePaul Hospital in St. Louis in the early fall of 1933. He had prepared an antistreptococcus serum from previous sporadic cases of encephalitis throughout the country, and this serum was administered to some of the patients at the hospital. There were thirty-five severe cases of epidemic encephalitis admitted to the DePaul Hospital during the epidemic of 1933. Treatment other than the serum was chiefly symptomatic. The cases in which the serum was administered were not selected. The total number of cases was thirty-five. Fifteen patients received serum and twenty did not. Of the fifteen patients who received the serum, two died and thirteen recovered, making a mortality rate of 13.3 per cent. Of the patients who did not receive the serum, seven died and thirteen recovered, making a mortality rate of 35 per cent. The average age of those who died in the group treated with serum was 65. The average age of those who died in the group not treated with serum was 64. The ages of those who recovered in both groups was approximately the same. They all exhibited a slight to moderate leukocytosis with a slight shift to the left. They all had an increased spinal fluid cell count, globulin and sugar. The differential count of the fluid showed a preponderance of lymphocytes in the majority of cases. I do not feel that the spinal fluid cell count was of any prognostic aid. In a group of twelve cases of post-encephalitic headache and neuritis in which no serum was given, striking results were obtained by the use of the antistreptococcus vaccine and serum. These figures support the clinical impression that the specific treatment is of value.

DR J. W. ESCHENBRENNER, St. Louis. Three cases were treated with Rosenow's serum. Two patients received 5 cc twice and one received 5 cc once. The last mentioned patient, receiving only 5 cc, was transferred to another hospital and died later. I think that one of the patients receiving 5 cc twice also died.

DR. RALPH S. MUCKENFUSS, St. Louis. I wish to add a few statements regarding the antistreptococcus serum of Dr. Rosenow. I object to calling the antistreptococcus serum specific. A number of strains of streptococci isolated by Dr. Rosenow from encephalitis patients and considered by him capable of reproducing the typical disease in rabbits were studied in Dr. Bronfenbrenner's laboratory. The only lesion caused in experimental animals by these strains was meningitis. This was obvious on microscopic examination but not grossly. In addition, serum of convalescents known to have neutralizing antibodies for the virus had no influence whatever on the activity of these streptococci.

DR. PAUL J. ZENTAY, St. Louis. As secretary of the Metropolitan Health Council and ex-officio secretary of the follow-up committee, I can qualify some of these statements. We handled the follow-up of almost 840 cases. Anybody who tries to follow up a large number of cases of any type knows what difficulties one encounters in evaluating the reports. The follow-up was organized in such a manner that all the cases treated in the hospitals were reexamined at the same place and by the same physicians who observed the cases during the illness. In many instances in which private physicians took care of the patients during the acute illness, we had to refrain from examination of the patient and resort to the questionnaire method. Sending questionnaires to doctors and getting replies naturally involves many errors, and as we try to interpret these questionnaires we have found that many of the doctors misunderstood our questions and replied in the sense of what they found during the acute illness and not at the time of reexamination. It is planned to have another reexamination in the next few months and still another before the end of the year, and two more the following year. In this way we may be able to say something more reliable about prognosis. So far as the publications are concerned, in the monograph which is in the press now a part of the chapter on etiology is devoted to the experiments with streptococci. Any one interested in the

results of those experiments can read there just what they are worth. The statement that no publicity was given to the streptococcus theory is incorrect. The St. Louis newspapers were practically flooded with publicity on that phase of the problem.

## Clinical Notes, Suggestions and New Instruments

### CHOLECYSTITIS AND CHOLELITHIASIS OF CHILDHOOD

HOWARD B. HAMILTON, M.D., C. O. RICH, M.D., AND  
J. DEWEY BIGGARD, M.D., OMAHA

A case report of cholecystitis with cholelithiasis in a boy, aged 8 years, is here recorded to stress the necessity of consideration of lesions of the gallbladder in the differential diagnosis of abdominal disease in children. It is probable that pathologic changes in the preadolescent gallbladder are not as rare as clinical and postmortem records indicate. For this reason and for the reason that many of these cases present long and indefinite antecedent histories, we believe that children who have indefinite abdominal symptoms of epigastric pain and indigestion should be investigated more frequently with such diagnostic aids as cholecystography.

In 1928 Potter<sup>1</sup> reported four personal cases of gallbladder disease in children 4½, 6, 11 and 15 years of age, and he supplemented the report with a review of the literature. He was able to collect 226 cases in which the ages were less than 15 years, as follows: fetuses 2, new-born infants 12, 1 day old 9, infants 19, less than 1 year 18, between 1 and 5 years 26, between 5 and 10 years 55, and between 10 and 15 years 85. Other interesting facts were gleaned from this analysis. In relation to sex the division was males 62, females 74, not stated 90. Cholecystitis was associated with stones in 44, without stones in 59, with jaundice in 30, and not stated in 93 cases. Stones were present in 140, absent in 48, and not stated in 128 cases. Primary malignant neoplasms occurred in 2 cases. Jaundice was present in 64, absent in 34, and not stated in 128 cases.

#### REPORT OF CASE

A. A., a boy, aged 8 years, was admitted to the University Hospital, April 5, 1934, and related that he had been perfectly well until six days previously, when he was seized suddenly with moderately severe cramplike pain in the epigastrium. The pain was partially relieved two hours later when he vomited several times. The vomitus contained bile and some undigested food.

Twelve hours after onset, the pain shifted to an area immediately to the right of the umbilicus. No relief was obtained from ingestion of soda or from three enemas.

Twenty-four hours after the onset the pain subsided, but soreness just to the right of the umbilicus and nausea persisted until admission. Despite constant nausea, dizziness, occasional twitches of pain and weakness, he attended school for three days.

Four hours before admission he was again suddenly seized with severe pain just to the right of the umbilicus, and he vomited several times. The vomitus contained some food but no blood or coffee grounds. The pain persisted without relief.

From his second year of life to the present he had complained periodically of attacks of pain in the epigastrium and right hypochondrium associated with nausea and gaseous eructations but never with vomiting. He had never complained of pain in the back, nor had there been jaundice, clay-colored stools, or evidence of bile in the urine. With recent attacks there had frequently been an elevation of temperature to 102 F but no chills.

The family and past histories were essentially negative and there was no history of familial jaundice or gallbladder disease.

The boy was well developed and well nourished but not obese. His cheeks were slightly flushed and he was more comfortable

From the Department of Pediatrics and Surgery, University of Nebraska College of Medicine.  
1. Potter, A. H. Gallbladder Disease in Young Subjects. Surg., Gynec. & Obst. 46: 795 (June) 1928.

with the right thigh flexed. Both sclerae were slightly injected but were not icteric. The tonsils were large and infected. The lungs were clear and the heart was normal in size and had normal rhythm and no murmurs.

The abdomen was distended moderately and diffusely and there was considerable spasm of all the muscles of the right half of the abdomen, with boardlike rigidity of the right side above the umbilicus. Immediately to the right of the umbilicus, palpation elicited very acute tenderness, and from this point to the costal margin, moderately acute tenderness. There was moderate tenderness in the right lower quadrant. Pressure in both lower quadrants and hyperextension of the thigh caused pain in the region of the umbilicus. There was no tenderness in the flanks, no palpable masses, and no shifting dullness or fluid wave. There was hyperesthesia of the skin of the entire right upper quadrant. Rectal examination elicited no additional information. The extremities and reflexes were normal.

On admission the blood pressure was 95 systolic, 66 diastolic, the temperature 102 by rectum, the pulse 120 and the respiration 24.

The urine was entirely normal and contained no bile. The blood was as follows: hemoglobin 90 per cent, red blood cells 4,690,000, white blood cells 19,400, with segmented polymorphonuclears 55 per cent, staff cells 15, young cells 2, lymphocytes 23 and mononuclears 5.

With an indefinite diagnosis in which was considered acute inflammation of a high appendix, acute cholecystitis and perforated peptic ulcer, operation was performed by one of us

Gallbladder and the solitary stone that it contained in a boy aged 8 years. Note the thick densely fibrotic wall.

(J D B) immediately after admission. Under ether anesthesia the abdomen was opened through a high right rectus incision and was found to contain a moderate amount of clear, free fluid. An enlarged liver showing evidence of hepatitis presented into the wound, with its lower margin on a level with the umbilicus. A markedly thick-walled, injected and slightly edematous gallbladder was freed from the omentum and duodenum, by which it was almost completely concealed and to which it was adherent by both recent delicate and old very dense adhesions. So firm were the adhesions between the gallbladder and the duodenum that cleavage could be accomplished with safety only by peeling the gallbladder serosa off and leaving it attached to the duodenum. There were several enlarged lymph nodes in the hepaticogastroduodenal peritoneal fold. The common and hepatic ducts were not dilated but their walls were thickened. Palpation elicited no evidence of stones in the ducts. The gallbladder was aspirated of 10 cc of thick black bile containing no pus and was then removed from the bottom upward.

The appendix appeared to be normal in appearance except for mild injection. On account of the acute inflammation of the biliary tract, it was decided to defer its removal until later.

A cigaret wick was placed in the right kidney fossa and the wound was closed in layers about it.

The gallbladder wall measured between 4 and 5 mm in thickness and was densely fibrotic and somewhat edematous. The vessels on the surface were widely dilated. The mucosa was markedly injected and presented small focal areas of necrosis. It contained one stone composed of bile salts. The gallbladder and stone are depicted in the accompanying illustration.

The patient's convalescence was uneventful. Twelve days after the cholecystectomy the appendix was removed through a McBurney incision and he was discharged from the hospital five days later. Two months after discharge, he reported that he was feeling perfectly well.

1436 Medical Arts Building

## COARCTATION OF THE AORTA

WILMOT F. PIERCE, M.D. CHICAGO

Death from coarctation of the aorta occurs sometimes from rupture of a mycotic aneurysm in the aortic wall. Hamilton and Abbott<sup>1</sup> mention four such deaths in 200 persons with coarctated aorta, and Evans<sup>2</sup> mentions two in twenty-eight. In the case reported here the aorta also broke, but it was involved from without by suppurative mediastinitis. Part of the abscess wall was formed by the aorta and esophagus.

### REPORT OF CASE

**Clinical History**—B. P., an Italian laborer, aged 35, a patient of Dr. F. H. Straus, was admitted to the Presbyterian Hospital on three occasions. The first was Sept. 26, 1927, when he came in with bronchopneumonia. He had worked in coal mines at hard manual labor for many years and there had never been any symptoms referable to the cardiovascular system. Physical examination revealed, besides the bronchopneumonia, an enlarged heart, palpable and visible pulsations in both suprascapular regions and, over the carotid and subclavian arteries, rough systolic murmurs in both suprascapular regions and lateral to the vertebral column on both sides at the level of the seventh cervical vertebra. The blood pressure was 136 systolic, 86 diastolic, the blood Wassermann reaction was negative. The pneumonia and enlarged heart were confirmed roentgenoscopically. Subsequent blood pressure readings with the patient recumbent were right arm, 144/70, left arm, 148/66. Nothing significant was discovered by other laboratory examinations. It was thought at this time that the blood pressure was temporarily lowered in the midst of an influenza-like infection and that the pulsations in the upper part of the body were due to a large heart and lowered peripheral tonus. The patient was discharged as cured, October 9, thirteen days after his admission.

He returned to work in the coal mines, but two months after his discharge from the hospital he began to experience pain in the upper right abdominal quadrant and dyspnea on exertion. In September 1928 the dyspnea became more marked, and there was edema of both legs and cyanosis of the mucous membranes. These symptoms increased in severity and on November 4, thirteen months after being discharged from the hospital, he was readmitted. This time he was found to have an empyema of the right pleural cavity, edema of the lower extremities, sacrum and genitalia, an enlarged liver and an enlarged heart. Myocardial damage and abnormally dominant action of the left ventricle were displayed in the electrocardiogram. The blood pressure on admission was 140 systolic, 100 diastolic, and subsequently, November 28, it was 142/60 in the right arm and 160/60 in the left. The arteries in the left axillary space and posteriorly just below the scapulae were much enlarged and tortuous, standing out like whipcords. The pulsations and murmurs in the suprascapular regions were not so marked as on the previous admission. The femoral pulses scarcely could be made out. Dr. J. B. Herrick in consultation diagnosed coarctation of the aorta because of the strong and plainly visible character of the pulses in the upper part of the body and the diminution of the femoral pulses.

After the chest had been aspirated several times, drainage of the empyema by the open method was established by Dr. Arthur Dean Bevan. The patient left the hospital, Feb. 28, 1929, with marked improvement in the pulmonary condition.

October 30, just about one year after his second admission, the patient was readmitted because of precordial distress noted particularly after exertion, and hematemesis. The latter had occurred on three different occasions. He was acutely ill, dyspneic, anemic and restless. Marked carotid pulsations were

From the Presbyterian Hospital and the Norman Bridge Laboratory of Pathology, Rush Medical College.

2 Evans, William. *Quart J Med* 2:1 (Jan) 1933.

noted. The heart rhythm was absolutely irregular. The hemoglobin was 36 per cent of normal, red blood cells numbered 1,680,000 per cubic millimeter, and there was blood in the stools. In the electrocardiogram, auriculoventricular conduction was prolonged to 0.22 second, there was left axis deviation, simple tachycardia, left ventricle and right ventricle extrasystoles, and auricular hypertrophy. A roentgenogram of the chest showed the heart markedly enlarged in the region of the left ventricle, infiltration of the lower right lobe with interlobar pleurisy at the level of the fourth rib anteriorly, thickened pleura, and adhesions to the diaphragm. A gastro-intestinal series of roentgenograms was reported negative.

November 5 he vomited 500 cc of bright red blood. November 13 there was another severe similar hemorrhage, and on November 14 he died six hours after a third hematemesis.

**Autopsy** (Dr C. A. Apfelbach).—The body weighed 125 pounds (56.7 Kg). The left side of the thorax was more prominent than the right, and a line drawn through the middle of the sternum curved to the left. A scar, 4 cm long, was present below the lower border of the right scapula. The teeth at their junction with the gums were covered with clotted blood.

*Circumferences of the Mouths of Arteries Forming the Collateral System*

	Right	Left
Innominate	6.0 cm	
Common carotid	3.0 cm	2.5 cm
Subclavian	3.0 cm	5.0 cm
Internal mammary	0.9 cm	2.0 cm
Costocervical trunk	0.5 cm	0.8 cm
Thyrocervical trunk	0.8 cm	1.0 cm
First intercostal	1.2 cm	1.2 cm
Second intercostal	1.0 cm	1.0 cm
Third intercostal	1.0 cm	1.0 cm
Esophageal	0.5 cm	0.5 cm

The abdominal cavity was small, measuring 24 cm from the superior border of the symphysis pubis to the tip of the xiphoid process, whereas the length of the thorax from the root of the neck to the tip of the xiphoid process was 24.5 cm. The left lung was free. Fibrous adhesions, especially firm close to the spine, obliterated the right pleural cavity. The stomach contained foul smelling, dark purple-brown fluid and clotted blood.

The aorta, 18.2 cm beyond its cusps, was constricted. There was no remnant of a ductus arteriosus. The lumen of the aorta at the constriction ended in a pouch directed downward and to the right. The wall of the aorta thickened gradually from the junction of the arch and thoracic portions to a maximum width at the point of occlusion of 4 mm. The septum at the apex of the pouch was less than 1 mm thick and was soft and gray-green. Immediately distal to the coarctation, the aorta was bound firmly to a gray-red and gray-green abscess 6 cm in diameter, adherent to the bodies of the fourth and fifth vertebrae, the posterior wall of the aorta, the esophagus, and the trachea at its bifurcation. A portion of the right posterior wall of the aorta was torn in freeing the abscess from the vertebrae, and a gray-green, soft walled cavity containing purulent fluid and a friable blood clot was opened. The wall of the aorta where it formed the posterior wall of the cavity, a region 3.5 cm in diameter was soft, friable, gray-green and adherent to the blood clot contained within the cavity. Many gray-red thrombi, from 1 to 2 mm in diameter, were adherent to the inner surface of the aorta in this region. The esophagus formed a portion of the wall of the cavity 1.5 cm in diameter and its wall was soft, friable, gray-green and adherent to the blood clot. The lymph nodes in this region were heavily loaded with black pigment and a purulent fluid appeared at once on surfaces made by cutting.

The circumference of the root of the aorta was 9 cm, its wall 2 mm thick. Eight centimeters distal to the attachment of the cusps, the ascending aorta was 7 cm in circumference, the transverse portion averaged 9.5 cm. The circumferences of the mouths of the arteries forming the collateral system are shown in the accompanying table. The inner surfaces of the larger arteries were altered by slightly elevated gray-yellow to bright yellow plaques some of which were calcified.

Distal to the occlusion the abdominal aorta was 6 cm in circumference, and it narrowed gradually to 3.5 cm at the mouths of the renal arteries and to 2.5 cm at the bifurcation

The heart weighed 610 Gm. There were multiple scars beneath the epicardium and there was a sacculcation at the apex 1 cm in diameter and 1 cm in depth. The cavity of the right ventricle was 10 cm long and the wall varied in thickness from 9 mm at the base to 3 mm at the apex. The endocardium of the left ventricle was dull gray-white and opaque and averaged about 0.5 mm in thickness. There was a bright yellow calcified region 5 mm long and 2 mm wide at the auriculoventricular junction and an elevated, gray-white plaque 9 mm in diameter 2 cm from the junction of the right and posterior aortic cusps. The aortic cusps were less than 1 mm thick, smooth and glistening. There were two fenestrations of the left cusp distal to the line of contact with the right, each about 2 mm in diameter. The left and right cusps were fused along their free margins for 6 mm, the right and posterior cusps for 2 mm. There was a sacculcation of the aorta at the apex of the right sinus of Valsalva 5 mm in diameter and 3 mm deep. The walls of the coronary arteries were slightly thickened and there were yellow plaques from 2 to 3 mm in diameter at their mouths. The thickness of the wall of the left ventricle varied from 2 mm at the base to 2 mm at the apex.

Except for marked coal pigmentation and cirrhosis of the liver, which has been reported elsewhere,<sup>3</sup> and for coal pigmentation of the spleen, there was no change of interest in the remaining organs.

In the microscopic sections, the walls of the aorta and the esophagus were necrotic, and scattered through them were occasional small clumps of bacteria, both cocci and bacilli, and blood pigment.

The anatomic diagnosis was coarctation of the aorta, gangrenous abscess of the mediastinum communicating with the thoracic portion of the aorta and esophagus, marked compensatory dilatation of the innominate, carotid, subclavian, internal mammary, and upper intercostal arteries, hypertrophy of the heart, empyema scars of the right pleural cavity, extreme coal pigmentation of the lungs, tracheobronchial lymph glands, and spleen, coal pigmentation and cirrhosis of the liver, blood in the stomach and small bowel and marked general anemia.

GARGLING AND THROAT IRRIGATION

WILLIAM SNOW MD AND J. E. STERN MD, NEW YORK

It seems that the value of gargles remains an undecided matter in the minds of physicians who have given the subject their attention. For this reason and because of extensive exploitation of gargles by advertisers to the lay public, we undertook objective studies of the comparative value of gargles and throat irrigations.

For these observations, subjects used a thin liquid suspension of barium sulphate while lateral x-ray views of the head and neck were made. The first methods included (1) violent gargling, (2) gentle gargling and (3) tilting the head backward and allowing the suspension to run as far backward as possible without gargling. A study of the films showed that with all these methods the tongue is firmly pressed against the soft palate in such a position that the liquid cannot reach the anterior faucial pillars. Occasionally if the subject interrupted the procedure to take a breath of air a small stream of the mixture leaked backward and then had to be swallowed.

Further observations were made in which gravity irrigations were used with the head and neck flexed. The fluid ran from a container placed 18 inches above the mouth through a length of rubber tubing and a narrow irrigating tip. Study of the films showed that the hypopharynx, oropharynx and nasopharynx were thoroughly irrigated, in fact frequently some of the fluid ran out of the nose. With this method the swallowing reflex was not evoked.

CONCLUSIONS

These observations lead us to believe that gargling is ineffective and should be replaced by the gravity irrigation method. This method has of course been used by a number of able physicians for many years.

## Therapeutics

### THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, MD  
CHICAGO

NOTE—In their elaboration, these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, Dr. Bernard Fantus. The views expressed by various members are incorporated in the final draft prepared for publication. The series of articles will be continued from time to time in these columns.—Ed

#### THERAPY OF THE MYCOSES

##### TINEA VERSICOLOR AND ERYTHRASMA

These dermal mycoses differ from trichophytosis in their noninflammatory character. While tinea versicolor and erythrasma differ from each other in exciting cause and clinical characteristics, their treatment is the same. The latter is somewhat more resistant to treatment than the former.

**Cleansing**—A hot bath is given and rubbing with soap, preferably Lunient or Soft Soap or a laundry soap, and using a nail brush, then drying and applying.

**Parasiticide**—A 5 per cent aqueous solution of sodium thiosulphate is thoroughly applied to the patches by means of a flannel cloth. This is followed by a 3 per cent aqueous solution of tartaric acid, also vigorously rubbed in with a flannel cloth. In this manner nascent sulphur and sulphurous acid are produced. The treatment employed nightly for one week usually brings about a cure, provided fresh underclothing is applied and care is taken to disinfect the infected underclothing thoroughly, as by boiling. These measures are required to prevent recurrence.

##### TRICHOPHYTOSIS (RINGWORM)

The diagnosis is generally suggested by the characteristic appearance of the lesions and may be made certain by microscopic examination of scrapings or of hair placed on a slide with a few drops of 15 per cent solution of sodium hydroxide on which a cover glass is pressed firmly. The Giemsa stain brings out the details.

Owing to fundamental difference in technique, the therapy of trichophytosis is discussed under three headings: ringworm of the nonhairy parts, ringworm of the hairy parts, and ringworm of the nails.

**Ringworm of the Nonhairy Parts**—Prophylaxis. Foot coverings should be constantly worn when the feet are liable to be exposed to contact with infected moist places, such as those around swimming pools. Sodium thiosulphate 10 per cent solution or, better, a powder

##### PRESCRIPTION 1—Thiosulphate Dusting Powder

Rx	Sodium thiosulphate	6.00 Gm
	Boric acid	24.00 Gm
M	Label	Dusting powder (prophylactic)

containing 20 per cent of sodium thiosulphate in boric acid (prescription 1), should be applied to the feet and footwear after bathing, or morning and evening. Shoes may be disinfected by placing in them a piece of blotting paper on which a teaspoonful of Solution of Formaldehyde is poured. They are kept wrapped for twenty-four hours and then aired thoroughly. Corrosive Mercuric Chloride solution, 1:1,000 for twenty-four

hours, disinfects clothing, which should be washed before and after the disinfection.

**Treatment** To get rid of the parasites, exfoliation of the affected epidermis is generally required. Agents strong enough to effect this are not tolerated by an acutely inflamed skin. Therefore, when eczematoid dermatitis is present, this must first be treated (see Eczema). Only after the acute inflammation has subsided may remedies be applied that are strong enough to effect a cure. To prevent relapses, which are very liable to occur, the measures listed under "prophylaxis" should be employed. It is especially important to keep the parts dry as much as possible. Hyperhidrosis (qv) may require special treatment.

Washing frequently with soap and water will remove scales, mycelia and spores. Green soap may be used in sluggish cases.

Desquamation is required for disinfection, as the mycelia have invaded the epidermis. This may be induced by the ethyl chloride spray, salicylic acid, silver nitrate, solution of formaldehyde or roentgenotherapy.

The Ethyl Chloride spray may be used to freeze not only the affected area but well beyond the border of the lesion, the tissue being maintained in a frozen condition (snow white) for from one-half to one minute. Prior to the application, loose skin edges or overhanging margins should be trimmed away. When, after a period of from five to seven days, the reactionary phenomena have subsided, the treatment may be repeated, if required.

##### PRESCRIPTION 2—Salicylic Acid Lotion

Rx	Salicylic acid	6.00 Gm
	Alcohol	to make 60.00 cc.
M	Label	Apply locally

It is important that Salicylic Acid, 10 per cent in alcohol (prescription 2), or any other discutient application be made well beyond the visibly affected area, for this usually also lodges parasites.

Silver Nitrate cauterization is utilized for deep fissures.

Solution of Formaldehyde, lightly swabbed on, is so powerful that it should be employed only in lesions of a very sluggish type. Its application may be preceded and followed after two or three minutes by 2.5 per cent Phenol solution, to lessen its painfulness.

Roentgenotherapy is not required in the superficial form. It should be reserved for the keratotic and verrucous types, in which it is administered in large doses preferably, 85 kilovolts, 5 milliamperes, 50 cm. distance and 400 roentgens. This should not be repeated for three weeks. Roentgen therapy must not be employed until all irritation from powerful chemicals has subsided. Only soothing applications, such as Calamine Lotion, are permissible between the applications.

Soothing applications may be employed in the intervals between irritative treatments. Talcum or, if considerable irritation has resulted, Zinc Paste dusted with Talcum.

**Ringworm of the Hairy Parts**—Prophylaxis. Ringworm of the scalp, which occurs almost exclusively in children, should be prevented from affecting other children by isolation of the patient or, at least, by the patient's constantly wearing a close fitting cap. Combs should be burned and toilet articles disinfected by Compound Solution of Cresol diluted to 5 per cent strength. Ringworm of the beard should be prevented by tonsorial asepsis.

Treatment 1 Temporary epilation is an essential preliminary to cure in this obstinate and troublesome affliction

(a) Roentgen epilation occurs from seventeen to twenty-one days after appropriate irradiation and lasts for two or three months. As this treatment is very exacting and should be carried out only by an expert, the technic is not given here. One must wait at least two weeks after irritative applications before undertaking irradiation.

(b) Manual epilation is much more troublesome and painful and requires months or years for cure. Hair in the affected area and around the margin must be pulled out with tweezers and the rest of the hair clipped close or shaved.

(c) Thallium epilation is probably too toxic to be recommended.

Cleansing by a daily shampoo with soap and hot water should be begun after the crusts have been softened with oil or a starch poultice. Liniment of Soft Soap is very effective but probably too irritative to be used daily. After the cleansing, the part is thoroughly dried and parasitocidal ointment or lotion is applied.

In ringworm of the hairy parts, ointments are superior to lotions as the administration form for parasitocides they penetrate better and can be kept in constant contact with the affected area. They are best applied over night. During the day, lotions may be preferred. They should be alcoholic, ethereal or chloroformic rather than aqueous, because the former penetrate the

#### PRESCRIPTION 3—Sulphur Ointment

R Precipitated sulphur 1.50 Gm  
Petrolatum 30.00 Gm  
M and Label Rub in gently once or twice daily. Strength may gradually be increased up to 20 per cent.

#### PRESCRIPTION 4—Compound Benzoic Acid Ointment

R Salicylic acid 1.00 Gm  
Benzoic acid 2.00 Gm  
Ointment of rose water 30.00 Gm  
M and Label Apply locally twice daily. Strength may be doubled if necessary.

Note: The effect of this should be compared with that of a 10 per cent ointment of either of the ingredients to determine whether there lies any special virtue in this particular combination which may well be doubted.

#### PRESCRIPTION 5—Chrysarobin Ointment

R Chrysarobin 1.50 Gm  
Petrolatum 30.00 Gm  
M and Label Apply with care against getting it in the eyes.

#### PRESCRIPTION 6—Salicylic Acid Pigment

R Salicylic acid 1.50 Gm  
Chloroform 30.00 cc  
M and Label Paint on affected area twice daily until desquamation occurs.

hair follicles more readily. Success probably depends more on thoroughness, perseverance and intelligence of application than on the particular germicide selected.

For ointments, one may choose Iodine Ointment (U S P), sulphur ointment (prescription 3), or compound benzoic acid (Whitfield's) ointment (prescription 4) and in obstinate cases chrysarobin ointment (prescription 5). The latter must be employed with care against getting it in the eyes. In the case of Whitfield's ointment it may well be asked whether 10 per cent of either salicylic acid or benzoic acid might not be as good, and this question should be settled by clinical study, as the first law of rational combining in prescriptions postulates that the reason for the presence of each and every ingredient in a prescription must be definitely understood.

As a lotion, Tincture of Iodine in full strength or diluted may be painted on once or twice daily. Or else chloroformic solution of salicylic acid (prescription 6) may be painted on until desquamation occurs.

*Ringworm of the Nails*—This localization is of importance, because it may act as a focus of infection for other portions of the body or other persons.

The nail should be removed as far as possible by trimming off as much as one can without pain by means of knife or scissors, softening the remainder with Solu-

#### PRESCRIPTION 7—Corrosive Sublimate Lotion

R Corrosive mercuric chloride 0.06 Gm  
Alcohol 30.00 Gm  
M and Label Apply after softening nail.

tion of Potassium Hydroxide and scraping it thin with a knife blade or a piece of glass. In obstinate cases, surgical removal of the nail (preferably under gas-oxygen anesthesia) is necessary.

The affected area should be soaked twice daily with alcoholic solution of mercuric chloride (prescription 7) and dried, and Ointment of Ammoniated Mercury (half to full strength) and a protective dressing applied.

#### BLASTOMYCOSIS, SPOROTRICHOSIS AND ACTINOMYCOSIS

*Diagnosis*—The possibility of these mycoses should always be borne in mind in chronic, torpid infectious granulomas simulating tuberculosis, syphilis, sarcoma or carcinoma but with a tendency to suppurative degeneration and fistula formation. Subjective symptoms are remarkably slight, excepting such as are caused by secondary pus infection. These three diseases are dealt with here under one heading, as the therapy of these conditions is very similar. In all three of these, the infection may be confined to the skin, which is the most common localization of blastomycosis. It may invade the subcutaneous tissue, which is the usual localization of sporotrichosis, or it may involve the deeper tissues of the body, an invasion that occurs most commonly in actinomycosis, which generally affects the head and neck but may attack the abdominal or the thoracic organs, while primary cutaneous actinomycosis is rare. Pulmonary as well as systemic dissemination of blastomycosis or of sporotrichosis is rare, fortunately, as it is nearly always fatal.

Blastomycosis is suggested by patches of papulopustules with elevated violaceous borders in which there are numerous abscesses.

Sporotrichosis is characterized by subcutaneous painless nodules, which slowly enlarge, soften and form cold abscesses and ultimately fistulas, with the possibility of metastatic involvement elsewhere, usually in the form of an ascending lymphangitis.

Actinomycosis should be suspected when there is an indurated swelling in the cervicofacial region, when so-called sulphur granules are noted in the pus, or when a patient suffers from an apparently incurable, chronically draining postappendectomy or other abdominal sinus, also when there is rib destruction with what appears to be a lung abscess.

The finding on microscopic or culture examination of the characteristic fungus in the pus clinches the diagnosis in all these mycoses.

*Prophylaxis*—Chewing of straw, weeds or grain must be avoided, as actinomycosis may be contracted thereby.

*Treatment*—Iodides in massive doses daily for a long time are the sheet anchor of treatment in these mycoses. From 6 to 12 Gm daily is usually employed. The Solu-

tion of Potassium Iodide, N F (saturated solution), may conveniently be used, starting with 1 cc in a glassful of milk three times daily after meals and gradually increasing the dosage until the limit of tolerance is reached as indicated by coryza, anorexia, digestive disturbance, the phenomena of hyperthyroidism or the development of cachexia. The treatment should continue for at least one month after apparent cure, with immediate readministration at indication of relapse.

Roentgen irradiation may be used in a dosage of 140 kilovolts, with 0.25 mm of copper and 1 mm of aluminum filtration for relatively superficial lesions to 0.5 mm

#### PRESCRIPTION 8—Iodine Solution

R	Iodine	1.00 Gm
	Potassium iodide	10.00 Gm
	Distilled water	500.00 cc

M and Label Use on gauze as moist dressing

of copper and 1 mm of aluminum for deep involvement. A sufficient number of portals should be used to secure 300 roentgens at the site of the lesion. Such treatment may be repeated every two weeks for at least six months.

Surgical intervention should be confined to the evacuation of pus, excepting only in cases in which complete extirpation of the lesion is possible. Curettage should be avoided, as it may lead to dissemination of infection. Indeed, evacuation of the pus may be accomplished by mere puncture and aspiration, and the cavity filled with a 1 per cent solution of sodium iodide. Ulcerated lesions may be painted with Tincture of Iodine and dressed with an iodide solution, 1:500 (prescription 8).

### RESUSCITATION

YANDELL HENDERSON, PH.D.  
NEW HAVEN, CONN.

(Concluded from page 754)

#### ASPHYXIA NEONATORUM<sup>20</sup>

There is no good reason to look, as many writers have done, for any reactions in the neurorespiratory system of a baby, either before or after birth, essentially different from those of an older child or adult. The normal baby starts to breathe under essentially the same stimulus that causes an adult to breathe again after holding his breath. If in the adult the breath holding has been aided by a preliminary period of voluntarily forced ventilation, the analogy is even closer. The reason that the fetus does not breathe in utero is that its blood is too well arterialized to stimulate the fetal neurorespiratory system, which is rather inexcitable so long as the lungs are atelectatic. If respiratory efforts do occur, the thoracic muscles, which are barely strong enough to dilate the lungs with thin air after birth, fail to draw in more than a minute amount of the much less easily inspired amniotic liquor. If some fluid is drawn in, it is quickly absorbed into the blood, for the lungs are by far the most absorptive organs in the body. The particles of meconium sometimes found in the trachea are probably drawn in from the mouth immediately after birth.

When cold water, or even cold air, is suddenly poured over an adult, the cutaneous stimulus causes him to "catch his breath" in a deep and prolonged or even repeated inspiration. Introduction to a cold world induces the same reaction in a normal baby. Its lungs are thus at least partially expanded. So long as they are atelectatic, the lungs send no impulses over the vagi to the respiratory center. But as soon as the lungs are even partially expanded the vagi carry impulses to the respiratory center that call forth the Hering-Breuer reflexes. These are the reflexes that determine the alternation of inspiration and expiration in normal breathing.

If during birth the head of the child is compressed and deformed, and particularly if an intracranial hemorrhage continues the compression of the respiratory center after birth, the blood supply to the center is diminished. If the umbilical cord is partially compressed, the entire body is correspondingly asphyxiated. A formation of lactic acid occurs, the  $pH$  and alkali of the blood are diminished, and the carbon dioxide content, which at first is increased, is later diminished by escape presumably through the placenta. If these conditions are brief, the baby is livid, if they are prolonged, it is pallid. To whatever extent the sensitivity of the respiratory center has been diminished by lack of oxygen, a stronger stimulus in the form of increased pressure of carbon dioxide is needed to excite the neurorespiratory system to activity. Once its activity is induced, the renewed supply of oxygen gradually restores its normal sensitivity. Thereafter, respiration continues under a merely normal amount of carbon dioxide in the blood.

Atelectasis, however, is not so quickly overcome. Even in wholly normal babies the lungs are not fully expanded for hours, days, or even longer. A continuance of atelectatic areas provides conditions favorable for the development of pulmonary infections. The obvious correction is a routine roentgen examination of every baby a few days after birth, or else some dilating treatment without examination. For this purpose most textbooks still recommend that the baby should be made to cry. A much more effective means of accomplishing this end is afforded by repeated brief inhalations of from 5 to 7 per cent carbon dioxide. Herein lies an immediate possibility of a large decrease of the present high mortality of the first month of life.

#### ANESTHETIC DEPRESSION<sup>20</sup>

Few branches of medicine have made such great advances within the past three decades as has the art of anesthesia. Among these advances, the use of carbon dioxide is preeminent. Every anesthetist now knows that the hyperpnea of the excitement stage of anesthesia decreases the carbon dioxide of the blood and tends to induce failure of breathing under full anesthesia. He knows also that, on the contrary, a moderate amount of rebreathing deepens and steadies respiration. This knowledge and the inhalation of carbon dioxide, when needed, have almost entirely freed surgical anesthesia from what was formerly its continual imminent danger—failure of respiration.

It is not many years since it was a matter of course that after nearly every major operation the patient lay long unconscious, hypopneic and therefore cyanotic, then nauseated and tasting the incompletely exhaled anesthetic for hours. In part these conditions were due to apnea induced by overbreathing and washing

out of carbon dioxide under the influence of anesthetic excitement and moderate oxygen deficiency. In part they were due also to the acarbic—diminished blood alkali—that asphyxia and acapnia induce. Simultaneously the volume of the circulation was subnormal, owing largely to the stagnation of the blood in atonic tissues.<sup>24</sup>

All these features of depression are now largely avoided by the increasing skill of anesthetists in preventing both anoxia and acapnia. But in extreme cases in which such ill effects do still sometimes occur they are rapidly and largely counteracted by means of inhalation of carbon dioxide. Full deep breathing returns, cyanosis disappears, the tonus of the muscles is recovered, the skin becomes pink as its vessels fill with blood from the previously atonic muscles, the jugular and other superficial veins are again distended, bringing a full supply of blood to the right heart, and with this restoration of the venous return, arterial pressure and a full pulse are reestablished.

Within the last few years yet another benefit accruing from the use of carbon dioxide and prevention of acapnia has come to light. Under acapnia and under any diminution of tonus the so-called vital capacity of the lungs is decreased. After nearly all surgical operations, especially those in the abdomen, the atonic diaphragm is relaxed headward by several centimeters. Under this condition the lungs are partially collapsed and some of the airways may be blocked. The air from the occluded parts of the lungs is soon absorbed and an area of atelectasis or even a massive collapse of one lung results. Prevention of the normal drainage of the lung through the airways permits the development of infection, resulting in what was formerly called "post-operative pneumonia." Now the etiology of postoperative pulmonary complications is understood, and the means of its prevention are available in the restoration of the tonus of the respiratory muscles and dilation of the lungs by full deep breathing.<sup>25</sup>

How far similar measures may aid in pneumonia of nonsurgical origin, particularly in bronchial pneumonia in children, is still undetermined. It appears, however, that the prevention of cyanosis by inhalation of oxygen is beneficial in lobar pneumonia in adults and that the patients do at least as well, perhaps better, if the carbon dioxide exhaled is allowed to accumulate up to at least 1 or 2 per cent in the oxygen tent.<sup>26</sup>

#### CARBON MONOXIDE ASPHYXIA<sup>27</sup>

The treatment of carbon monoxide asphyxia is now so effectively performed by the rescue crews of city fire and police departments and of gas and electric companies with their inhalators that the main duty of the physician is not to interfere with the artificial respiration. He should not even make a physical examination that requires cessation of artificial respiration,

during which the patient may die. He should restrain his impulse to administer hypodermic, intravenous or intracardiac medication of any kind. The claims for methylene blue, lobeline and other drugs of similar properties have been completely disproved both in theory and in practice. Respiratory stimulants are generally cardiac depressants. When administered to a patient in profound respiratory depression they often afford an immediate and striking pharmacologic demonstration, but the patient is much the worse for it the next day.

Carbon monoxide forms only a loose and reversible combination with the hemoglobin of the blood. But until it is displaced, and the oxygen carrying power of the blood is restored, the asphyxial effect continues and is cumulative. The differences between asphyxiation by water—that is, drowning—and prolonged asphyxiation by carbon monoxide are important. Once the man who has been in the water is brought back to fairly normal breathing by means of artificial respiration, especially when supplemented by inhalation, complete recovery is almost certain to follow. In carbon monoxide asphyxia it is only for cases of brief and acute exposure that artificial respiration is an important factor in resuscitation. In cases of prolonged exposure inducing acarbic asphyxia it is only by a rare chance that the victim is found in the brief period—less than ten, or even five minutes—between cessation of respiration and fibrillation and standstill of the heart. After that he is irretrievably dead, before that he is still breathing spontaneously when removed from the poisonous atmosphere. Such cases are numerous, and it is for them that the advance in the technic of resuscitation has made its greatest contribution in the saving of life. They do not need and are little helped by artificial respiration, but they do need inhalational treatment, and in the acarbic or pseudo-acidotic cases it is needed even more than in the cases of apnea after short asphyxiation. To be most beneficial the inhalation must be immediate—on the spot, not after removal to the hospital.

In every large hospital a few years ago, before the city rescue crews were supplied with inhalators, cases of carbon monoxide poisoning were frequently seen in which, even hours after the patients were brought in by the ambulance, they were completely comatose. It was supposed at that time that their blood must still be largely combined with carbon monoxide, and for this reason bleeding and transfusion were sometimes done. Spectroscopic examination showed, however, that even without any treatment whatever most of the carbon monoxide was eliminated from the blood within a few hours. This fact demonstrated the uselessness of late transfusion and it demonstrated much more. Such of these patients as later recovered consciousness suffered acute and prolonged headache and nausea. Some suffered mental or physical impairment. In those who died, autopsy revealed asphyxial injuries in the brain. Thus it became evident that the continuance of the coma is not due to continuance of asphyxia but that it is due to the injury to the nervous system that was developed during the asphyxia. It became evident also that measures for the relief of asphyxia, when applied late, can at best be of relatively slight benefit. The primary object to be aimed at in the treatment of all cases of prolonged asphyxia is to apply inhalational

treatment for the rapid elimination of carbon monoxide within the shortest possible time after removal of the patient from the poisonous atmosphere

#### ASPHYXIA FROM MORPHINE, ALCOHOL, AND OTHER RESPIRATORY DEPRESSANTS

One of the principal effects of morphine is to decrease and, in sufficiently large dosage, finally almost to abolish the sensitivity of the neurorespiratory system to its normal stimulus, carbon dioxide. It is the resulting depression and final cessation of respiration that cause death from anoxia in cases of morphine poisoning. It is probable that many deaths among the newborn are due to the administration of morphine to the mother and the diffusion of the drug through the placenta to the child. The treatment of the resulting neonatal asphyxia has already been discussed.

For adults so long as pulmonary ventilation is maintained, either naturally or artificially, life continues and resuscitation results. If the narcosis is not too intense, it may be combated effectively by inhalation of quite high percentages of carbon dioxide with oxygen. For extreme cases artificial respiration by intratracheal insufflation of oxygen or air, interrupted ten or twelve times a minute, will maintain life. Artificial respiration with the Eve-Cornish tilting board will probably also be found effective.

Patients with alcoholic coma<sup>28</sup> also are rapidly revived and sobered under the increased respiration induced by inhalation of carbon dioxide. It would save trouble and expense if this treatment for alcoholic intoxication was utilized by the police.

#### CYANIDE ASPHYXIA

Cyanide is now extensively used for the fumigation of buildings, ships, greenhouses and even trees. The canister gas mask affords effective protection against inhalation. Yet moderate degrees of poisoning are fairly frequent, and severe or even fatal cases occur often enough to be important.

The action of cyanide in the body is to induce asphyxia by inhibiting the respiratory ferment in the cells of the tissues. As the poison is extremely volatile, it is not only rapidly absorbed but may also be equally rapidly eliminated through the lungs. The treatment of slight cases, as recommended by Dr. C. L. Williams<sup>29</sup> of the U. S. Quarantine Station at New York, is therefore "fresh air and plenty of it." In cases that have progressed to apnea, artificial respiration should also be immediately applied. As cyanide is a powerful respiratory stimulant, the victim, during the asphyxiation, will have developed some degree of acapnia. To counteract this condition and hasten elimination of the poison, carbon dioxide diluted in air or in oxygen should be given by inhalation.

Treatment by intravenous infusion has some advocates. It is based on the fact that methemoglobin combines with cyanide. The substances injected are therefore such drugs as are known to convert hemoglobin into methemoglobin. Hug<sup>30</sup> advocates alternating

injections of sodium nitrite and sodium thiosulphate. It seems to me, however, that, especially when the poison has been absorbed through the lungs, it is better to promote elimination by active pulmonary ventilation than to attempt to fix it in a combination in the blood.

In adopting measures of resuscitation, it is important to choose those that themselves involve no subsequent ill effects.

#### PULMONARY EDEMA FROM IRRITANT GASES<sup>31</sup>

The edema of the lungs induced by irritant gases results in asphyxia. It is chiefly a problem of war. But in the industries of peace also many cases occur in which the victims have inhaled ammonia, sulphur dioxide, chlorine, the fumes of various acids, phosgene, or the oxides of nitrogen. The irritant effects of the first four manifest themselves immediately and thus give warning for escape. Phosgene, on the contrary, and especially the oxides of nitrogen, whether from the spilling of nitric acid on wood, from the fumes of explosives, or from burning celluloid, are of less immediate choking character but are of much more serious subsequent effect. Hours after exposure to these gases pulmonary edema may develop, and the victim may drown slowly in the fluid exuding into his lungs.

For the prevention and treatment of pulmonary edema after inhalation of any irritant gas, the first essential is absolute rest for from twenty-four to forty-eight hours. The patient, even though in no apparent danger of developing edema, should be kept in bed, and if any indications of edema have appeared, he should on no account be allowed even to sit up in bed. If asked to sit up for auscultation, he may do so and an instant later fall back dead.

The asphyxia from pulmonary edema may take either of two forms, or one may follow the other: a gray and shocklike form, and a cyanotic form with extreme venous congestion. The gray state involves deficiency of oxygen in the blood without retention of carbon dioxide, or there may even be some degree of acapnia. The congested state develops when the lungs are waterlogged to such a degree that not only oxygen cannot pass in but also the much more easily diffusible carbon dioxide cannot pass out. The resulting hypercapnia and the obstruction to the flow of blood through the lungs are the joint causes of the venous congestion and overloaded heart.

For both conditions oxygen should be administered continuously in a concentration sufficient, if possible, to overcome cyanosis. Carbon dioxide inhalation tends to revive the patient from the stuporous condition induced by asphyxia, but it does not prevent the further development of asphyxia. It may even increase the venous congestion and should therefore not be administered in the stage of venous congestion.

The venous congestion may be treated by bleeding, after which intravenous infusion of saline solution has been recommended.<sup>32</sup> But the chief point to be aimed at is absolute quiescence, for any severe degree of

pulmonary edema generally results fatally in spite of any treatment

Surgeons, who during war become accustomed to seeing huge physical injuries, are shocked by the appearance of patients gasping in pulmonary edema. Yet in fact such patients are so far anesthetized by asphyxia that they actually suffer far less than those with severe gunshot wounds

#### HEMORRHAGE AS A FORM OF ASPHYXIA<sup>33</sup>

Hemorrhage produces its ill effects largely through asphyxia. This is tacitly recognized by surgeons in their preference for transfusion of blood over any mere infusion of a saline or gum solution. The victim of acute exsanguination exhibits air hunger. In less extreme cases the volume of breathing increases with the loss of blood in a manner closely similar to the progressively developing hyperpnea in a man or animal undergoing carbon monoxide asphyxia.

All these facts point to the loss of the red corpuscles as an important feature of hemorrhage. The effect is essentially like the abolition of the oxygen carrying power of the corpuscles by carbon monoxide. This statement does not deny that the diminution of blood volume also impairs the circulation. But simple decrease of blood volume, such as is induced by the diarrhea of cholera, is effectively combated by intravenous infusion of saline solution. Hemorrhage, on the contrary, is only partially and temporarily relieved by restoration of blood volume. For effective relief and the return of normal quiet breathing, restoration of the oxygen carrying power of the blood by restoration of the supply of hemoglobin containing corpuscles is essential.

If, then, hemorrhage is largely a form of asphyxia, the obvious first aid measure is to administer oxygen and to maintain this inhalation by means of an inhalator, a tent, a metabolism apparatus or an anesthesia apparatus supplying oxygen, until transfusion can be performed. Patients with hemorrhage, if left for even a short time without oxygen inhalation or transfusion, develop acarbica. But until the oxygen carrying power of the blood is restored, carbon dioxide is probably best not used. Exsanguinated animals were found by Henderson and Haggard<sup>34</sup> to react badly to inhalation of carbon dioxide. The exsanguinated man or animal cannot overcome even a pseudo-acidosis—that is, acarbica—without restoration of the red corpuscles. Carbon dioxide may prolong life but it cannot recall a normal amount of alkali to the blood except in the presence of an ample supply of oxygen to the tissues.

The main point to be emphasized is this. After a severe hemorrhage it is not enough to stop the loss of blood and to prepare for a transfusion. Until the transfusion can be performed, and even thereafter, oxygen should be continuously administered. Hemorrhagic asphyxia should not be allowed to continue for a minute longer than can possibly be avoided. In all forms of asphyxia, measures of resuscitation, in order to be most effective, must be immediate.

#### FAILURE OF THE CIRCULATION AS A CAUSE OF ASPHYXIA

Surgical and traumatic shock has long been recognized as involving depression and finally failure of the

circulation. A condition results similar in appearance to that induced by hemorrhage, involving a deficient supply of oxygen to the tissues and the usual consequences of such deficiency: acapnia, acarbica and pseudo-acidosis.

In shock without hemorrhage there is, however, no loss of red corpuscles from the body, and the blood alkali is merely displaced. Both corpuscles and alkali may be recalled into use.<sup>34</sup> To effect such recall, both the asphyxia and the acarbica may be combated with inhalation of carbon dioxide and oxygen.

One of the oldest and also the latest of many conceptions of the underlying cause of the depression of the circulation in shock<sup>34</sup> and in illness is that the tonus of all the muscles of the body, both skeletal and visceral, is depressed, and that the blood stagnates in the atonic tissues. Stimulation of respiration with carbon dioxide increases the effective difference of pressure between the tissues of the body and the thorax and thus promotes the venous return to the heart.

In the large majority of all deaths, whatever the initial cause, the sequence is that of increasing weakness, decreasing tonus and failing circulation. The terminal gasps and "death rattle" express the final reaction of the neurorespiratory system to asphyxia.

#### SUMMARY

The conditions to which resuscitation applies are all essentially forms of asphyxia. They include drowning, electric shock, asphyxia of the new-born, carbon monoxide, morphine, cyanide and alcohol poisoning, anesthetic and postoperative depression, pulmonary edema and hemorrhage.

For brief complete asphyxia, involving failure of breathing, the principal measure of resuscitation is artificial respiration, reinforced by inhalation of carbon dioxide and oxygen.

For prolonged asphyxia, inducing coma with depression of breathing, the principal measure of resuscitation is inhalation of carbon dioxide and oxygen, initiated, when needed, by artificial respiration.

The various forms of apparatus for treatment of asphyxia are here evaluated. Artificial respiration apparatus of the laboratory type should be available in the operating room. But such apparatus is not suitable for general use by laymen. Outside the operating room and the hospital, reliance should be placed on inhalators and the Schafer prone pressure method of artificial respiration.

The theory of asphyxia now generally accepted in the medical sciences is inconsistent with the facts of resuscitation established clinically. If the condition now called "acidosis" were really acid poisoning, inhalation of carbon dioxide would further poison the victims of asphyxia. The fact is, on the contrary, that carbon dioxide combined with a supply of oxygen has proved to be the specific cure for asphyxial "acidosis." For further progress in resuscitation and in related problems of clinical physiology the development of a sound theory of asphyxia, and of "acidosis," or acarbica, is urgently needed.

## Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING  
REPORT  
RAYMOND HERTWIG, Secretary

### NOT ACCEPTABLE FONTANA'S MUSHROOM GRAVY

The Fontana Food Products Company of San Francisco submitted to the Committee a product called "Fontana's Mushroom Gravy" prepared from tomato puree, water, olive oil, onions, meat (United States government inspected and passed), white wine, celery, flour, salt, carrots, dried French mushrooms, sugar, parsley, butter, pepper, garlic, rosemary and bay leaf

Analysis (submitted by manufacturer) —	per cent
Moisture	85.1
Ash	2.5
Sodium chloride	2.0
Fat (ether extract)	2.6
Protein (N × 6.25)	2.5
Crude fiber	0.6
Carbohydrates other than crude fiber (by difference)	6.7

**Discussion of Label and Name**—The name "Mushroom Gravy" implies that mushrooms are the principal ingredient, giving the product the food and flavor values of mushrooms, whereas they are present in insignificant quantity only. Food names should truthfully and appropriately identify the nature or ingredients of foods. The label statement "Choice mushrooms, meat, ripe tomatoes, pure olive oil, vegetables and spices" incompletely lists the ingredients and, by giving first place to mushrooms and meat, unduly emphasizes their quantitative importance as components of the product. Descriptive statements of compounded foods should list all ingredients in order of decreasing proportions to be truthful and to properly indicate their relative quantities. Incomplete statements giving first place to ingredients occurring in minor proportion deceive as to the true nature and composition of foods. Illustrations of certain of the ingredients on the label and the omission of others add to the misleading nature of the label. Food manufacturers are obligated to name their products and design their labels so that the public may be truthfully informed in statement and by implication.

The company was advised of the Committee's criticisms of the deceptive name and label but has not demonstrated willingness to make the desired changes. This product, therefore, will not be listed among the Committee's accepted foods.

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary

### JACOB MUSHROOMS BROTH—FANCY BUTTONS—SLICED— SLICED STEMS AND PIECES

**Manufacturer**—Edward H. Jacob, Inc., West Chester, Pa.

**Description**—Hot house mushrooms, respectively broth, buttons, sliced, and sliced stems and pieces.

**Manufacture**—Culture. Mushroom spores obtained by careful collection under sterile conditions from mushrooms of desired color, flavor and texture are used to inoculate a "master jar" containing properly prepared and composted autoclaved manure. Spawn from the master jar is used to inoculate other similarly prepared jars. Specially prepared manure beds (21 C) are planted with the spawn, which rapidly runs through the compost, and after three weeks a one inch layer of dirt is laid over the compost. When the mushroom crop is desired, the bed is watered and the temperature maintained at about 11 C. The mushrooms are picked daily and transferred to the packing plant. The growing season runs from October to June.

**Manure Beds** For preparing the manure beds, manure from urban areas is carefully composted and turned several times until ready for use in the growing beds, which are arranged in two tiers in special mushroom houses without windows and with controlled ventilation. The beds are set to a depth of 8 inches with incompletely decomposed manure. The houses are tightly closed and the ventilation is controlled. The temperature of the compost rises to 54 C and is maintained there for several days. Insects and disease producing organisms are killed and the moisture content adjusts itself to a desired level. When the temperature drops to 21 C the beds are ready for planting with spawn.

**Preparation and Canning** The mushrooms are screened to remove adhering dirt, the stems are cut off at the proper point, and the stems and buttons are separated. The buttons are washed in rapidly circulating water, sorted according to size, inspected (imperfect and blemished pieces are removed), and blanched and shrunk in live steam. The condensed steam constitutes the broth in which the mushrooms are packed. The mushrooms are cooled in water and are drained and packed in tins with the broth, which has been salted and heated to 88 C. The cans are automatically capped, processed for twenty minutes under 15 pounds steam pressure, and cooled.

The mushroom pieces and stems are prepared, canned and processed in the same general manner as the buttons. The sliced mushrooms are automatically sliced.

### NORRIS JUVENILE CANDIES DEXTROSE SPECIAL

**Manufacturer**—Norris Inc., Atlanta, Ga.

**Description**—Confections of various shapes, colors and flavors containing dextrose, corn syrup, flavors (true fruit flavors esters, ethers, lemon, orange and mint oils and United States Department of Agriculture certified food colors).

**Manufacture**—Definite quantities of corn syrup, dextrose and water are heated in a copper steam jacketed vacuum kettle. A "vacuum" of 1½ inches mercury pressure is developed for five minutes, the candy mass is cooled and the flavoring and coloring are worked in. A portion may be pulled. The candy

mass, maintained at a proper temperature, is worked to a desired condition and passed through brass rolls containing molds. The molded candy is cooled, then steamed and rolled in dextrose and packed in boxes. In the case of lollypops, two pieces, one colored and one pulled to milky whiteness, are pulled together, producing a two color piece, which is clipped up by shears and wooden sticks are inserted.

### TORRINGTON CREAMERY IRRADIATED VITAMIN D PASTEURIZED MILKS—HOMOGENIZED AND REGULAR

*Distributor*—Torrington Creamery, Inc., Torrington, Conn.

*Description*—Bottled pasteurized homogenized and regular vitamin D milks irradiated with ultraviolet rays (patent No. 1,680,818).

*Preparation*—The milk complies with legal requirements and is pasteurized by the standard holding method. For description of irradiation, see THE JOURNAL, Oct 7, 1933, page 1155. For the homogenized milk, the milk is homogenized under 1,500 pounds pressure per square inch.

*Vitamins*—Clinical investigation shows these milks to be reliable antirachitic agents if the proper amount is used. Contain 135 U S P X (Revised, 1934) vitamin D units per quart.

*Claims of Distributor*—Irradiated antirachitic pasteurized milks homogenized and regular, having otherwise the flavor and food values of usual pasteurized milk.

### DR P PHILLIPS TREE RIPENED ORANGES, TANGERINES AND GRAPEFRUIT

*Distributor*—Dr P Phillips Company, Orlando, Fla.

*Description*—Fresh, tree-ripened oranges, tangerines and grapefruit passing Florida state standards for maturity, and company standards for appearance and eating quality. No arsenical sprays are used.

*Cultivation and Harvesting*—The fruit is picked from groves owned by the Dr Phillips Company and its affiliates or from groves where similar cultural practices approved by the company are observed. So far as is practicable only uniform fruit, meeting company standards, is packed. Insect and fungus control is obtained by spraying with liquid or dry mixtures of sulphur and lime. Oil-lime sulphur emulsions may be used also. On rare occasions with bad infestations of lemon scab, copper sulphate lime spray is used in the spring but no traces

remain at the time of harvesting. No arsenate of lead or other arsenic sprays are used nor any treatments affecting maturity of the fruit.

Ripe fruit is picked by hand, conveyed to the packing house and inspected on belts by graders, who take out rots and misshapen fruit. The good fruit is immersed in warm soap water to loosen any dirt, sprayed with water while passing over rotating brushes, and dried in racks with warm air. Oranges and grapefruit are polished with dry brushes. The fruit is graded on the basis of appearance into bright, russet and golden grades, stamped with the name of Dr P Phillips, wrapped in paper, packed in boxes by hand, cooled to 2-3 C and shipped to the market.

The Dr Phillips brand fruit must pass maturity and taste tests. Color of the fruit is not a dependable indication of maturity. Picked fruit which does not meet the taste test or which must be artificially colored is packed under other brand names. The Dr Phillips brand is intended to be a tree ripened mature fruit.

*Claims of Distributor*—Only selected properly handled ripe fruit is packed under the trade name "Dr Phillips."

### GOLDEN BEAR CALIFORNIA PURE ORANGE JUICE

*Manufacturer*—Bireley's, Hollywood, Calif.

*Description*—Flash pasteurized California Valencia orange juice retaining in large measure the original vitamin content.

*Manufacture*—Select tree-ripened Valencia oranges are scrubbed in running water, automatically cut in halves and reamed. The juice is strained (avoiding beating in of air), chilled, flash pasteurized by special equipment, automatically canned, sealed and cooled. The equipment is designed to avoid as much as possible incorporation of air in the juice. The time of pasteurizing and canning is less than two minutes.

The trees are not sprayed with arsenic sprays.

Analysis (submitted by manufacturer) —

## THE GASTRO-INTESTINAL TRACT AND THE AUTONOMIC NERVOUS SYSTEM IN POLIOMYELITIS

One of the curious early manifestations of poliomyelitis is the disturbance of the gastro-intestinal tract. In fact, it was proposed long ago that infantile paralysis is primarily an enteric disease<sup>1</sup> and it was suggested that the infective agent might be carried from the intestinal tract to the central nervous system by way of the sympathetic nerves.<sup>2</sup> These theses were generally held to be untenable because repeated efforts to produce the disease by enteral administration of the virus to monkeys failed,<sup>3</sup> with but few exceptions,<sup>4</sup> which, in view of their rarity, were not given serious consideration. It was assumed therefore that ingestion of the virus probably plays no part in the production of poliomyelitis and that the upper respiratory tract, notably the nasal passages, serves as the chief if not the only portal of entry for the infective agent. When, however, as Clark and his associates<sup>5</sup> have shown, the virus is fed to monkeys or injected directly into a loop of intestine, material recovered later from the feces of these animals, or a dialysate of them, may produce typical poliomyelitis when inoculated into other monkeys. No virus could be recovered from the stools of animals suffering from the active disease produced by intracerebral inoculation.

Recently, Toomey at Western Reserve University has published the results of an extensive series of observations and experiments that indicate the necessity for reconsideration of some of the accepted tenets. He found that definite gastro-intestinal involvement occurs as an early sign in a large majority of patients with poliomyelitis (251 out of 386 cases in his series). In

many of these, actual paralysis of the intestine appears to occur, usual measures fail completely to stimulate the bowel.<sup>6</sup> Similarly, disturbances of urinary excretion noted in many patients appear to be referable to transient paralysis of the bladder. Subcutaneous injection into guinea-pigs of fecal emulsions or urine from patients suffering from poliomyelitis caused death in a considerably greater number of animals than did the injection of similar material from normal patients.<sup>6</sup> Lesions observed in the spinal cords of the animals injected with the fecal emulsions from patients with poliomyelitis were strikingly similar to those seen in clinical cases.<sup>7</sup> The previous injection of convalescent serum, but not of normal serum nor of serum obtained during the first few days of the disease, prevented entirely or reduced the severity of the symptoms in the animals.<sup>8</sup> The toxic factor in the stools was readily destroyed by heat and could be removed by filtration. Toomey and von Oettingen<sup>9</sup> have demonstrated that perfusion of the rabbit's intestine in vivo with emulsions of stools from monkeys infected by intracerebral inoculation of poliomyelitis virus, or with the virus itself, produced profound depression of the intestinal musculature so that the latter would not respond even to barium chloride in high concentration, indicating a direct effect on the smooth muscle itself. Incubation of virus with convalescent serum prevented the effect of the enterodepressant factor, but human serum obtained during the acute stages of poliomyelitis or normal monkey serum did not. Whether or not the convalescent serum can neutralize the effect of the enterodepressant fecal factor apparently has not yet been determined. Stools from normal human beings, from the monkeys before they were infected with the virus and from patients with tuberculosis, meningitis, varicella, diphtheria or scarlet fever did not depress the intestine but on the contrary usually stimulated it. Stools from patients with influenza, however, caused definite depression.

Other observations appear further to implicate the intestinal tract in poliomyelitis. The agglutinin titers of the blood serum for organisms of the colon-typhoid group, in patients with the acute disease, were often markedly lower than during convalescence.<sup>10</sup> This was found not to occur in a number of patients suffering from several other acute infectious diseases. As the change in agglutinin titers may have been due either to a diminution from the normal agglutinin level with recovery later or to the development of antibodies to

these organisms de novo, studies were made on monkeys before and after intracerebral inoculation with poliomyelitis virus. It was found that the agglutinin titers dropped sharply in the acute stages of the disease from a previous high level, thus indicating that the former hypothesis is the correct one.

When monkeys are inoculated intracerebrally with poliomyelitis virus, a period of a week or more usually supervenes before paralysis develops. However, virus mixed before injection with combined filtrates of ten day old cultures of organisms of the colon-typhoid group was found to produce hemiparesis in twenty-four hours and quadriplegia in from five to seven days.<sup>11</sup> The filtrates alone did not produce paralysis. On injection of the virus into the lumen of a loop of intestine segregated for a time between two clamps or into the subserosa of the intestine, poliomyelitis regularly supervened. The combination of virus and filtrates in these cases also was found to accelerate the production of the disease.

It is known from the work of Ecker<sup>12</sup> that young culture filtrates of members of the colon-typhoid group are highly toxic and that there are essential differences among the toxic factors produced by the several members of this group (some markedly stimulate the intestine while others have little or no apparent effect).<sup>13</sup> Whether one or more of the several genuses, species and strains of organisms employed by Toomey is responsible for enhancing the effect of the virus, whether young rather than old culture filtrates will produce a similar result, whether there is a specific relationship between the virus and the colon-typhoid organisms, whether this is merely a nonspecific effect of a combination of two poisons—all these questions remain for future experimentation to decide.

Thus the gastro-intestinal tract may be a more important factor in poliomyelitis than has been believed heretofore. From Toomey's experiments it appears certain that poliomyelitis may be produced with the intestinal tract as a portal of entry. It remains yet to be proved beyond doubt that in human cases the intestine is actually the portal of entry. It is necessary to remember that the enteric tract of man has special peculiarities not possessed by those of the lower animals, including monkeys. The fact that a few cases of the disease have been produced in monkeys without resort to Toomey's expedient of isolating a loop of intestine between two clamps indicates that special conditions may make this unnecessary. Presumably this might be the case in man also, though whether more or less often than in monkeys it is impossible to say. The fact, however, that involvement of the sympathetic nervous system has been found to occur early in clinical

cases of the disease, often before any involvement of somatic nerves is apparent,<sup>14</sup> adds weight to this argument.

The ingenious and painstaking work of Toomey has revived and to a considerable extent substantiated Sicard's hypothesis that the poison characteristic of poliomyelitis may be absorbed by the gray fibers of the intestine and be carried by way of the sympathetic nerves to the spinal cord, but as with all really productive investigation it has raised many provocative, although as yet unanswerable, questions.

#### CURRENT PRODUCTION AND CONSUMPTION OF MILK

The intimate connection between economic difficulty in one field and the welfare of the individual whose immediate interest is perhaps far removed is illustrated in extreme degree by the dairy farmer on the one hand and the consumer of milk on the other. The importance of devising methods to help the producer is matched by the necessity of keeping available the supply of this indispensable food during these times of stress. Both the layman and the physician are vitally interested in the situation as regards the present supply and the consumption of milk in this country. A recent issue of the *Consumers' Guide*,<sup>1</sup> devoted to a survey of the national milk supply, sets forth certain significant facts.

The number of milk cows in this country has increased every year during the depression and in 1933 reached 26,000,000, the greatest in the history of the country. Two things have occurred which make it appear that there is an oversupply of milk: the price to the producer has dropped and great surpluses of manufactured dairy products have accumulated. Together with an apparent oversupply there is a shrinkage of the market. With the increasing population it is impossible to view this situation with anything but apprehension.

The unique importance of milk in the dietary has been fully established by investigators in nutrition during the past thirty years. Largely through the studies of Sherman and his cogent presentation of the results, there has been given to the human requirement for milk a quantitative expression. A quart of milk per child daily has become a by-word with practical workers in nutrition. How does the current per capita consumption compare with this standard or one based on it? Assuming that adults require less milk than children and that other suitable foods can be substituted in part for milk, the *Consumers' Guide* states that a minimum-cost adequate diet should provide 260 quarts of milk or its equivalent annually. "What we are actually getting is about 191 quarts a person a year—and

<sup>11</sup> Toomey J. A. Accelerated Production of Poliomyelitis. *Proc Soc Exper Biol & Med* 31: 1015 (May) 1934.

<sup>1</sup> *Consumers' Guide* issued by the Consumers' Council of the Agricultural Adjustment Administration. May 28, 1934.

this is an average, which means that lots of people are getting very much less." Similar evidence is provided by statistics issued by the Department of Agriculture,<sup>2</sup> in 1933 the daily per capita consumption of milk and cream in cities and villages was about 154 quarts.

Thus there is considerable discrepancy between the current consumption of milk and what it ought to be according to conservative expert opinion. Furthermore, the *Consumers' Guide* emphasizes the striking fact that, if the estimated liberal or adequate amount of milk were consumed, the present peak number of dairy cows would fall short of the required number by 15,000,000. The economic and, perhaps, political implications of this situation are evident, of fundamental and immediate concern, however, is the public health aspect of the restriction in the consumption of milk.

### THE LANGUAGE OF MEDICINE

The language of medicine is ever changing, thousands of words are added to its vocabulary each year. In a recent essay on "Language, Jargon, and Modern Medicine," Dr. Herbert R. Hurter<sup>1</sup> pointed out that even the English terms for "doctor" are not the best possible words for the purpose. He believes that the French *medecin* and the German *arzt* are better than medical practitioner, physician, doctor of medicine, leech, or such horrible terms as mediciner, medico or medic. The most ancient English term was of course "leech," but it lost its value when it was applied much more frequently to the little blood-sucking animal and began, by slang connotation, to become associated with the money lenders. The word "surgeon" has been with the profession 600 years and has been spelled thirty different ways. Etymologically it means a handy man—a well chosen word. The word "physician," it seems, has been spelled with an "f" and even with a "v" and today still includes those who do surgery as well as medicine. The word practitioner goes back certainly as far as four centuries, but general practitioner was not a well established term even eighty years ago.

Dr. Hurter pays special attention to the jargon of medicine. It must be remembered that the jargon and slang of today represent the established usages of the next generation. Yet for the vast majority of people the language of medicine is a closed book and not likely to be brought into daily conversation. New sciences acquire new words and, if the words seem to fit, they quickly come into the language. Almost every one today uses such words as antibody, acidosis, psychoanalysis, vitamin and endocrine, yet not one of these words is even fifty years old.

The main features of jargon in writing are pompous display, the use of long words when short ones are available, circumlocution and verbosity. Thus Hurter

points out that the sentence "The nurse gave him morphine hypodermically" is good English and can be understood by every one. However, "He was subjected by the nurse to the administration of a hypodermic injection of morphine" is jargon. Uses of the words "case" and "instance" are beautiful examples of overworked medical jargon.

Worse than medical jargon is medical slang. The best type of medical writing is that which appears in the case report. The use of the word "gut" for intestine or the plural of the word for the other contents of the abdominal cavity may be considered a medical affectation quite as bad as "the acute abdomen." When the surgeon says he did a "chronic appendix," when the gynecologist speaks of "an abdominal woman," when the dermatologist "puts the patient on iodides" or when the internist says the patient "runs a swinging temperature," they are speaking medical slang. The gynecologist would hesitate to speak of doing a Caesar when he performs a cesarean operation. These are some of the specific examples cited by Hurter, and there are many more in "The Art and Practice of Medical Writing."

In the field of medical science, many men have gained note by their ability to express themselves in good English succinctly, rhythmically and accurately. The opportunity is available, for every one who cares to take the trouble and the time, to perform competently in the field of medical letters. Experts assert that there are hardly a hundred competent medical writers in our country today, some authorities insist that there are hardly more than ten or twelve. In the field of preparation for sound literary expression, particularly, preliminary education to medical training seems to be failing miserably.

### Current Comment

#### THE INCIDENCE OF POLIOMYELITIS

Poliomyelitis in California seems to be dwindling definitely, according to the most recent statement from the United States Public Health Service. The number of cases in Los Angeles declined from a maximum of 156 for the week ended June 9 to 28 cases for the week ended August 18. In Los Angeles County the number of cases declined from 100 for the week ended June 16 to 31 for the week ended August 11. In San Francisco the maximum was 27 cases for the week ended June 23, with 7 for the week ended August 11. For the whole state of California, 466 cases were reported for the four weeks period ended August 11 and the total was 2,446 cases for the fifteen weeks from the beginning of the epidemic during the last of April to August 11. Of the total cases, 1,752 (or 70 per cent) occurred in the city and county of Los Angeles. In the meantime the incidence of poliomyelitis has increased in other states. During the thirteen weeks ended August 18 there were 218 cases in Washington, 73 in Montana, 61 in Idaho, 20 in Arizona and 23 in Oregon, as compared to from

1 to 7 cases in the same states over the same period a year ago Research on poliomyelitis continues, with the probability of the development of efficient methods of prevention some time in the near future

## Association News

### ANNUAL CONFERENCE OF STATE SECRETARIES

The Annual Conference of Secretaries of Constituent State Medical Associations will be held at the Palmer House, Chicago, September 21-22

The program will be as follows

FRIDAY SEPTEMBER 21 10 A M

Call to Order J H J Upham, chairman of the Board of Trustees of the American Medical Association  
Address Walter L Bierring, President of the American Medical Association  
The Medical Society of New Jersey Experiments in Furnishing Medical Services in the Community LeRoy A Wilkes, executive secretary of the Medical Society of New Jersey  
The Centralization and Departmentalization of State Medical Society Activities Oliver J Fay, chairman of the board of trustees of the Iowa State Medical Society  
The Work of the Committee on Mental Health H Douglas Singer, chairman of the Committee on Mental Health of the American Medical Association  
12 30 p m Recess  
12 45 p m Luncheon at Palmer House

FRIDAY SEPTEMBER 21 2 P M

Address James S McLester, President-Elect of the American Medical Association  
Medical Emergency Relief Holman Taylor, secretary of the State Medical Association of Texas, William C Woodward, director of the Bureau of Legal Medicine and Legislation of the American Medical Association  
Some Problems of a State Medical Editor W Edwim Bird, editor of the *Delaware State Medical Journal*  
Address R L Sensenich, member of the Committee on Legislative Activities of the American Medical Association

SATURDAY SEPTEMBER 22 9 30 A M

The Educational Possibilities of Scientific Programs at State and County Meetings Clyde L Cummer, president of the Ohio State Medical Association  
Health Insurance in England and Medical Society Plans in the United States R G Leland, director of the Bureau of Medical Economics of the American Medical Association

### MEDICAL BROADCASTS

#### Columbia Broadcasting System

The American Medical Association broadcasts on a Western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4 30 to 4 45, Central daylight saving time The next three broadcasts will be as follows

September 20 Infantile Paralysis W W Bauer M D  
September 27 Swimming Pool Sanitation, J F Hammond M D  
October 4 Autumn Leaves W W Bauer M D

The Most Glorious Epoch—The work of Pasteur a French chemist, Lister, a British surgeon, and Koch, a German district physician, marked for mankind the beginning of the most glorious epoch in the history of the world These convergent discoveries with many subsequent laboratory findings created and developed a scientific understanding of communicable diseases which led to an almost unbelievable evolution in the theory and practice of medicine—McFarlane Andrew The Family Physician—Past Present, Future, *New York State J Med* 34 579 (July 1) 1934

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC)

### ALABAMA

Health Unit Resumes Operation—Activities in the Coffee County health unit have been resumed, with the appointment of Dr William A Stanley, Union Springs, as health officer The unit was discontinued, Jan 1, 1933, on account of the lack of county funds

### CALIFORNIA

Dinner to Dr Bierring —Dr Walter L Bierring, Des Moines, Iowa, President, American Medical Association, was the guest of honor at a dinner at the Biltmore Hotel, September 4 sponsored by the Los Angeles County Medical Association The woman's auxiliary to the society was also present

Special Society Meeting —Three visiting speakers presented the program before the San Francisco County Medical Society at a special meeting, August 30 Henry F Vaughan, Dr P H, health commissioner of Detroit, on "The Family Physician and Preventive Medicine" Dr William W Bauer, Chicago, director, Bureau of Health and Public Instruction, American Medical Association, "Health Education by County Medical Societies," and Dr John E Gordon, epidemiologist of the Detroit Department of Health, "Trends in the Control of Communicable Diseases"

Society News —Members of the staff of Mount Zion Hospital presented the program before the San Francisco County Medical Society, August 14, speakers included Drs Harold H Rosenblum on "Rate of Blood Flow in Patients Receiving Diminophenol" and Felix L Pearl, "Angiospastic Claudication"—Dr James P Leake, surgeon, U S Public Health Service, Washington, D C, who is in California in connection with the epidemic of poliomyelitis, addressed the Hollywood Academy of Medicine, August 16—The Alameda County Medical Association was addressed, August 20, by Drs Mark L Emerson, Frank H Bowles and Archibald A Alexander on "Use of Histamine as an Indicator of Cutaneous Circulation in Leg Amputations," and by Drs Paul P E Michael and Vernon G Alderson, who discussed amebiasis

### COLORADO

Cancer Meeting —A special meeting of the Delta, Mesa and Montrose county medical societies in Delta, recently, was devoted to a symposium on cancer of the breast Drs John B Hartwell Colorado Springs, Carl W Maynard, Pueblo, and George A Unfug, Pueblo, represented the committee on cancer education of the Colorado State Medical Society A banquet preceded the session

Psychiatric Studies Expanded at University —Under a grant of the Rockefeller Foundation to the Colorado Psychopathic Hospital, Dr Edward G Billings has been appointed director of the liaison work between the departments of medicine and psychiatry in the Colorado General Hospital and assistant professor of psychiatry at the University of Colorado School of Medicine The grant was made to further educational and clinical activities and to effect a closer relationship between psychiatry and general medicine A five year demonstration period is anticipated Other new psychiatric appointments include Dr Clarke H Barnacle as resident psychiatrist at the psychopathic hospital, to succeed Dr William M Peake, who resigned to become assistant professor of psychiatry at the University of Cincinnati Medical School, effective September 1 Drs Jack R Ewalt, Henry W Brosn and Philip H Hearsma have been awarded fellowships in psychiatry at the hospital by the Commonwealth Fund, effective September 1

### GEORGIA

Personal —Dr Gabe W Willis, Ocilla, was recently honored when several friends gathered on the courthouse lawn to present him with gifts for his new hospital, which is nearing completion A musical program was a feature of the occasion —Dr Theodore Toepel Atlanta, has been awarded an honorary membership in the Fulton County Medical Society, members of the society who have reached the age of 65 and have had twenty-five years of consecutive membership are eligible for honorary memberships —A surprise birthday party was

given in honor of Dr Lewis Sage Hardin, Atlanta, August 1, at the Georgia Baptist Hospital

**Society News**—At a meeting of the Fourth District Medical Society at Warm Springs, August 1, speakers included Drs W Wilbur Blackman, Atlanta on acute gout, Ellis G Kirby, Bowdon, rabies, Thomas Neal Kitchens, Warm Springs, morphine poisoning, and Jefferson G Smith, McDonough zinc oxide cast for second and third degree burns—The Tenth District Medical Society was addressed at Washington, August 8 among others, by Drs John W Brittingham, Augusta, cardiovascular syphilis Robert C McGahee, Augusta, congenital syphilis, William Perrin Nicolson Jr, Atlanta, breast lesions James M Hull, Augusta, medical care of cataracts and William J Cranston, Augusta, gastric neuroses—Speakers before the Burke-Jenkins-Screven Counties Medical Society at Millen August 2, were Drs Henry G Lee, Millen on diseases of the endocardium, and Cleveland Thompson, Millen, arachnoidism

### ILLINOIS

**Campaign Against Impure Milk**—State officials have launched a campaign against the sale of impure raw milk which is now being dispensed at roadside stands and milk depots in Illinois, according to the *Chicago Tribune*. Efforts have been concentrated in suburbs outside of Chicago, it was stated, where, in many cases the milk depots do not come under the jurisdiction of municipal health authorities. It was pointed out that about 80 per cent of the depots investigated do not measure up to the sanitation standards of the state dairy and food division

#### Chicago

**Personal**—Dr Leo K Campbell has been appointed assistant clinical professor of medicine at Rush Medical College—A stag party was held at the Army and Navy Club, September 5, in honor of Major Lorin A Greene medical officer sixth corps area, who is being transferred to foreign service in the Philippines. A dinner was also given in his honor recently at the Glenview Country Club. At this occasion Dr Cleveland C MacLane was notified of his promotion to colonel in the medical reserve

### INDIANA

**Exhibits at State Fair**—Exhibits and demonstrations in the Good Health Building at the State Fair September 1-7 were sponsored by the Indiana State Medical Association the Indiana State Dental Association the state hospital and tuberculosis associations and the Indianapolis College of Pharmacy

**Courses in Tuberculosis**—August 30 marked the opening of a series of short courses in tuberculosis for physicians by the Indiana Tuberculosis Association. The first was held at the Boehne Tuberculosis Hospital, Evansville, for two days. Others in the series comprise the following

Indiana State Sanatorium Rockville October 23  
Irene Byron Sanatorium Fort Wayne October 17 18  
Lake County Tuberculosis Sanatorium Crown Point October 18 19  
Sunnyside Sanatorium Oaklandon October 22 23  
William Ross Sanatorium Lafayette dates to be announced later

There is no fee for these courses. Further information may be had from the Indiana Tuberculosis Association, Room 1219 130 East Washington Street, Indianapolis

**Outbreak of Encephalitis in Evansville**—At least seven deaths are known to have occurred from encephalitis in Evansville during the past week, according to the *Chicago Tribune*. Cases of encephalitis have been reported in Hartford City Shelbyville, Petersburg and Muncie. Steps have been taken to prevent the further spread of the disease. An investigation is being made to determine whether the type of disease in the Indiana outbreak is the same as that of the St. Louis epidemic which occurred last year and which is fully discussed in the present and the preceding issues of THE JOURNAL. The state health department and the U S Public Health Service are cooperating in controlling the outbreak. Four fatalities were recorded for Providence, Ky, and nine persons were said to be ill

### IOWA

**Dr Leech Honored**—Dr Louis J Leech, West Branch, was honored, August 3, when hundreds of friends assembled to observe his eighty-eighth birthday and his recent election to commander of the Iowa department of the Grand Army of the Republic. A musical program featured the occasion. Dr Leech was presented with an initialed traveling bag. He graduated from the State University of Iowa College of Medicine in 1881 and has been practicing in and about West Branch since that time

### KANSAS

**Play Day**—September 21 will be observed in Wichita as "Doctors' Play Day" in accordance with a proclamation issued by the mayor, Schuyler Crawford

**Annual Registration Due October 1**—All physicians and surgeons holding licenses to practice in Kansas are required to renew their licenses annually and to pay an annual fee of \$1, between July 1 and October 1, to the secretary of the board of medical registration and examination. The secretary must strike from the register of licensed physicians the names of all physicians who fail to pay their annual registration fees as required by law. Physicians whose names are so removed may be reinstated by paying the secretary \$5 and submitting to him satisfactory proof of moral fitness

### KENTUCKY

**State Medical Meeting at Harlan, October 1-4**—The Kentucky State Medical Association will hold its annual meeting in Harlan October 1-4, with sessions in the Methodist Episcopal Church. The annual oration in medicine will be delivered by Dr William J Shelton, Mayfield, on "The Mutual Interest of Physicians and Patients." Dr Kemon Dunham Cincinnati will address a public meeting on "Pulmonary Emphysema A Sequela of Pulmonary Tuberculosis," and Dr William D Haggard, Nashville, the same session, on "The Management of Goiter and Results in One Thousand Operative Cases." Dr Isaac A Arnold, Louisville, will deliver the oration in surgery on "The Fracture Problem—Present and Future Status." Other physicians on the program include the following

William Woodward Nicholson Louisville Lead Poisoning in Children  
William Edgar Fallis Louisville Appendicitis in Children  
James W Bruce Louisville Treatment of Diarrhea in Infancy  
Ellis S Allen Louisville Diagnosis and Treatment of Congenital Pyloric Stenosis  
Lucien Lyne Smith Louisville Feeding the Diabetic  
Frank M Stites Jr Louisville Amebiasis  
John L Edwards Lancaster Treatment of the Tuberculous in the Home  
Arthur Clayton McCarty Louisville Newer Aspects of Arthritis  
R Alexander Bate Louisville Endocrine Vitamin and Allergen Relativity  
Adolph O Pfingst Louisville The Wearing of Glasses—As It Relates to Medicine  
Ernest B Bradley Lexington Treatment of Tetanus  
Thomas J Crice Louisville Drug Addicts  
Curran Pope Louisville Further Studies and Observations of Hyperthermia (Fever Treatment)  
Charles G Melcan Lexington Trend of Modern Medicine  
William B Atkinson Campbellsville The Business Side of Medicine  
Franklin Jelsma Louisville Spinal Cord Tumors Symptomatology and Differential Diagnosis  
Louis Frank Louisville Cancer of the Uterus  
Francis M Massie Lexington End Results of Plastic Surgery  
William O Johnson Louisville Study of 100 Cases of Ectopic Pregnancy  
Rufus C Alley Lexington Internal Hemorrhoids Treatment by Nonsurgical Methods  
William J Martin Jr Louisville Etiology and Surgical Treatment of Anal Fistula  
John M English Elizabethtown A Plea for Better Obstetrics  
Charles G Daugherty Paris Chorea in Pregnancy  
Harry M Weeter Louisville Laboratory Tests for Pregnancy  
David Y Keith Louisville Malignant Tumor of the Thorax and Upper Abdomen

Sessions on Tuesday and Wednesday will be devoted to round tables by the following physicians: Philip F Barbour, Louisville, Henry G Reynolds, Paducah, Virgil E Simpson, Louisville, John H Blackburn Bowling Green, Morris Flexner, Louisville, Edward Sperdel, Louisville, William Barnett Owen Louisville, and Lillian H South, Louisville

### MICHIGAN

**Dr Warnshuis Honored**—The Ingham County Medical Society gave a farewell dinner in honor of Dr Frederick C Warnshuis in Lansing, August 14, following his resignation as secretary of the Michigan State Medical Society to become secretary and director of public relations of the California Medical Association. Speakers included Drs Leo G Christian Russell L Finch, J Earl McIntyre all of Lansing, James O Meara Jackson, and James B Bradley, Eaton Rapids. Dr Warnshuis was made an honorary member of the society and presented with a leather traveling bag

### MISSOURI

**Health and Tuberculosis Meeting**—The Missouri Public Health Association and the Missouri Tuberculosis Association will hold their annual sessions jointly at the Jefferson Hotel, St. Louis September 19-21. Speakers to be heard at the various sessions include Drs Thurman B Rice Indianapolis and Kendall Emerson New York

**Kansas City Clinical Conference**—The twelfth annual fall clinical conference of the Kansas City Southwest Clinical Society will be held at the President Hotel, Kansas City, October 14. Guest speakers include the following:

Dr. Walter L. Biering, Des Moines, Iowa, President American Medical Association, Acute Diseases of the Blood Forming Organs  
Medical Societies of the Future, Heart Disease in General Practice  
Dr. Hugh Cabot, Rochester, Minn., Newer Conceptions of Diagnosis and Treatment of Infections of the Urinary Tract, Standards of Modern Medicine, Management of the More Difficult Cases of Renal Calculus  
Dr. Joseph B. De Lee, Chicago, sound motion picture on Forceps Operation  
Dr. Morris Fishbein, Chicago, Organization of American Medicine, The Doctor's Hobby, Trend of Medical Practice  
Dr. Lee F. Hill, Des Moines, Certain Phases in the Management of Infectious Diseases, Rums and Babies  
Dr. Samuel Glauber, Cincinnati, Deep Infections in the Neck and Mediastinum, Has Organized Medicine Taken a Proper Attitude Toward the Social Aspects of Medicine?  
Dr. Samuel A. Levine, Boston, Boston Clinical Significance of a Systolic Murmur, Factors in Prognosis in Heart Disease, Thyroidectomy in the Treatment of Intractable Heart Disease, The Doctor's Heart  
Dr. Henry O. Mertz, Indianapolis, The Urologist's Contribution to the Differential Diagnosis of Abdominal Conditions, Urology in Children  
Dr. Philip Lewin, Chicago, Classification, Etiological Factors and Treatment of Arthritis  
Dr. George E. Pfahler, Philadelphia, Diagnosis and Treatment of Cancer of the Breast, Oral Cancer, Its Diagnosis and Treatment, Cancer—What Is It?—How Can We Prevent It?—What Shall We Do for It?  
Dr. Fred W. Rankin, Lexington, Ky., Hyperparathyroidism, Modern Management of Cancer of the Large Bowel and Rectum, Selection of Peptic Ulcers for Surgical Treatment, The Surgeon of the Future  
Alphonse M. Schwitalla, S. J., Ph. D., St. Louis, How a Man Becomes a Physician, Controlling the Output of the Embryo Physician  
Dr. Harry W. Woodruff, Joliet, Ill., Eye Injuries and the General Practitioner

In addition to these speakers, addresses will be given by twenty-three members at the general assembly and sectional meetings.

## NEBRASKA

**Annual Registration Due October 1**—All practitioners of medicine and surgery holding licenses to practice in Nebraska are required by law to register annually, on or before October 1, with the department of public welfare and to pay a fee of \$1. A license expires if the licensee fails to register. Within the thirty days next following its expiration, however, it may be revived and kept in force by the payment of the registration fee and a penalty of \$1. If that is not done an order of revocation is issued.

**Society News**—Dr. David M. Berkman, Rochester, Minn., addressed the Madison-Six Counties Medical Society, Norfolk, July 17, on "Classification of Albuminurias for Clinical Use." A joint meeting of the Brown County (Kansas) and Richardson County medical societies in Falls City, recently was addressed by Drs. William G. Emery, Hiawatha, Kan., on county health work, and Henry J. Deaver, Sabetha, Kan., complications of pneumonia. Speakers before the Five County Medical Association in Homer, July 2, included Drs. Arthur E. Cook, Randolph, on influenza and Walter Benthack Wayne on abdominal diagnosis. The Madison County Medical Society was addressed at Norfolk, July 17, by Drs. David M. Berkman, Rochester, on medical economics, and Lucien Stark, Norfolk, on diagnosis and classification of kidney disease.

## NEW JERSEY

**Child Health Survey**—The results of a five month survey of child health in New Jersey have been made available. Carried on as a CWA project by the state department of health under the direction of the child hygiene bureau, its purpose was to determine to what extent certain health protective measures had been employed in various parts of the state, such as medical health examinations, dental health examinations, immunization against diphtheria and vaccination against smallpox. In addition, data were obtained in regard to the incidence of certain contagious diseases among children of preschool age. A total of 273,546 families were visited, from whom 59,311 completed questionnaires were obtained. It was found that 163,678 or 73 per cent of the total number of families visited had no children under six years of age, to whom the survey was confined. The report shows 354 communities in twenty one counties were surveyed and that 24.6 per cent of these communities had 30 per cent of their children immunized against diphtheria, 18 per cent had 20 to 30 per cent, 31.4 had 10 to 20 per cent and 26 per cent had less than 10 per cent of their children immunized. Two counties, Essex and Union, had, respectively, 75 and 65 per cent of their communities with more than 30 per cent of their children immunized against diphtheria. Essex County, the largest urban county, stands first in all three child health protective mea-

sures presenting 46.1 per cent immunized against diphtheria, 36.9 vaccinated against smallpox, and 82.2 who have had a physical examination. Warren County, rural, presents the poorest record in regard to diphtheria immunization, appearing twenty-first with but 6.5 per cent immunized. Hunterdon County, rural, presents the poorest record in smallpox vaccinations, showing 4.5, while Cumberland County was poorest in child health examinations, presenting but 20 per cent. Of 205,473 children under 6 years of age, records show that 27.4 per cent have been immunized against diphtheria, and 23 per cent vaccinated against smallpox.

## NEW YORK

**Personal**—Dr. James L. McCartney, director of the Classification Clinic at Elmira Reformatory since 1931, has resigned to enter private practice in Portland, Ore. Dr. McCartney organized the clinic at Elmira.

**Cancer Exhibit at State Fair**—The prevention and treatment of cancer was the theme of the health exhibit at the state fair at Syracuse, recently. One feature of the exhibit portrayed the cases successfully treated at the State Institute for the Study of Malignant Diseases at Buffalo. Cooperating in the exhibit were the division of public health education of the state department of health, the institute and the American Society for the Control of Cancer.

**Septic Sore Throat from Contaminated Milk**—An outbreak of twenty or more cases of septic sore throat occurred between July 22 and August 13, *Health News* reports. All persons known to have been ill had used raw milk from a supply furnished by one dealer. Investigation revealed that a milker of the dealer's farm had had an infected finger and had milked six cows each night and morning until August 5, when he was obliged to stop working because of pain and swelling in his hand.

## New York City

**Annual Etching Exhibit**—The Haden Etching Club will hold its third annual exhibition at the Leonard Clayton Galleries, October 1-13. The closing date for entering prints is September 20. Only members are entitled to exhibit. Information may be had from Dr. Benjamin F. Morrow, 162 West Fifty-Sixth Street. The Haden Etching Club is an organization of dentists and physicians.

**Course in Psychoanalysis**—The New York Psychoanalytic Institute announces an introductory course in psychoanalysis for physicians, consisting of fourteen lectures on "Psychoanalysis in Medicine." Lecturers will be Drs. Clarence P. Oberndorf, George E. Daniels, Sydney N. Lorand and Philip R. Lehman. The lectures will begin October 4 and continue on successive Thursdays, omitting November 29. Registration may be made with Dr. Monroe A. Meyer at the institute, 324 West Eighty-Sixth Street.

**New York Graduate and Stuyvesant Hospitals Join Forces**—An affiliation between the New York Post-Graduate Medical School and Hospital of Columbia University and the Stuyvesant Square Hospital was made effective September 1. Under the agreement, the Stuyvesant Square Hospital will maintain its identity. Membership of the board of directors of the graduate hospital will be extended to include members of the present directorate of the Stuyvesant institution. The latter will retain the control of its capital funds, including any funds subsequently received by gift or bequest for maintenance or endowment of beds, while the graduate hospital will take over the management and maintenance of buildings and equipment and the general administration of the hospital, funds for which are provided from the income of the Stuyvesant Square Hospital. The properties of the two affiliated institutions are contiguous. Stuyvesant Hospital is said to be the oldest cancer hospital in America, while New York Post-Graduate is described as the first exclusively graduate school of medicine in the world, and the teaching facilities of its general hospital are available only for the graduate physician. Both institutions were founded in 1882.

## OHIO

**State Medical Meeting at Columbus, October 4-6**—The eighty-eighth annual meeting of the Ohio State Medical Association will be held at Neil House, Columbus, October 4-6. Out of town speakers will include Drs. Rollin T. Woodyatt, Chicago, on "Diabetes Mellitus", Charles P. Emerson, Indianapolis, "Psychoneurotic Reactions", Albert C. Furstenberg, Ann Arbor, "Meniere's Symptom Complex, Medical Treatment" and Mark J. Schoenberg, New York, "Recent Additions to the Clinical Study of Intra-Ocular Pres-

sure and Glaucoma" Dr Russell L Cecil, New York, will conduct a clinic on chronic arthritis Ohio physicians participating in the program will include

Mont R Reid Cincinnati Recent Advances in the Treatment of Peripheral Vascular Diseases  
Albert F Kuhl Dayton Ambulatory Treatment of Rheumatic Heart Disease

Russell L Haden Cleveland Hypochromic Anemia  
Louis Feid Jr Cincinnati Treatment of Benign Uterine Bleeding  
Frederick M Douglass Toledo Management of Common Duct Stone and Obstruction

William Kelley Hale Wilmington General Treatment of the Cancer Patient with Special Emphasis on Maintaining the Normal Blood Picture

Charles T Souther Cincinnati Technic for Intestinal Anastomosis  
John Hart Davis Cleveland Clinical Aspects of Alkalosis  
Stanley D Giffen Toledo Clinical Relationship Between Color of Nasal Septum and Various Biochemical and Endocrine States in Children

Andrews Rogers Columbus Influence of the Upright Position on Pregnancy and Parturition

Alphonse R Vonderahe Cincinnati, Representation of Visceral Function in the Brain

Louis A Lurie Cincinnati Role of Glandular Therapy in the Treatment of Behavior Disorders of Children

Paul M Holmes Toledo Medicolegal Aspects of Silicosis

Arthur G Cranch Cleveland Hypertension with Relation to Capacity for Work

Finley Van Orsdall Columbus Development of Preventive Medicine

The annual dinner will be held Friday evening at the Neil House, with Gustavus W Dyer, Ph D, professor of economics, Vanderbilt University, Nashville, Tenn, as the principal speaker The annual golf tournament will be held, October 3, at the Columbus Country Club, while the Ohio State-Indiana football game is scheduled for Saturday afternoon, October 6

## PENNSYLVANIA

**Campaign Against Appendicitis**—The Chester County medical and tuberculosis societies are cooperating in a campaign to reduce appendicitis mortality and maternal morbidity Seventeen meetings are planned for October and November

### Philadelphia

**Personal**—Dr Martha Tracy, dean, Woman's Medical College of Pennsylvania, was recently elected a fellow of the College of Physicians of Philadelphia the second woman to be so honored The first was Dr Catharine MacFarlane, professor of gynecology at the college—Dr James M Anders celebrated his eightieth birthday, July 22

**Tuberculosis Conference**—The development and progress of the tuberculosis movement in recent years and present-day activities to control the disease will be considered in a conference to be held at the Bellevue Stratford Hotel, Philadelphia, October 18, under the auspices of the Pennsylvania Tuberculosis Society and the Philadelphia Health Council and Tuberculosis Committee, in cooperation with nearby county tuberculosis organizations Speakers at the conference will include Drs Charles J Hatfield, executive director of the Henry Phipps Institute and president of the Philadelphia Health Council, and Dr Kendall Emerson, New York, managing director of the National Tuberculosis Association One session especially for physicians will consider "The Child" Speakers will be Drs William Charles White Washington, D C, Paul B Kreitz, Bethlehem, and Esmond R Long

## VIRGINIA

**State Medical Meeting at Alexandria**—For the first time in more than fifty years the Medical Society of Virginia will meet in Alexandria, October 9-11 This will be the sixty-fifth annual session, headquarters will be at the George Mason Hotel Included on the scientific program will be the following physicians

Harry Walker Richmond Treatment of Obesity  
James Morrison Hutcheson Richmond Medicolegal Aspects of Apoplexy

Frank A Strickler University A Study of Convulsive Disorders at the University of Virginia Hospital since 1920

Thomas Dewey Davis Richmond The Irritable Colon

Regena C Beck Richmond Drug Idiosyncrasy and Neutropenia

Douglas G Chapman Richmond Total Thyroidectomy for Chronic Heart Failure

Henry B Mulholland University Diagnosis of Rocky Mountain Spotted Fever of the Eastern Type

James Coleman Motley Ahingdon Wandering Spleen with Erosion of Its Pedicle

Robert DuVal Jones Jr Norfolk Leiomyoma of the Gastro Intestinal Tract

Charles R Rohins Richmond Cure of Direct Inguinal Hernia

Claude C Coleman and William G Crutchfield Richmond Observations in the Treatment of Acute Head Injuries

John M Emmett Clifton Forge Fifteen Hundred Spinal Anesthetics with Special Reference to Indications Complications and Mortality

Guy W Horsley Richmond Surgical Treatment of 183 Consecutive Thyroid Cases with No Mortality

Charles S White and James Lloyd Collins Washington D C Evipan Anesthesia

John S Weitzel Richmond Problems in Breast Feeding

Harry J Warthen Richmond Gas Bacillus Infections Study of the Incidence Treatment and Mortality

Martillius H Todd Norfolk Colles Fracture

Joseph H Hiden Pungoteague Experience with an Efficient Method of Operation for Hemorrhoids Adapted to General Practice in Rural Districts

Beverley R Tucker Richmond Neuropathology of Pellagra in Its Relation to the Cutaneous and Other Manifestations

Joseph F Geisinger Richmond The Cystic Kidney

James G Iyerly Richmond Brain Tumors in Children

James P Baker Anemias Dependent upon Food Deficiencies

Harry Hudnall Ware Jr Richmond, Extra Uterine Complications of Pregnancy

James Edwin Wood Jr George D Capaccio and William N Weaver University Venous Pressure and Body Weight Determinations in Congestive Heart Failure

Claude Moore Washington D C Pathologic Lesions Correctly Diagnosed by Roentgenologic Methods and Later Missed at Surgical Exploration

William W Falkener Newport News J Shelton Horsley Richmond and Thomas D Walker Jr Newport News Vomiting in the New Born with Special Reference to Congenital Occlusion of the Duodenum

James B Nicholls and Lemuel R Broome Catawba Sanatorium Collapse Therapy in Pulmonary Tuberculosis

There will be a symposium on medical economics with the following speakers Dr James C Flippin, University, Dr Walter B Martin, Norfolk, Dr Irl C Riggan, Richmond, and Edgar Sydenstricker of the Milbank Memorial Fund, New York

## WASHINGTON

**Society News**—The Pierce County Medical Society was addressed in Tacoma, August 28, by Henry F Vaughan, Dr P H and Dr John C Gordon, health commissioner and epidemiologist, respectively, of the Detroit Department of Health, their subjects were "The Family Physician and Preventive Medicine" and "Trends in Control of Communicable Diseases"

## GENERAL

**Roentgenologists' Meeting**—The American Roentgen Ray Society will hold its annual meeting at the William Penn Hotel Pittsburgh, September 25-28, under the presidency of Dr George W Grier, Pittsburgh Dr Walter B Cannon, Boston, will deliver the Caldwell Lecture, Tuesday evening, September 25 Symposiums will be presented on high voltage roentgen therapy and on encephalography Among others on the program will be

Dr Albert E Bothe Philadelphia Effect of X-Ray Therapy upon Mixed Tumors of the Kidney in Children

Dr Walter L Mattick Buffalo Our Changing Conceptions Regarding the Skin Dose

Dr Stuart W Harrington, Rochester Minn Diagnosis and Surgical Treatment of Intrathoracic Tumors

Dr Pedro Fariñas Havana Cuba Serial Bronchography in the Diagnosis of Pulmonary Suppurative Processes

Drs George W Holmes and Richard Schatzki Boston Demonstration of the Mucosa of the Gastro Intestinal Tract

Drs Willis F Manges and Louis H Cleit Philadelphia Congenital Anomalies of the Alimentary Tract

Dr Chester H Warfield Chicago Roentgen Diagnosis of Aneurysms of the Innominate Artery

Drs Edward C Vogt and James M Baty Boston Leukemic Bone Changes with Differential Diagnosis

**Occupational Death Rates**—In a study made by the National Tuberculosis Association based on data furnished by the U S Bureau of the Census the highest death rate among working men 15 to 64 years of age was found among hostlers and stable hands, 36.22 deaths per thousand employed Other high rates were operatives in harness and saddle factories, 30.55, aviators, 28.73, sailors and deck hands 17.28 Low rates were found for teachers, 4.42, and social and welfare workers, 2.75 The general rate for all "gainfully employed males" was 8.7 per thousand Among professional men, physicians and surgeons showed a rate of 10.69, clergymen, 10.33, lawyers, judges and justices, 7.89, college presidents and professors, 2.69 Unskilled workers commit suicide in greater proportion to their numbers than professional men, and agricultural workers less than semi-skilled workers in other pursuits Tuberculosis takes the greatest toll among the unskilled Heart disease claims more than the average of professional men unskilled workers also have a high rate, but the rate for agricultural workers is only half the average Rates for numerous other occupations and detailed rates for different diseases are given in the final report

## CORRECTION

**Conservative Treatment of Late Toxemias of Pregnancy**—On page 551 of the article on this subject by Dr L G McNeile (THE JOURNAL, August 25) appears an error in dosage The article reads "Patients who are very restless should be given chloral hydrate, 20 Gm, and sodium bromide 60 Gm, by rectum" This should read "20 grains of chloral hydrate and 60 grains of sodium bromide"

## Foreign Letters

### LONDON

(From Our Regular Correspondent)

Aug 18, 1934

#### Nonsurgical Drainage of the Biliary Passages

In a lecture at Guy's Hospital, Dr A F Hurst described how in the medical school the method of nonsurgical drainage of the bile passages had been developed from American observations. In 1917 Meltzer found that magnesium sulphate introduced into the duodenum leads to contraction of the gallbladder and biliary ducts with relaxation of the sphincter of the common bile duct (Oddi's sphincter). Two years later this discovery was practically applied by Lyon of Philadelphia, who showed that a specimen of bile could be obtained for diagnostic purposes through a duodenal tube after injection of magnesium sulphate. He subsequently proposed the same method for "nonsurgical drainage" of the gallbladder and bile ducts, but Dr J F Venables of Guy's Hospital found that it was unnecessary to use a duodenal tube as an equally good flow of bile was obtained if the salt was taken in concentrated solution by mouth during fasting. As biliary stasis is one of the chief factors in the pathogenesis of cholecystitis, cholangitis and gallstones, Dr Hurst considers administration of magnesium sulphate every morning a valuable method of treating disorders of the bile passages. The dose should be the largest the patient can take without causing looseness of the bowels. Some patients can take only half a teaspoonful but others as much as a tablespoonful. Incidentally two members of the staff of Guy's Hospital, Mr E G Slesinger and Mr Frank Cook when students in the physiologic department, carried out some observations with Dr Hurst, which showed that the old idea that a saline aperient acts by draining water into the bowel is wrong, as the watery stool passed an hour after taking it contained none of the salt, about half of which was found in the formed stool passed next day. The remainder was excreted in the urine within eight hours of being taken. As the salt had not reached the colon by the time the watery stool was passed the only possible explanation is that saline aperients are absorbed from the small intestine and act from the blood by stimulating the secretory activity of the colon, the distention of which results in evacuation.

Olive oil, according to Dr Hurst, has exactly the same effect on the bile passages as magnesium sulphate when introduced into the duodenum. It has the further effect of reducing the hyperchlorhydria that is present in those cases of cholecystitis which simulate duodenal ulcer. A tablespoonful should be given three times a day before meals. Dr Hurst recommends that magnesium sulphate and olive oil should be taken for several weeks after cholecystectomy as they help the common bile duct and Oddi's sphincter to adapt themselves to the new anatomic conditions and thus prevent the indigestion and occasional attacks of biliary colic that otherwise may occur.

#### The Village Settlement for Tuberculous Patients

The important advance of recent years in the treatment of tuberculosis is the village settlement, where it has been shown that patients in a new and suitable environment can recover health, support themselves and live with their families without danger to the latter. This method was originated by Sir Pendrill Varrier-Jones, who founded the first village settlement at Papworth, near Cambridge. In an article contributed to the *Daily Telegraph* he points out that the sanatorium cannot cure any but early cases of tuberculosis. Yet two thirds of the beds are occupied by middle and advanced cases for whom cure is out of the question. Many of these unfortunates, patched up by a few months of sanatorium treatment, are sent

back to the environments in which they contracted the disease, armed with perfectly sound advice which they cannot possibly follow. Either they find work that overstrains their damaged physique or they do not, in which case they suffer from anxiety and malnutrition. They relapse and die after infecting relatives and friends. The remedy found by Varrier-Jones is obvious. Give them the environment they need. Give them work graduated to their physical capacity, in light, airy workshops equipped with machines to do the heavy work they cannot do. Enable them to live in home conditions approximating as closely as possible those of a sanatorium. This has been done successfully at Papworth, with its hospitals, sanatoriums and village settlement. From small beginnings it has grown until today its medical buildings contain 415 patients, and a village population of some 500 persons is maintained by the work of its tuberculous bread winners, who are earning wages amounting to \$100,000 a year, incurring little or no revenue loss in the process. Children have been born to tuberculous parents and have grown up free from disease. Tuberculous men and women have fashioned for themselves new careers in their new environment with great advantages physical and financial to themselves and the public. Families thus voluntarily and agreeably segregated do not spread infection among the community. The capital cost of the scheme is balanced by its saving. It cuts the vicious circle of infection. It stops the cruelty implicit in tendering impracticable advice. It robs tuberculosis of its worst economic terrors.

#### An International Pharmacopeia

Presiding at the British Pharmaceutical Conference, Dr C H Hampshire emphasized the need for an international pharmacopeia. For the same reasons that led this country to demand a British Pharmacopeia there had arisen from time to time a desire for the unification of the standards for drugs and of the strengths and formulas of preparations through the medium of an international pharmacopeia. The advantages of such uniformity on the continent of Europe were obvious. Differences in national standards for widely used materials were a hindrance to the spread of medical knowledge, an inconvenience to pharmacists in dispensing prescriptions brought from various countries, and a source of trouble and possibly of danger to travelers. The unification of assay methods, of manufacturing standards and of processes was an object worthy of enthusiasm. The formation of a permanent central organization to keep the various national commissions in touch with one another, to arrange for collaborative investigations and to collect and distribute reports on pharmacopoeial revision was urgently necessary and would do much to bring about the desired result.

#### Medical Services for South African Natives

The medical needs of four million Bantus living in the native reserves of the South African Union furnish a problem of some urgency. Six years ago a commission was appointed to inquire into the practicability of training Bantus in medicine to serve their own people. It was pointed out that in some areas there was only one physician for 40,000 people and that native herbalists and witch doctors flourished. The committee recommended a full course of medical training for natives at one of the South African universities, but the government considered this impracticable. It is now arranging a special training of suitable natives in a shortened course not leading to medical qualification. Those so trained will be called "native medical aids." The training will differ fundamentally from the medical curriculum in that it will not be concerned with principles. The "medical aid" will be trained to do a limited number of duties well—first aid treatment and the preparation of blood smears for malaria examination, of nasal smears for leprosy examination, and of sputum for tuberculosis examination. He is to be made capable of treating most of the ordinary ailments

and injuries and of knowing when to call in a physician. He will be in full time government employ, and private practice will be precluded. He will be given a house considerably superior to the huts of the kraal where he will be stationed and will have a dispensary and consulting room. It is contemplated that 200 native medical aids will be provided at a cost to the state of \$350,000 per annum.

#### The Education of Partially Sighted Children

The board of education has issued a report on the education of partially sighted children. Schools for them are of much more recent origin than schools for the blind. They began in 1908 with the formation of a 'myope class' in London, and the policy of schools for the partially sighted has since rapidly spread all over the world. Myopia is by far the most important condition for admission to these schools. It is generally held that faulty posture in reading and writing, poor illumination and excessive convergence of the eyes such as may occur in reading small print or doing fine needlework, increase myopia and are only too common in ordinary schools. Evidence was given by ophthalmic surgeons that rapid progress of myopia may be arrested if close work is stopped and attention given to the general health. By reducing the factors causing undue stress on the eyes some decrease or arrest of the progress of the myopia can be produced, but the result is not always permanent. Some evidence was given that the educational restrictions due to attendance at a special school were not always justified by the results. The committee arrived at the following conclusions: 1. If the eyes show fundus changes indicative of serious myopia, the child should always be admitted to a special school. 2. In the absence of such changes the child should usually be admitted if (a) after repeated examinations the myopia is found to be increasing at the rate of more than 1 diopter per annum, (b) after a period of slow rate of increase or apparent arrest there is a sudden rise in the rate of progress to more than 2 diopters per annum. 3. The actual amount of myopia should not be the sole factor in determining whether or not a child should be sent to a special school. 4. The age of the child must be taken into account. The younger the more serious are factors such as the degree of myopia and its rate of progress. In doubtful cases the history of myopia in the family may be a deciding factor. 5. Myopic children with a visual acuity after correction of 6/24 or less should be admitted to a special school. Children suffering from damaged eyes due to the disease should not be admitted to these schools so long as there is any inflammation.

#### THE EDUCATIONAL PROGRAM

Great difference of opinion was manifested with regard to this. One view was that the danger to the sight of myopic children from reading was so great that they should be discouraged from it as much as possible. Another school would allow books under carefully guarded conditions, holding that the risk was not so great as to justify the loss of educational advantages. The committee took a middle course. It recommended that under the age of 8 books should be sparingly used and the main work done on blackboards, which should be supplemented with books printed in 24 point type as far as is advisable. For older children 18 point type need not be prohibited entirely.

#### EMPLOYMENT

The partially sighted are more likely to become unemployed than are those without this disability. But with good personal qualities they can sometimes work their way into permanent posts of value. The committee is averse to specific vocational training, such as is given to the blind. The object should be to educate these children, as far as possible, to compete on equal terms with others.

#### Legislation Against Sex Offenses in the Irish Free State

A bill has been passed in the dail of the Irish Free State making the penalties for sexual offenses more severe. As the law stood, it was a felony to have intercourse with a girl under the age of 13 years and a misdemeanor to attempt it. The present bill raises the age to 15 years. By previous acts it was a misdemeanor to have or attempt intercourse with a girl above the age of 13 years but under the age of 16 years. The bill raises these ages to 15 and 17 years respectively. Another section of the bill makes it an offense for a prostitute to loiter in any street or thoroughfare for the purpose of solicitation. For the first offense the penalty is a fine not exceeding \$8, for the second imprisonment for a term not exceeding six months. It is also made unlawful to sell or expose for sale, advertise or import any contraceptive. The penalty is a fine not exceeding \$250 or imprisonment for a period not exceeding six months or both. In the debate it was pointed out that while the majority of the Irish people condemned the use of contraceptives as immoral, there were many who did not share this view. A virtuous married woman was often faced with the advice that pregnancy might endanger her life or injure her health. She had no other alternative but abstention from intercourse or contraceptive precautions. Abstention might be almost impossible or lead to grave nervous disturbance and unhappiness in both husband and wife. It was argued that to deny an alternative to those whose consciences allowed them to adopt it was unjust. Nevertheless, this clause of the bill was passed.

July 25, 1934

#### Phonendoscopy and the Diagnosis of Perivisceritis

Articles have appeared recently in regard to certain signs that may aid in the diagnosis of subhepatic perivisceritis. Lardennois called attention to the significance of pain in the right hypochondrium elicited on raising the arms. Lyon discovers subhepatic adhesions with the aid of a tuning fork. A stethoscope is placed on the inner side of the left costal border, and the base of the tuning fork is shifted from the median line toward the axillary line and along the right costal border. Normally the sound thus elicited is weak and far different from the gastric sound which is clear and intense when the tuning fork is placed over the stomach in the left portion of the epigastrium. The gastric sound on the contrary, is heard when the tuning fork is over the ninth or tenth rib if there are peripyloric and perivesicular adhesions. If the adhesions are dense and extend to the ascending colon and the cecum, the gastric sound is heard even when the tuning fork is placed on the axillary line. Ferrabouc and Jude, on studying the transmission of sound produced by a tuning fork the base of which rests on the abdominal wall observed that, in perivisceritis of the right side, the sound is transmitted better between the epigastrium and the right iliac fossa than between the epigastrium and the left iliac fossa. They explained the following technic before the Societe medicale des hopitaux. The stethoscope being on the epigastrium halfway between the umbilicus and the xiphoid appendix, the vibrating tuning fork is carried several times back and forth from McBurney's point to the symmetrical of this point with relation to the median line of the abdomen. If there is perivisceritis of the right side, the sound is heard on the right, sometimes more loudly and sometimes longer than on the left side. The authors noted in ten cases the pain on raising the arms, and the bilateral sign of the tuning fork was positive in thirty-nine cases, but they point out that research by the last mentioned means is delicate. The physical signs have a secondary value, the advantage

remaining with the functional signs, which are strongly supported by radiologic examination. Of the physical signs, the most reliable and the most objective are those that utilize the transmission of sound vibrations through the abdominal viscera.

#### The Dictaphone and Competitive Examinations for Internships

The annual competitive examination to decide which medical students previously appointed, likewise on the basis of a competitive examination, to externships in the hospitals shall become interns, has never ceased, since its institution more than a hundred years ago, to provoke criticism. Those who fail to receive appointments are prone to charge the system with injustices. The committee of award is composed of hospital physicians and surgeons, who are chosen by lot. The members of the committee are frequently accused of favoring externs who have studied under them, with a view to recruiting a scientific entourage and strengthening their own particular "school." New means are therefore constantly being sought to prevent the judges from knowing the names of the candidates whose papers they examine. For the written portion of the examination the papers of the candidates are anonymous, being merely supplied with a number affixed by the administration, the owner of which remains unknown until after the papers are corrected. But for the oral portion of the examination the same method could not be applied. Mr. Mourier, director of the competitive examination, has discovered an ingenious solution. Each candidate will give to the dictaphone his replies to the oral questions, and from the wax records thus made disks will be prepared, which will reproduce, with the aid of a talking machine, the replies of the candidates in the presence of the judges. In this manner the identity of the candidates will be safeguarded. The cost of applying this method will be about 25,000 francs (\$1,500) for each examination.

#### Pericarotid Sympathectomy

Pericarotid sympathectomy, which was performed a few years ago by Mr. Leriche of Strasbourg, was regarded at first as a physiologic curiosity of experimental surgery. It produces a profound modification of the vascular action in the field of the sympathetic and in the area irrigated by the carotid artery. Mr. Magitot, in a communication to the Academy, has pointed out what good results can be secured with this operation in retinal disorders of spasmodic vasomotor origin and even in the progressive atrophies of the optic nerve. He reported six typical observations of persons who were gradually going blind, in whom this operation frankly checked the process and brought about a marked retrogression of the lesions thus far developed. The operation may be indicated also in other spasmodic vasomotor disorders affecting brain circulation. The operation is fairly simple, consisting in the decortication, for about 2 cm., of the nerve sheath of the common carotid; the decortication being continued up to the bulb of the internal carotid. In order to make the destruction of the nerve plexus more certain, the intervention ends with an application of isophenol.

#### The American Hospital (Neuilly)

Mr. Jesse I. Strauss, ambassador of the United States to France, paid an official visit to the American Hospital (Neuilly) to preside over the distribution of nurses' diplomas secured by the sixteen pupils who had completed the courses. Mr. Arthur T. Kemp, chairman of the administrative council of the school, explained to the ambassador that the diploma thus bestowed is highly appreciated, and that nurses who hold such a diploma easily find employment not only in the American Hospital but also in foreign countries. Dr. Georges M. Converse, head of the medical services, expressed regret that the school was obliged to close for lack of financial support which has been the fate of many other American undertakings in France since

the devaluation of the dollar has reduced by 40 per cent the value of the funds supplied from the United States. The departments of the American embassy in Paris have been able to retain their personnel only because they succeeded in bringing it about that, since June 1, their salaries and expense accounts have been paid in French money on the old basis.

#### Street Named in Honor of Dr. Carlos Finlay

The municipal council of Paris recently gave the name of Dr. Carlos Finlay to a street of the fifteenth ward of the capital, an honor to a foreign scientist almost without precedent, Humboldt and Linne being further examples. Finlay, whose mother was French, studied in France and on returning to his native country he announced the theory of transmission of yellow fever by mosquitoes. Last December the Academy of Medicine had celebrated the centenary of Finlay's birth at a special session attended by Professor Dominguez, who came to France to pronounce the eulogy of his compatriot.

#### Special Eugenics Courts

New legislation has provided special courts to determine what cases shall come within the application of the sterilization law. The reports of some of these courts are now available. The first session of a special eugenics court was held in Berlin on March 15. Up to May 30, twenty sessions had been held; in the meantime, a second chamber of the court has been organized. Within the period just mentioned, 348 court decisions were rendered, and in 325 cases sterilization of the person was ordered, while in the remaining twenty-three cases the request for sterilization was denied. In the 325 cases, the request came from the patients in 143 instances, seven times from the guardian, thirty-one times from the health officer, six times from the "court physician," and 138 times from directors of institutions. Table 1 shows the relative frequency of sterilization in males and females of various age groups.

TABLE 1—Relative Frequency of Sterilization in Males and Females

Age Groups	Males	Females
Under 20 years	5	8
20-29 years	80	66
30-39 years	69	50
40-49 years	27	9
Above 50 years	11	0
	192	133

Table 2 shows the condition that was the basis for sterilization.

TABLE 2—Basis for Sterilization

Hereditary Disorder	Number of Cases		Percentage of the Total
	Males	Females	
Congenital feeble-mindedness	52	44	29.6
Schizophrenia	59	53	34.4
Circular insanity	6	3	2.8
Hereditary epilepsy	51	29	24.6
Hereditary chorea (Huntington)	1	0	0.3
Hereditary blindness	0	0	0
Hereditary deafness	1	1	0.6
Grave hereditary bodily deformity	0	3	0.9
Alcoholism	22	0	6.8
Totals	192	133	100.0

It appears that congenital feeble-mindedness and schizophrenia comprised about one third of the cases.

The eugenics court in Kiel ordered 102 sterilizations during the months of March and April. An analysis of the fifty-five

sterilizations ordered in March, with respect to the basis justifying such intervention, is shown in table 3

TABLE 3—Analysis of Fifty-Five Sterilizations Ordered at Kiel in March 1934

Hereditary Disorder	Males	Females
Congenital feeble-mindedness	9	21
Schizophrenia	6	5
Epilepsy	4	6
Alcoholism	4	0

The Hamburg eugenics courts have received 1,325 applications for sterilization, a decision having been reached in 761 cases. Sterilization was refused in only seven cases. About 60 per cent of the cases concerned women.

### Eugenics in Relation to Deafness

The sterilization law necessitates a consideration of hereditary deafness, which is one of the notifiable hereditary disorders. For a long time it had been conjectured that deafmutism is hereditary. Hammerschlag has demonstrated that the movement of the Japanese dancing mouse, which is analogous to deafmutism, is transmitted, in accordance with the mendelian law, in the form of a monohybrid, recessive hereditary process. He concluded that the hereditary process of deafmutism in man might be the same. The hereditary disorders of the inner ear can be grouped together under the heading "heredopathia acustica." Hammerschlag differentiates (1) hereditodegenerative deafness (identical with constitutional sporadic deafmutism), (2) progressive labyrinthine hardness of hearing, (3) premature occupational hardness of hearing, and (4) otosclerosis. According to Hammerschlag, these disorders form a single unit from the standpoint of hereditary biology, which contention is denied by others, for example, Albrecht, who demonstrated that these various disorders present a diverse mode of hereditary transmission. Constitutional, sporadic deafmutism is transmitted in a monohybrid recessive manner, hereditary labyrinthine hardness of hearing being dominant. Concerning the hereditary type of otosclerosis nothing definite is known. Of these disorders, the law is concerned only with group 1, for the three other groups seldom lead to deafness, and even in the presence of high-grade hardness of hearing patients can be helped by prostheses, particularly in otosclerosis. In spite of its dominant hereditary process, hereditary hardness of hearing due to conditions existing in the inner ear seldom results in deafness in the offspring. There is difficulty in recognizing these cases. The classification into "congenital" or "acquired" cases is not fortunate, since likewise congenital deafmutism may be acquired in utero, for example, through syphilis, meningo-encephalitis or birth trauma. A better distinction would be "inherited" and "acquired" deafmutism. To the former would belong constitutional-sporadic and endemic deafmutism, usually associated with cretinism and idiocy, to the latter would belong the intra-uterine and the postfetal types, resulting from ear suppurations or infectious diseases. The diagnosis is easy if other hereditary stigmas are demonstrable, for example, retinitis pigmentosa, feeble-mindedness or cretinoid habitus. In the other cases the diagnosis can be made plausible only on the basis of researches on the family tree. Likewise the intact condition of the vestibular apparatus points to inherited deafness for the vestibular apparatus, as the phylogenically older organ, does not suffer so easily hereditary injuries as the younger cochlear apparatus. The question as to whether all deafmutes, on proof furnished that their condition is of a hereditary nature, should be sterilized will be negatived, yet it appears justifiable to incorporate hereditary deafness in the law. A conservative estimate places the number of hereditary deafmutes in Germany at about 13,000. This figure would indicate that some 1,500,000 persons are the bearers of the hereditary predisposition. New

patients will be found among the offspring if two persons with such a predisposition become mated. A careful choice of persons to be subjected to sterilization must be made. Obviously deafmutes with other hereditary disturbances of the central nervous system (idiocy, feeble-mindedness, and the like) will be considered first under the law. Importance attaches also to the sterilization of other deafmutes of hereditary origin who wish to enter on the marriage relation. That would be a big accomplishment, since 72 per cent of the deafmutes select life partners from their own group. In all other cases great caution must be exercised in making decisions. There are many highly intelligent deafmutes of hereditary origin who are far above the average of human stock.

### Meeting of the Society of Pathologists

The Deutsche Pathologische Gesellschaft convened in Rostock in May under the chairmanship of Hueck of Leipzig, who discussed the formation of metastases. Gliomas may occasionally develop metastases of the meninges but they do not occur outside the meninges, probably because they cannot break through the vessel walls. Henschen distinguishes glioblastomas, astroblastomas, astrocytomas, oligodendrocytomas, glioepitheliomas, choroido-epitheliomas, pinealomas, neuroblastomas and, as a special group, heteromorphous glioblastomas. The gliomas probably develop on a dysontogenic basis. While a traumatic origin may not be impossible, such a conclusion should not be reached without most careful consideration of all the facts.

Schmincke of Heidelberg, among others, pointed out that diffuse meningeal glioma formation is probably due to defects of development. Differentiation from meningeal sarcomas is difficult. These cases may easily be overlooked at operation. W. Müller of Berlin brought out that, during the period between operation and death, not infrequently a marked loss of differential features in the histologic structures of gliomas takes place. Pette of Hamburg emphasized that, from the neurologic standpoint, the clinician is interested, above all, in the question of malignity and cerebral tumefaction in association with gliomas. He is satisfied to divide gliomas into a benign and a malignant group. Malignant gliomas begin with a modification of personality without other demonstrable disturbances of functioning, whereas the onset of the benign type is marked by paralysis.

No further comprehensive papers were presented, but there were numerous other communications on certain details of the subjects. Henke of Breslau cautioned against considering all giant-cell sarcomas as epulis or osteitis fibrosa, for there are giant-cell tumors that occur in the tendon sheaths and the bones and that may be regarded as true sarcomas. Primary carcinoma of the pharyngeal tonsil is less rare than has been supposed. Graeff of Hamburg observed three cancers of the epipharynx among eleven pharyngeal cancers.

By research on the effects of exhaust gases of autos, Schmidt-mann of Cannstadt found that rabbits develop at first leukocytosis, which is followed by leukopenia and, if no relief is afforded, by death. Histologically the spleen shows the most marked changes. Similar changes were observable in workmen from the various industrial plants.

Research by Aschoff of Freiburg on the carotene content of human tissue demonstrated that cholesterol from atherosclerotic foci contains ten times as much carotene as ordinary fat, while the cholesterol of the suprarenals contains twenty times as much. In the liver, the carotene is changed to vitamin A, as can be demonstrated from the third fetal month on. In chronic nephritis, however, this transformation is disturbed. While the vitamin A disappears, the carotene content increases greatly. In cirrhosis of the liver, both values decline.

According to the research of Sjoëvall-Lund, the changes in the central nervous system in amaurotic idiocy do not have to

do with a secondary storage of lipoids but with an independent hereditary disturbance of the metabolism of these cells. As an expression of the premature aging of these brains, one may observe an extensive fibrogliosis.

Siegmund of Stuttgart was unable experimentally to produce pneumoconiosis in animals by means of inhalation. On the intravenous injection of pure quartz fibrosis developed only in the liver and not in the lungs. Evidently, fibrosis is produced only by quartz in a colloidal form. Similar conclusions were reached by Giese of Freiburg, who found tubercle like changes, such as cirrhosis of the liver and fibrosis of the spleen. His experiments led to no involvement of the lungs.

## NETHERLANDS

(From Our Regular Correspondent)

Aug 3, 1934

### Malaria in the Deltas of the Rhine and the Meuse

Malaria persists in the foci of North Holland, Friesland and the island of Walcheren. The foci that one encounters in South Holland, at the mouth of the Meuse and the Rhine, and also to the east of Groningen, at the mouth of the Ems, are even more important. The pathogenic agent is a particularly benign strain of *Plasmodium vivax*. The incubation period in dementia paralytica patients subjected to inoculation with this strain is three weeks (Korteweg). Attention is called to the long duration of the latent state of malaria, persons infected in September, October or December presenting ordinarily their first attack in April, July and August of the following year, after an interval of from seven to nine months. The majority of cases occurring in the Netherlands during the ordinary summer epidemic of malaria are due to infections contracted during the preceding autumn or winter. From April to the end of August, one finds practically no infected *Anopheles*. The secondary autumnal recrudescence of the frequency of malaria is doubtless due to exceptionally massive infections in which the ordinary period of latency is suppressed. Thus it can be understood why a high autumnal frequency of malaria may be the forerunner of an epidemic for the following year.

The deltas of the Rhine and the Meuse are not foci of malaria primarily because of the natural delta formation but because man has influenced their formation by the process of retrieving land, termed "poldering" the result of which is the transformation of harmless but useless salt-water lakes into rich soil areas traversed by ditches, which contain brackish waters, thus facilitating the propagation of *atroparvus* but this system of polders, or dikes which has engendered malaria in North Holland, has brought about its disappearance in South Holland, by substituting fresh water for the previous brackish waters, and thus replacing *atroparvus* with *messeae*. The hope appears reasonable, therefore that following the completion of the huge undertaking that has been launched in the Zuider Zee, and the transformation of the region that is not retrieved into a fresh-water lake one will witness the disappearance of *atroparvus* and consequently of malaria, and the predominance of the *messeae* variety. This system of retrieving land is, in principle, an antilarval campaign directed against *atroparvus*. If the undertaking succeeds the province of North Holland, the chief focus of malaria, will be the first to get rid of its brackish waters and of its fauna of *atroparvus*. Friesland, which has the second highest frequency of malaria, will also derive great advantages from the great hydrographic revolution that the new system will inaugurate. The foci of malaria in the provinces of Groningen and Zeeland will alone remain uninfluenced by the retrieving of lands in the Zuider Zee. But, in view of the unimportant role of these provinces in the malaria problem of the Netherlands, it is reasonable to hope that most of these foci will disappear, thanks to the measures designed to eliminate not all the *Anopheles* but solely

the fraction that, at the present time, is the cause of malaria. From this point of view, the immense project of retrieving the land occupied by the Zuider Zee may be regarded as a crusade against the carrier species of *Anopheles*.

### Inoculation of Tick-Bite Fever into Dementia Paralytica Patients

In the *Nederlandsch Tijdschrift voor Geneeskunde*, Pijper and Helene Dau give an account of their experiments carried on in Pretoria in treating dementia paralytica patients by inoculation with tick-bite fever. Tick-bite fever is a mild disease of the exanthematic typhus group, with a primary necrotic lesion. The virus may be preserved by passages through the guinea-pig, and such virus was used to inoculate patients having dementia paralytica. While the inoculation produced no therapeutic effect, the patients thus treated developed specific agglutinins, and in one case the virus was transferred from the patient to the guinea-pig without undergoing any apparent modification.

The mildness of the attacks confirms the fact that the virus of tick-bite fever and that of exanthematic typhus are not identical. The experiments brought out also that not all persons are susceptible to tick-bite fever. In persons who are not susceptible, the virus may circulate for two weeks.

### Drinking Water

The Royal Bureau of the Netherlands publishes in the *Verslagen en Mededeel. betr. de Volksgezondheid* a report on its recent activities in improving the drinking water of the whole country. The report gives a survey of the undertakings throughout the country, illustrated by maps and tables. It appears that the communes having their own system of water supply, which on Jan. 1, 1928, numbered about 400 out of 1,081, served a population of 4,600,000 out of a total of 7,500,000. By Jan. 1, 1933 this number had increased to 625 communes (out of 1,076), serving a population of 6,500,000 out of a total of 8,200,000. North Holland and South Holland are the provinces that have the largest percentage of water systems, serving respectively 99.6 and 99.16 per cent of the total population. The provinces of Gelderland and Drenthe have the lowest percentage, 52 and 26.6 per cent respectively. In some provinces a single company has a monopoly not only in a given city but also for the surrounding rural districts. The province of Drenthe is planning to combine its water system with that of Overijssel. Sometimes, for geographic reasons or otherwise, the organization is less centralized, but there is always a tendency to combine smaller systems into one large system. This tendency has its good and its bad features. Many difficulties result from the development of both national and foreign industries, which influence more and more the quality of the water in the rivers, from the greater utilization of dune areas, and from the increase in the amount of water consumed per person.

### Weil's Disease in the Dutch East Indies

The *Geneeskundige Tijdschrift voor Nederlandsch Indië* for Sept. 12, 1933, contains a communication of Dr. Mochtar on the frequency of Weil's disease in Celebes. The disease is rarely observed in Java, and in Batavia only three cases have been seen since 1925. No cases had been reported from Samarang up to 1932. The first case was observed in May 1932, since which time thirty-nine cases have been notified. Infection with *Spironema icterohaemorrhagiae* was suspected, and examination yielded nine cases with positive results. Of these nine cases, eight were reported from Samarang and one from Magelang. Two of these cases were fatal. In one of the two fatal cases, amebic dysentery was a complication. The clinical signs were the ordinary symptoms of Weil's disease. The mode of transmission of the disease to Samarang is

unknown. The large percentage of sewer rats that are carriers of the causative organism is an important factor not to be overlooked and leads to the belief that these rats play a part in the transmission of the disease.

Bezemer states that five cases of Weil's disease were observed between May 20 and June 1, two cases ending fatally. The mode of infection is not clear.

### CAPE TOWN

(From Our Regular Correspondent)

July 31, 1934

#### Payment of Hospital Staffs

During the last six months the profession has seriously considered and reconsidered its attitude toward the problem of the payment of hospital staffs. At the last meeting of the federal council of the association it was decided to leave to individual branches the decision whether or not to demand payment for services rendered to pauper patients in state supported hospitals. Briefly stated, the position in the Union of South Africa is as follows. There are no hospitals supported wholly by voluntary contributions; all hospitals are a charge on the taxpayer and to a lesser extent on the ratepayer, since the municipalities must make good the deficit under certain conditions. The expense of upkeep therefore falls on the doctor just as much as on any other class of taxpayer. But the provinces demand from the doctor free service for pauper patients and in addition mulct him in a yearly "license to practice" fee of £10. Under these circumstances the profession has decided that it will give voluntary service only where other classes of the community also give some voluntary service in teaching hospitals attached to the universities. But no uniform plan to enforce this decision has yet been formulated and in view of the divergence of local conditions and the difference of local views it may be quite impossible to agree on a uniform plan. In one province, Natal, most of the hospitals are already paying their honorary staffs; in a few hospitals in the Transvaal and the Free State the request for payment has been agreed to; in one hospital in the Cape Province payment is made. But the public does not yet understand why this request should be made, and much misunderstanding would be avoided if the profession would frankly disclose to the public what it today gives to the government in the shape of free service, time and experience. There is no reason whatever why the government should adhere to its licensing tax, the income derived from that source is a mere trickle toward the provincial treasury and the abolition of the tax which the doctors regard as iniquitous would to some extent meet the requirements of the profession for the recognition of the general principle that where the pauper is a charge on the taxpayer it is unfair to saddle one class of taxpayer with a disproportionate sum for his support.

#### The New Workmen's Compensation Act and the Medical Association

A measure of considerable interest to the profession was rushed through the last session of parliament and has attracted far less attention than its inherent importance deserves. This is the workmen's compensation act, an act which, thanks to the prompt action of the parliamentary committee of the medical association, is the first piece of legislation that makes definite provision for the treatment of private persons by the medical profession when such persons are injured in the course of their employment. The association, indeed, is actually referred to by name in the act itself in a remarkable clause which states that "the fees and charges for medical aid to workmen shall be in accordance with the scale prescribed by the minister from time to time after consultation with the Medical Association of South Africa, and no claim for an amount in excess of a

fee or charge in accordance with that scale shall lie against any workman or his employer in respect of any such medical aid." This is an advance in the right direction, and the profession is to be congratulated on it. The new act will complicate some matters, and it is unfortunate that the request of the committee of medical men to which the association referred it, that better provision might be made for accident cases admitted to hospitals, was not complied with. In labor circles there was unfortunately, a certain amount of opposition to the bill, caused partly by suspicion of the present government, which has not shown itself particularly friendly toward labor, and partly owing to a misunderstanding of the benefits under the act. Under the circumstances the profession must be satisfied with the benefits it has managed to secure.

#### Tick Bite Fever

There has for a long time been differences of opinion among pathologists in regard to several febrile diseases that belong apparently, to the Rickettsia group of typhus-like fevers. Pijper of Pretoria has now demonstrated that one of these febrile disturbances is a definite clinical entity, to which he has given the name tick bite fever. In recent papers Pijper has dealt with the clinical and serologic aspects of the disease. Tick bite fever is characterized by a primary lesion with a necrotic black center, the result of the infected tick bite, with secondary swelling of the infected lymph glands. The incubation period is eight days; it has an exanthem in the form of macules or maculopapules and is accompanied by severe headache and by a rise of temperature lasting ten days. The diagnosis is easy when one suspects it, and the prognosis is favorable; no fatal case has as yet been recorded. The Weil-Felix reaction is positive only in convalescence, and the disease gives perfect specific immunity. The treatment is symptomatic. In the Transvaal where the disease is common, old practitioners pin their faith to large doses of sodium salicylate, which have an immediate effect on the headache and joint pains. The disease has nothing in common with tick fever. Its virus has characteristics that completely differentiate it from that of a mild typhus. Arsphenamine as a remedy is useless.

#### Medical Service for Natives

The neglect of the native territories so far as education and medical service are concerned has been a blot on the administration of the various governments since the union was established. Public opinion has now forced the present government, which is in many ways especially where health questions are concerned behind its predecessor, to make an attempt to deal with one phase of the problem of medical aid to natives. In the protectorates too the matter is now receiving attention. The scheme of the protectorates provides for a common sense course for medical aids much on the lines that have been developed in Java. That of the union government is more ambitious and may lead to the creation of a class of second grade general practitioners practicing in the native territories only. A definite promise has been made however that the scheme will not be enforced before the medical association has had an opportunity to express its opinion on the details.

#### Deaths

Dr. Charles Porter, formerly medical officer of health for Johannesburg, has died of coronary thrombosis. He was a forceful personality, a barrister as well as a doctor, and one of the pioneers of child welfare work.

Dr. P. de V. Moll died this month as the result of a motor accident. He was one of the younger specialists and lecturer on orthopedics at the University of Cape Town.

Dr. D. M. Tomory, formerly medical officer of health for Bloemfontein and Dr. A. C. Seale, formerly superintendent of the New Somerset Hospital, Cape Town, died last month.

## Marriages

HELSMEL CLANTON LENNON, Wilmington, N C, to Miss Myrtle Catherine Hendley of Ansonville, at Durham, June 16

FERN WARD BUOBA Des Moines, Iowa, to Miss Neoma Kistenmacher of Davenport, at Chicago, August 27

DAWSON EDWARD WATKINS JR, Waynesboro, Va, to Miss Mary Evelyn Stephenson of Buena Vista, June 23

JAMES WAITON LIPSCOMB JR, Columbus, Miss, to Miss Anne Elizabeth Dubard of Grenada, June 6

LAURIE WALKER MOORE Beaufort, N C, to Miss Anne Pryor Neale of Lanesville, Va, June 2

THOMAS ALLEN LACY, Brantwood N Y, to Miss Cornelia Archer of Montreat, N C, June 30

ROGERS NEWTON HARRIS Port Royal Va to Miss Mary McLaughlin of Lynchburg May 19

CHARLES DUFFY, New Bern N C, to Miss Mary Pickett Breck of Maysville, Ky April 17

CHARLES W LAWRENCE, Emporia Kan, to Mrs W O Thompson of Dodge City, July 2

RUDOLPH ANGUS NICHOLS JR to Miss Elizabeth Williams, both of Richmond, Va, June 1

CARL C CARRICO, Houston Texas, to Miss Helen M Murphy of Denison, August 4

JULIUS CLEON JOSEY to Miss Mary Helen Lancaster both of Spartanburg, S C, June 9

RODALL MARY CALDER to Miss Laurie May booth both of Durham, N C, August 18

EDWARD WILLIAM SACHS to Miss Mary Clare Smith, both of Dayton Ohio August 29

JOHN LATZO, Wilmington, Del to Miss Agnes Rynkiewicz of Tamaqua, Pa recently

ULIS B HINE, Indianapolis, to Miss Geraldine Jeffries of Newcastle Ind, June 24

JAMES MORRIS PFEIFER, Lawrenceburg, Ind, to Miss Alice Helen Mueller, June 23

WILLIAM BEVERLEY WILKINS Alexandria, Va, to Miss Gladys Nichols, June 2

ARCHER CHARLES BACHMEYER, Cincinnati to Miss Mary Hicks, recently

## Deaths

Augustus Ravogli, Cincinnati Regia Università di Roma degli studi Facoltà di Medicina e Chirurgia, Italy, 1873, chairman of the Section on Dermatology and Syphilology of the American Medical Association, 1896-1897 member and past president of the American Dermatological Association, member of the American Urological Association, fellow of the American College of Surgeons, for many years member and past president of the Ohio State Medical Board past president of the Cincinnati Academy of Medicine professor emeritus of dermatology and syphilology, University of Cincinnati College of Medicine formerly on the staff of the Cincinnati General Hospital, author of Syphilis in Its Medical Medicolegal and Sociological Aspects aged 83 died, July 25, in the Deaconess Hospital, of cerebral hemorrhage arteriosclerosis and chronic nephritis

Samuel Kemp Merrick, Ruxton Md University of Maryland School of Medicine, Baltimore, 1872 member of the Medical and Surgical Faculty of Maryland, fellow of the American College of Surgeons professor emeritus of rhinology and laryngology at his alma mater, past president of the Baltimore City Medical Society, member of the Board of Regents of the University of Maryland for many years on the staff of the Maryland General Hospital Baltimore, aged 86 died, July 24 of heart disease.

Peter W Tomlinson of Wilmington, Del, Jefferson Medical College of Philadelphia, 1878, member of the House of Delegates of the American Medical Association, 1907-1908 in 1919 in 1926 and in 1931 past president secretary and councilor of the Medical Society of Delaware past president of the board of medical examiners, consulting medical director of the Continental American Life Insurance Company aged 84, died July 25 in the Beebe Hospital, Lewes of pneumonia

Henry Louis Stick of Canandaigua N Y College of Physicians and Surgeons Baltimore 1900 member of the

Medical Society of the State of Pennsylvania, the American Psychiatric Association and the New England Society of Psychiatry, served during the World War, aged 61, on the staff of the Veterans' Administration Facility, where he died suddenly, August 15, of cerebral hemorrhage

Albert Winslow Horr of Boston, Boston University School of Medicine, 1891, emeritus professor of ophthalmology at his alma mater member of the New England Ophthalmological Society, fellow of the American College of Surgeons consulting ophthalmic surgeon to the Massachusetts Memorial Hospitals, aged 69, died, August 3, of angina pectoris, at Watertown, N Y

James Spencer Brown, Pinchurst N C, College of Physicians and Surgeons, Medical Department of Columbia College 1885, served during the World War, for many years on the staff of the Mountainside Hospital, Montclair N J, fellow of the American College of Surgeons aged 71, died, August 18, at his summer home in Malletts Bay, Vt, of pneumonia

Frederick Ernest Wilcox of Willimantic, Conn, New York Homeopathic Medical College, 1884, member of the Connecticut Homeopathic Medical Examining Board past president of the Windham County Medical Society on the staff of the Windham Community Memorial Hospital, aged 74 died, August 8, of uremia and pyelonephritis

Goode Cheatham, Henderson, N C North Carolina Medical College, Davidson, 1895, past president of the Vance County Medical Society, formerly county health officer, past president of the Association of Seaboard Railway Surgeons aged 59, died suddenly, August 3, of coronary thrombosis, at the home of his son in Endicott, N Y

Merchant William Colgin, Waco, Texas, Vanderbilt University School of Medicine, Nashville, Tenn, 1905 member of the State Medical Association of Texas fellow of the American College of Physicians, past president of the McLennan County Medical Society, part owner of the Colgin Hospital and Clinic aged 51, died, July 15

Lyle Joseph Willis, Fort Madison, Iowa, University of Illinois College of Medicine, Chicago 1929, member of the Iowa State Medical Society medical superintendent of the Atchison, Topeka and Santa Fe Railway Hospital, aged 33, was killed August 11 when a gun he was cleaning was accidentally discharged

Lawrence Rosboro Craig, Franklin, La, Medical College of Virginia, Richmond, 1906, served during the World War, director of St Mary Parish Health Unit, aged 52, died, August 5 in the Army and Navy General Hospital, Hot Springs National Park, Ark, following a fracture of the fourth dorsal vertebra

Arthur Mitchell, Medfield, Mass, Boston University School of Medicine, 1886, member of the Massachusetts Medical Society, formerly on the staffs of the Framingham (Mass) Union Hospital and the Leonard Morse Memorial Hospital, Natick aged 70, died, July 24, in the Corey Hill Hospital, Brookline

Nathaniel Thackery Stevens of Clifton, Ill, Queen's University Faculty of Medicine Kingston Ont Canada, 1892, past president of the Kankakee County Medical Society, on the staff of St Mary Hospital, Kankakee, aged 70, died, July 26, at the North Shore Health Resort, Winnetka

Gurney Claycomb Wallace, Denver, Denver and Gross College of Medicine, 1906 member of the Colorado State Medical Society, veteran of the Spanish-American War, formerly demonstrator of anatomy at his alma mater, on the staff of the Presbyterian Hospital, aged 56, died, July 7

Benjamin H Blair of Lebanon Ohio, Louisville (Ky) Medical College 1876, member of the House of Delegates of the American Medical Association, 1910-1911 county health officer for many years member and president of the board of education, aged 79, died August 15, of heart disease

Charles E Wilkerson, Greensboro, N C University of Nashville (Tenn) Medical Department, 1907 member of the Medical Society of the State of North Carolina formerly a medical missionary on the staffs of the Clinic Hospital and the Wesley Long Hospital, aged 55 died, July 13

Jean Beatrice Christie, Newberry Mich Woman's Medical College of Pennsylvania, Philadelphia, 1912, member of the Michigan State Medical Society for many years on the staff of the Newberry State Hospital, aged 55, died, July 23, of chronic myocarditis and arteriosclerosis

Ralph Salem Heilman, Sharon Pa University of Pennsylvania School of Medicine, Philadelphia, 1907, member of the Medical Society of the State of Pennsylvania served during

the World War, medical director of the Protected Home Circle, aged 54, died, July 19

**Roy A Windham** ♂ Port Huron, Mich., Detroit College of Medicine, 1912, past president of St Clair County Medical Society, on the staff of the Port Huron Hospital, aged 55, died, July 18, of arteriosclerosis and coronary and cerebral thrombosis

**David Phipps Rettew**, Coatesville, Pa., University of Pennsylvania School of Medicine, Philadelphia, 1890, member of the Medical Society of the State of Pennsylvania, aged 68, died, July 11, in the Pennsylvania Hospital, Philadelphia

**George A Whitledge** ♂ Anderson, Ind., University of Louisville (Ky.) School of Medicine, 1891, fellow of the American College of Surgeons, aged 65, on the staff of St John's Hospital, where he died, July 4, of heart disease

**Ralph Waldo Holbrook** ♂ Kansas City, Mo., Kansas City Medical College, 1904, past president of the Jackson County Medical Society, aged 54, on the staff of the Research Hospital, where he died, August 22, of heat prostration

**Robert Wesley Hallenberg** ♂ Bismarck, N. D., University of Illinois College of Medicine, Chicago, 1932, on the staff of St Alexius Hospital, aged 29, died, August 1, of skull fracture received in an automobile accident

**William Joseph Siegler** ♂ Chicago, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1910, on the staff of the Evangelical Hospital, aged 59, died, August 17, of angina pectoris

**John William Nelson**, Jamestown, N. Y., Columbia University College of Physicians and Surgeons, New York, 1896, aged 67, died, in June, as the result of a severed artery in his thigh, self inflicted with a piece of glass

**Francis Thomas Ridley**, Bluefield, W. Va., University of Virginia Department of Medicine, Charlottesville, 1903, member of the West Virginia State Medical Association and the Medical Society of Virginia, died, July 19

**Samuel Lowery Adair Jr.**, Jeffersonville, Ind., Kentucky University Medical Department, Louisville, 1904, city health officer and formerly county health officer, aged 54, died August 2, of a self inflicted bullet wound

**Trusten Mitchell Hart** ♂ Los Angeles, University of California Medical Department, Los Angeles, 1911, on the staff of the Los Angeles County General Hospital, aged 53, died suddenly, July 14, of heart disease

**Carl Friedrich Wolff**, New York, Bellevue Hospital Medical College, New York, 1885, aged 70, died, August 7, in the Southampton (N. Y.) Hospital, of a skull fracture received in an automobile accident

**Simeon Gould Start**, Cambridge, Vt., Bellevue Hospital Medical College, New York, 1895, member of the Vermont State Medical Society, aged 64, died, June 20, in the Fanny Allen Hospital, Winooski

**Eugene Eliel Brunson**, Ganges, Mich., Bennett College of Eclectic Medicine and Surgery, Chicago, 1875, past president of the Ottawa County Medical Society, aged 82, died, August 5, of pneumonia

**George Russell Beck**, Detroit, University of Michigan Medical School, Ann Arbor, 1926, aged 31, was drowned August 11, in Northport Bay when the sailboat in which he was riding capsized

**Cyrus A Kirkley**, Los Angeles, Starling Medical College, Columbus, 1868, member of the Ohio State Medical Association, fellow of the American College of Surgeons, aged 89, died, July 27

**Thomas G Cooksey**, Converse, S. C., Louisville (Ky.) Medical College, 1890, member of the South Carolina Medical Association, aged 68, died, July 17, in a hospital at Spartanburg

**Duncan McEdwards**, Hamilton, Ont., Canada, Trinity Medical College, Toronto, 1886, aged 73, died, April 26

**David H Yates**, Madison, Fla., Atlanta Medical College, 1894, aged 68, died, June 21, of Raynaud's disease

**Donald McLeod**, Toronto, Ont., Canada, Trinity Medical College, Toronto, 1890, aged 67, died, April 19

## Correspondence

### POPULAR HEALTH EDUCATION

To the Editor—Driven by a constant bombardment of ridiculous references by patients to library books, I undertook to investigate the popular medical volumes on the shelves at the Springfield Public Library. The result of the investigation was astounding. Most of the books were either so antiquated as to beg retirement or else bore such ignorant, preposterous or downright quack authorship as to make one exclaim with horror. The biggest shock, however, came when in response to a call for assistance, one of the librarians suggested the late Alfred McCann's "The Science of Eating" as a very good book on diets. That McCann (see THE JOURNAL, June 20, 1925, and March 15, 1930) should have created such a piece of quackery is only natural, but that a city library would circularize and even recommend it to its citizenry was rather hard to understand.

An effort to present this unsatisfactory state of affairs before the local library authorities as well as to the public in the form of an open letter to the Springfield *Republican* so far has brought no results.

It is high time that the profession took steps to remedy this perplexing situation. The creation of a committee of experts for the evaluation of popular medical books is to be hailed as a step in the right direction.

MAN MILLMAN, M.D., Springfield, Mass.

### WORKMEN'S COMPENSATION ACTS AND PHYSICIANS' FEES

To the Editor—On July 3, 1934, there ended in the Circuit Court of [Cook County] Illinois a case which will be instructive to all doctors who take care of the occasional case of an employee injured while at his work.

In 1930 one of my regular patients came to me with a hand infection produced by an injury occurring during his work. I treated him. The last time was about forty days after the injury. A week after he first consulted me the Continental Casualty Company sent me a blank form asking for a report on his injury, which I filled out and returned to them. The same was done with one or two later report blanks.

After the patient was well I sent him a bill for services, making my regular charges to him as to any of my other patients. A few days later I received a letter from the insurance company asking for an itemized bill, which I sent them. Later I received a check from the insurance company for about 50 per cent of my bill and a letter saying that the check was in conformity to fees they were regularly paying to other doctors. I returned the check with a letter saying that the fees charged were my regular fees which I expected to be paid that I did not allow any one else to determine the value of my services, and that I did not do enough work for them to justify giving them a special price or discount.

Later I received from them a letter saying that my charges "were not in conformity with the usual and customary rates and were considerably more than the amount designated by the Industrial Commission of this state which has jurisdiction over such matters." They tried to deceive me into believing that the Industrial Commission had established a fee schedule.

I replied that the Industrial Commission had no jurisdiction over my fees to my private patients. Later I sued the patient for the bill in a justice court and got a judgment, though the insurance company lawyer represented him and tried to persuade the justice that the Industrial Commission had set certain fees. He then appealed the case and the appeal recently came to trial with the result that my bill was allowed.

The Chicago Medical Society furnished an attorney to represent me at both trials with the hope of establishing a precedent against these "chiseling" insurance companies. The society has now won two other such cases.

Let me state just what this case determines for you.

1 You can collect your regular fees in cases of industrial accidents if you have not made any agreement as to fees with the employer or the insurance company.

2 The Industrial Commission or even the state of Illinois cannot set your fees. If there is a dispute the court or perhaps the Industrial Commission, in case of workman's compensation, may pass on reasonableness of the fees.

3 Don't let the insurance company "bluff" you out of your regular fees if you have made no definite agreement with them.

4 The Chicago Medical Society is working to protect your financial interests.

LESLIE W. BEEBE, M.D., Oak Park, Ill.

[COMMENT—The following comment is offered by the Bureau of Legal Medicine and Legislation—Ed.]

The workmen's compensation acts of the several states are not uniform. Some of them probably contain provisions differing in detail from those to be stated. What is here stated, however, is believed to represent the prevailing rule.

Workmen's compensation acts do not regulate contracts of physicians with injured workmen whom they treat, or with the employers of such workmen, or with the insurance carriers of such employers. They go no further in this connection than to authorize workmen's compensation boards to award, within statutory limits, to an injured workman, among other items, a sum theoretically sufficient to reimburse him for money which he has paid or has obligated himself to pay for medical services that his employer wrongfully failed to provide.

An employer or an insurance carrier that requests a physician to attend an injured workman, without agreeing on a stated amount to be paid for his services, is liable in an action at law for the reasonable value of such services, to be determined by the court.<sup>1</sup> Workmen's compensation boards have nothing to do with the fees that a physician collects under his contracts with employees, employers and insurance carriers. As a matter of fact, workmen's compensation acts do not provide methods by which physicians can on their own initiative recover their fees for such services, although if an injured workman files a claim for compensation that includes the amount he has paid or is obligated to pay for medical service the physician by filing his claim against the workman may in some states establish what amounts to a lien on any award in the workman's favor. The physician must have recourse to the courts and the ordinary processes of law,<sup>2</sup> if he would establish his claim directly against an employer or an insurance carrier.

An injured workman who requests a physician to attend him is personally liable, in the absence of an express or implied agreement to the contrary, for the reasonable value of the physician's services. An award made by a workmen's compensation board in favor of the workman and against his employer does not limit the amount the physician can recover from the workman in an action at law.<sup>3</sup> A physician may, however, bind himself by an express or implied contract to accept whatever amount the board awards the workman. If, for instance, a physician has customarily demanded of injured workmen whom he has treated fees equal to the amounts awarded to such workmen by the workmen's compensation board for medical service, a court may reasonably conclude that the physician always limits his fees in such cases in that manner.

<sup>1</sup> 72 American Law Reports 1016 and cases there cited. Knox v. Stove Works v. Hodge (Tenn.) 289 S. W. 505.

<sup>2</sup> Wilson Drilling Co. v. Beyer (Okla.) 280 P. 846. Robinson v. Taylor (Okla.) 244 P. 47. Bloom v. Jaffe (N. Y.) 94 Misc. 222. 157 N. Y. S. 926.

<sup>3</sup> Noer v. Jones Lumber Co. (Wis.) 175 N. W. 784.

and that the workman entered into his contract for medical services in reliance on the physician's custom. Moreover, if in any particular community the entire medical profession customarily accepts in satisfaction of all charges for medical service rendered injured workmen the amounts awarded to such workmen for medical service by the workmen's compensation board, that custom, in the absence of an express or implied agreement to the contrary, may operate to limit the amount that the court will award a physician. In any case, the court will endeavor to ascertain the true intent of the physician, the employer, the insurance carrier and the workman when an agreement or contract for medical service is entered into and will see that the agreement or contract is enforced in a manner that accomplishes that intent.

## Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

### THYMIC DEATH

*To the Editor*—A multipara with a markedly contracted pelvis gave a history of two previous deliveries with high forceps, one child dying at birth and the other twenty-four hours later. The second was blue and never cried lustily and was given oxygen and stimulants to no avail. In view of the history and a markedly contracted pelvis I did a cesarean section April 17 at full term. This child had the same appearance of the preceding one. After one hour the color was good and a few breath sounds could be heard. Oxygen and carbon dioxide were given for ten hours with a catheter inserted but the child died. From the history I believe that all three possibly died because of an enlarged thymus. This child post mortem was normal except for a markedly enlarged thymus much firmer in consistency than normal. The lungs were completely atelectatic except in the upper lobes. With this history could any prenatal plan of treatment be instituted to guard against this again? Is it common for a mother to have more than one child with an enlarged thymus? Physical examination and blood tests on the mother, child and father were negative except as given for the child. Would you let me know what can be found in the literature as soon as possible for report at our hospital staff meeting? Please omit name if published.

M. D. Washington

*ANSWER*—There is a form of sudden death in newborn infants which has been designated by the term "thymic death." This term does not indicate a mode of death by suffocation, coming on after symptoms of obstruction. It is rather a totally unexpected death by asphyxia which occurs in infants immediately after birth, a few hours later or, more rarely, during the first few days. If the case is an early one the infant may be quite healthy and show no signs of respiratory embarrassment. If late, the infant may have already manifested some stridor, and death occurs during a sudden exacerbation. Two explanations are commonly offered to account for the role of the thymus in the causation of sudden death during this period. The gland possibly presses against the trachea and large vessels and thus mechanically causes suffocation and death, or death may be the result of status thymicolymphaticus, an anomaly of the constitution which is held responsible for sudden and unexpected deaths of apparently healthy individuals later in life. Most authorities consider that "thymic death" in newborn infants is to be explained on the mechanical theory. If the infant dies shortly after birth, before complete recovery from asphyxia of the labor, it cannot be assumed that the thymus was the one and only cause unless there is anatomic proof of the enlargement of the gland and of its pressure on the trachea and the large blood vessels. Such cases have been described in the literature but there have been no reports occurring in successive members of the same family. As early as 1906 Hedinger reported the deaths shortly after birth, with signs of asphyxia, of seventeen apparently healthy infants. In all these cases, necropsy revealed a more or less pronounced hypertrophy of the thymus, but enlargement of the thymus without symptoms occurring in more than one member of the same family is not uncommon. The incidence of an enlarged thymus in the newborn varies with the type of infant. For example, infants with congenital defects and malformation have an incidence of over 30 per cent.

Lately there has been some doubt in regard to the causal relationship of an enlarged thymus to sudden death. That the question of sudden death in infants is a more complex one than

can be simply explained by a local cause is indicated not only by presumption of an associated morbid diathesis, status thymicolymphaticus, but also by the association of other constitutional deviations and endocrine defects. Cases of sudden death are recorded in which the necropsy fails to reveal the slightest enlargement of the thymus, and even when a large thymus is found with symptoms of tracheal compression, the actual cause of death may be something quite different. One can only recognize that the thymus may produce signs of obstruction and that this may be the cause of death in some cases. There is no scientific basis, however, for asserting that the thymus is the cause of sudden death by asphyxia which occurs immediately after birth or within the first few days unless it can actually be shown that the thymus produced obstruction. G. I. Still (*Lancet* 1 431 [March 3] 1923) called attention to five cases showing sudden arrest of respiration immediately after birth and days later in infants apparently healthy. No cause was definitely decided on. A little later Cruickshank called attention to the pressure of the contracting uterine walls on the infant as one of the causes for asphyxial congestion. He is of the opinion that asphyxial congestion is the most usual factor in producing hemorrhage. Such hemorrhage may be in the nature of tiny hemorrhages in the pons. Kirkwood, Myers and Lumsden (*Lancet* 2 65 [July 14] 1923) believe that hemorrhage into the pons is doubtless an unrecognized cause of death in newborn infants with inspiratory apnea. Cerebral hemorrhage, atelectasis, congenital debility and supranatal changes are other causative factors for sudden death in the newborn period which should not be overlooked even in the presence of an enlarged thymus.

In the present state of knowledge there is no effective prenatal treatment to guard against an enlarged thymus in the newborn infant. Irrespective of one's conception of how symptoms are produced the value of roentgen therapy for enlargement of the thymus during the neonatal period, however, is tangible.

### LOSS OF HAIR

*To the Editor*—Can you tell me what possible deficiency might exist in the case of a patient who has progressive loss of hair, with absence of any known disease and a scalp that has no appearance of being diseased? If you cannot give me this information can you tell me where I can get it?

M. D. Conn

*ANSWER*—Progressive loss of hair (alopecia) may be seen as senile alopecia occurring most frequently in men and developing in advancing years. It is thought in some instances to be a result of the cutaneous atrophic changes associated with old age. Since the loss of hair in these cases is usually on the vertex and above the forehead where pressure of the aponeurosis of the occipitofrontalis muscle is greatest this is thought to be a factor. A mild seborrhea, so slight as to escape notice, undoubtedly exists in many cases. Premature baldness (alopecia prematura) is divided etiologically into idiopathic and symptomatic. Idiopathic alopecia is in many instances hereditary, and the stretched condition of the aponeurosis of the occipitofrontalis muscle, which becomes hereditary in certain families, is stressed by Pincus as a factor. He also states that a chronic eczema or impetiginous eruption of the scalp in the years preceding puberty, is a more frequent cause, and that it is often associated with symptoms of relative or absolute debility. Because of the prevalence of this type of baldness in those leading sedentary lives and in brain workers, Jamieson advances the theory that the nerves supplying the scalp are in direct connection with those supplying the coverings of the brain and that an irritable condition of the brain due to cerebral congestion would reflexly interfere with hair growth. Compression of the anterior temporal arteries by stiff hats, which also excludes sunlight and air, have been assigned as causes. Undue exposures to the rays of the sun without head covering is given significance by Harding. Lack of care of the hair and excessive use of water are also considered factors.

The symptomatic variety of premature alopecia has a recognizable cause, which differs widely in each case. The hair loss may result from general or local disease of the scalp or body. It may occur after fevers or severe acute systemic disease (defluvium capillorum) when it is rapid, or the hair loss may be slow as in alopecia pityrioides, in which seborrhea is a factor, and this is probably the most frequent local cause of alopecia.

Conditions affecting the patient generally, such as anemia, anxiety and worry, dyspepsia, rheumatism, malaria, the menopause and neurotic disturbances, are cited as predisposing causes by Jackson and McMurtry (*Diseases of the Hair*, Philadelphia, Lea & Febiger, 1912). Endocrine factors related

to deficiencies of the anterior pituitary gland (Bengtson, B N Pituitary Therapy of Alopecia, *THE JOURNAL*, Nov 7, 1931, p 1355) have received attention as causal factors. The role of the thyroid in the alopecias has also been stressed. While endocrine therapy has given results in individual cases, these results on the whole have been variable and inconclusive. The toxic action of certain drugs, such as thallium and arsenic, in the production of baldness must be considered, and the possible contributory factors of these drugs should be ruled out in every case.

The role of sulphur in alopecia has recently been reviewed by Brown and Klauder (Sulphur Content of Hair and of Nails in Abnormal States, *Arch Dermat & Syph* 27 584 [April 1933]). They feel that the metabolism of sulphur is only one phase of the mechanism of the growth and loss of hair and state that "this mechanism apparently involves an interplay of other factors, notably the endocrine glands and the sympathetic nervous system."

#### HEMATOMA AFTER EXTRACTION OF TOOTH

To the Editor—A woman aged 25 had the upper left first molar extracted under local anesthesia (procaine hydrochloride) one year ago. This extraction was followed by swelling over the left zygomatic bone and infra-orbital region the following day. This region became discolored (ecchymotic) about seven days later. The discoloration and swelling varied in amount and intensity throughout the next ten months associated with considerable pain. The condition had improved to some extent at the end of that time. One month ago (ten months after the first extraction) the upper right first molar was extracted under local anesthesia. This was followed by swelling and discoloration over the right zygomatic bone and infra-orbital region the next day. This condition accompanied by considerable pain has persisted up to the present time. Neither extraction was followed by loss of more than a few drops of blood. Seven years ago the patient suffered a nervous breakdown. Thyroidectomy was performed without improvement in the symptoms according to her statement. For two or three years following this operation she was treated in nervous and mental institutions. She has been under home treatment for the past three years. She is still extremely nervous and starts crying at slight provocation. She has had four other molars extracted under local anesthesia during the past few years with out untoward results. The Wassermann reaction is negative. There is no history of purpura. The left side of the face is still improving. Physical examination is essentially negative except for the condition noted and extreme nervousness. Roentgen examination seven months after the extraction of the upper left first molar revealed no infection or bone injury at the site of the extraction. Laboratory and other examinations one month before the second extraction revealed red blood cells 5,010,000 white blood cells 10,200, hemoglobin 95 per cent, polymorphonuclears 48 per cent, lymphocytes 52 per cent, clotting time two minutes. Urinalysis was negative for albumin, sugar and pus. The specific gravity was 1.018. The blood pressure was 120 systolic, 80 diastolic, pulse 100, temperature 98. I feel that this condition is due to repeated self-inflicted trauma arising from a desire for sympathy. Could there be a pathologic cause for this condition? Kindly omit name and address if this is published. MD Virginia

ANSWER—Hematoma following the extraction of teeth under local anesthesia is not uncommon. Sometimes the swelling and discoloration appear immediately even before the hypodermic needle is removed. More commonly it occurs a number of hours later or on the following day. In rare instances it is recurrent, lasting for a few weeks but the condition recurring over ten months has not been observed. We know of no other condition that could produce the symptoms described.

#### BRACHIAL PLEXUS INJURY DURING BIRTH

To the Editor—A baby delivered with considerable difficulty by breech extraction some ten days ago appears to have an upper arm paralysis on the left side. For the first two days it was observed that the infant moved only its fingers. Gradually movements of the wrist and forearm have appeared but so far no movements of the upper part of the arm have been observed. The arm assumes a position of inward rotation with the thumb pointing backward. Apparently the paralysis involves the deltoid, infraspinatus and supraspinatus muscles which constitutes I believe the Erb-Duchenne type of paralysis. What is the prognosis of this type of injury? Can anything be done to restore function? Is there any particular position in which the arm should be placed and held? Please omit name. MD Wisconsin

ANSWER—The clinical picture of a baby which has not moved its arm from the time of birth but with gradual increase of the movements of the fingers, wrist and forearm suggests at once a brachial plexus injury which probably resulted from overstretching the nerves of the brachial plexus during the delivery of the aftercoming head. Such paralysis may involve almost wholly the nerves supplying the muscles by which the arm is moved at the shoulder and constitutes the typical Erb-Duchenne syndrome.

When the hand and wrist muscles are involved and not the shoulder the injury is usually due to traction on the arm in a breech delivery. The eighth cervical root and the first thoracic nerve roots are involved in this Klumpke paralysis.

Usually, however, the paralysis is of the whole arm type but more severe in the upper or lower part of the arm, as the case may be.

The treatment should be one of protection through splinting with the arm held in a strap hanger or airplane splint which maintains 90 degrees abduction and, as nearly as possible, complete external rotation. If the hand is involved, the upright part of the splint should have a flat surface at the side of the hand to which the fingers should be strapped in the extended position. This splint should be worn for twenty-four hours a day for several days and should be removed only for bathing the baby. After one week it is advisable to remove the splint for one hour each morning during which the arm is allowed to rest at the infant's side and the shoulder and arm may be gently massaged. After two weeks the splint should be removed for one hour both morning and afternoon and each time the arm should be massaged for about fifteen minutes. If the recovery of the muscles has been quite definite, it will then be safe to leave the splint off for two hours morning and afternoon and permit the infant to use the arm as much as possible during that interval. The length of time which the splint is removed should be increased at the rate of an hour a week until it is left off all day after from three to four months. If there is still weakness at this time in the shoulder muscle group, it is advisable to continue wearing the splint at night for as long as a year or until such time as a normal range of active shoulder motion is definitely established. This splinting relaxes the tension on the brachial plexus and also prevents contractures of muscles or ligaments about the shoulder.

The prognosis for about 70 to 80 per cent recovery in most of these cases is good. Occasionally these infants seen during the first few days after delivery with apparently total whole arm paralysis make so nearly a complete recovery that an examiner cannot detect any weakness when the patient is 1 year of age.

#### NUPERCAINE AND TOXICITY OF LOCAL ANESTHETICS

To the Editor—There are hospitalized at this facility about 1700 patients. Almost every conceivable type of disease is to be found at one time or another among this large group of patients. From time to time attention is called to new anesthetics both local and general. We have no desire to be the last to try out new remedies but on account of the nature of our work and the fact that this is more or less a public institution we must maintain a certain amount of conservatism in the use of new anesthetics. Nupercaine (Ciba) is one of the newer local anesthetics and from the description given in New and Nonofficial Remedies, one is led to believe that it possesses a high degree of toxicity. A great deal of local anesthesia is used in our genito-urinary department, eye, ear, nose and throat department, cancer service and in some cases of tuberculous ulcers of the larynx. If nupercaine may be used generally with safety, we are anxious to give it a trial. However before attempting its use extensively a few questions should be answered satisfactorily. 1 May this local anesthetic be injected into the larynx in a 2 per cent solution? If not what percentage should be considered as the limit of safety? Also what quantity should be used? This question is prompted by the fact that in your description you mention that cases have been reported in which it caused necrosis of the tissue. 2 May a 2 per cent solution be injected into the urethra? If so in what quantity? 3 May this solution be used in eye work? Is there any danger of necrosis when used in this manner? If nupercaine has proved to be more than ordinarily toxic, we should like to know and we shall not adopt it as a local anesthetic. W E KENDALL, M D, Hines III

ANSWER—When one is warned that a given local anesthetic is highly toxic, one is prone to forget that the toxicity of a substance may be actually high but may be relatively low, and it is the relative toxicity of an active substance that determines the safety with which it may be used by one who understands its possibilities and limitations. It is the accepted policy of the Council on Pharmacy and Chemistry not to accept a new local anesthetic merely because it is capable of inducing anesthesia, and before accepting a new substance of this class for New and Nonofficial Remedies the Council demands evidence that it possesses some advantage over other well known local anesthetics.

The important thing to be borne in mind constantly when one uses any local anesthetic for any purpose is to use the smallest amount and the lowest concentration that are effective. The Committee for the Study of the Toxic Effects of Local Anesthetics (*THE JOURNAL*, March 15, 1924) concluded that the local anesthetics may be used safely if the conditions laid down in the report are observed.

It is well known that, gram for gram, nupercaine is more toxic than procaine but it is also more active in inducing local anesthesia, consequently, much less of it is required. It has the advantage that the anesthesia induced usually lasts for from two to three hours or even longer, whereas the anesthesia induced by procaine usually does not last more than two hours and often less than that. It is plain, therefore, that a local

anesthetic of the nupercaine type is desirable for those operations which cannot be completed in less than two hours.

It is a remarkable fact that the more active local anesthetics are often used in doses comparable to those of procaine, in entire disregard of the known difference in toxicity. It is no cause for wonder that fatal accidents have resulted from such misuse of these local anesthetics.

1 The 2 per cent solution of nupercaine is intended for local application in the throat and nose, procaine is preferable for injection, or one may inject small amounts of nupercaine 1 1,000, to which may be added one-tenth its volume of epinephrine solution 1 1,000, that is, 0.1 cc of the epinephrine solution to each cubic centimeter of nupercaine solution 1 1,000. Necrosis of the tissue may occur after the use of any local anesthetic, and one does not know in any case when such an accident may happen. It occurs but seldom when any of the local anesthetics is used properly.

2 It is distinctly dangerous to inject an effective dose of any of the local anesthetics in common use into the urethra in the presence of trauma. Disregard of the oft repeated warning has been responsible for many fatalities. The manufacturers themselves urge great caution when injecting nupercaine into the urethra in greater concentration than 1 500, and it does not seem justifiable to use a solution of ten times that concentration. Some observers have found a solution of 1 2,000 effective.

3 The manufacturers warn of the danger of using a concentrated solution of nupercaine in the eye and state that drying and cloudiness of the cornea may result from the use of a solution of 1 100. They state that it may be used in the eye with safety in the concentration of 1 1,000.

#### PSYCHOSIS OF GAS POISONING

*To the Editor*—What effect would the following composition of fumigating gases have on a patient eighteen months after exposure: cyanide chloride, cyogen chloride, sodium cyanide and inert materials? The specific case I have reference to concerns a woman aged 25, well developed, well nourished, fairly intelligent, circumstances poor. She and her sister were both overcome by the foregoing mixture of gases when an adjoining apartment was fumigated in November 1932. What followed immediately afterward is rather vague, although the sister was evidently unconscious for several hours but recovered. My patient ran to an open door when she felt herself becoming dizzy and did not lose consciousness. There was some vomiting, with considerable fright. I saw her for the first time in February 1934. She said that she had not been well since the accident, although no physician had attended her. Chief complaints were sinking spells with her heart, insomnia, flatulence and general weakness. The former history was negative except for renal calculus years before. Examination of the heart and lungs was negative. There were no murmurs. The pulse was rapid (120). The blood pressure was 120 systolic, 70 diastolic. The thyroid was palpable. No other signs of toxic thyroid were present other than the rapid pulse. A basal metabolism test and roentgen examination of the chest were not made as the patient refused to assume financial obligations for this work. The conjunctivae were very pale. No symptoms were obtainable in the abdomen. No tenderness or masses were found. Examination of the extremities was negative. The patient was placed on an iron tonic and bromides. Feeling that she was not making progress, she requested a consultation. The consultant diagnosed the case as neurasthenia from the bizarre symptoms and absence of physical changes. At present the patient is ambulatory, but contents herself with short walks and spends much of her time sitting in an easy chair or in the porch swing. When asked how she feels, she says that her heart sinks all the time. The sister has been under the care of a physician almost continuously since the accident and while she appears much the less robust of the two, she is able to get about quite well. Neither has worked since November 1932. A lawsuit is pending. My opinion is that the patient will make a rapid recovery when a settlement is made. What I want to know is whether you think her trouble would likely be due to the experience she had in 1932. What are the sequelae in patients who have recovered from cyanide gas poisoning? Two doctors who have gone over her carefully have said there is just nothing that you can put your finger on in this case, and I am admittedly up a stump. Can you help me? Kindly omit name if published.

M D, Indiana

*ANSWER*—The symptoms here described originated in fright, not in the physical effects of the gas. Henderson and Haggard in "Noxious Gases," page 112, say that "nonfatal cases of poisoning (by hydrocyanic gas) result in headache, a feeling of suffocation, and some nausea, these symptoms pass off after several hours." Hamilton in "Industrial Poisons in the United States," pages 348, 350, says that "chronic cyanide poisoning from HCN and its compounds is certainly rare and there are even skeptics who refuse to believe that any indubitable cases have ever occurred." This author quotes from Reed (*J. Indust. Hyg.* 2:140 [Aug. 1920]) reports of cases exhibiting dizziness, nausea, lacrimation, blurring of vision, gasping, coughing, staggering, prostration and irregular pulse. The men with these symptoms had been exposed every day for months. Authorities agree that, if death does not result from the immediate effects of cyanide poisoning, recovery is rapid and complete.

#### PTERYGIUM OR MALADIE DE CROCODILE IN PAPYRUS EBERS

*To the Editor*—Costomiri, page 50 in his book on ophthalmology of ancient Greece, quotes Ebers as saying in the papyrus that the name *maladie de crocodile* is applied to the pterygium because of a resemblance with the head of that animal. Hirschberg does not confirm what Costomiri has to say. I have neither the history nor the papyrus, yet I should like to have something definite on this point.

T. J. DIMITRY, M.D., New Orleans

*ANSWER*—It is rather difficult to answer this question without having the original papyrus of Ebers at hand. Ebers (George Moritz Ebers, a German Egyptologist, 1837-1894) obtained this famous papyrus from a citizen of Luxor in the winter of 1873-1874 and published the first edition in 1875. The papyrus was 30 cm. high and over 20 meters long and was written in hieratic script. Ebers' edition covered 108 pages, each with from twenty to twenty-two lines. Eight pages are devoted to ophthalmology, but the demarcation of this section was not sharp. The first complete translation of the papyrus was published by Dr. H. Joachim of Berlin in 1890.

According to this translation, the section on ophthalmology seems to end with a "Method of removing fat (Xanthelasma) from the eye, Messerstein in frischer Milch mischen und sehr häufig auf das Auge bringen." Then follow several formulas to be used in case of a bite by a human being. These are followed by this paragraph:

"Zu machen gegen den Biss eines Krokodiles," to which Joachim has appended the following footnote: "Eigentlich gegen den Krokodilrachen. Ebers, der diesen kleinen Abschnitt noch wie oben erwähnt zu den Augenkrankheiten rechnet, sieht hierin eine Augenkrankheit, nämlich das Pterygium. Er hat wohl übersehen, dass oben (Tafel 59,1) adēt anders determiniert ist als hier und dass oben vor allem von 'adēt mērt' die Rede ist, cfr. auch Tafel 59,10." This may be translated as follows: "Ebers considered that this small section belonged to the section on ophthalmology, as was mentioned previously, and believed that this referred to a disease of the eye, namely, pterygium. He evidently overlooked the fact that in plate 59,1, adēt was determined as having another meaning and that especially in this section, the question dealt with adēt in mērt (compare plate 59,10)."

The question seems to simmer down to the rendition of adēt. According to Ebers it could refer to pterygium, but his reasoning here is rather weak. Hirschberg translates it as ocular carcinoma, but he himself questions the validity of the rendition. Lüring offers the most logical translation as injury, which seems to fulfill all requirements. If this is accepted the section in question deals purely and simply with the bite of a crocodile and has nothing to do with diseases of the eye.

#### TREATMENT OF CARDIAC DECOMPENSATION

*To the Editor*—A patient of mine is a 46-year-old woman with a badly decompensated cardiac condition who is being given 1 cc of salyrgan intravenously once a week. Following the first four injections marked subjective improvement was noted. Following the last two injections, however, she has had rather abrupt drops in her systolic blood pressure from 200 to 140 or 150 mm. of mercury. Accompanying this drop she has had severe aching, slight febrile reaction and marked weakness. The reaction came on in each case approximately four hours after the injection and persisted until the blood pressure had been elevated to its former level by repeated small injections of epinephrine. Urinalysis reveals a trace of albumin and very occasional hyaline casts. Moderate diuresis has followed each injection. Kindly inform me whether the salyrgan should be stopped. Please omit name.

M D, West Virginia

*ANSWER*—Reactions from salyrgan in 1 cc doses are infrequent, particularly when used in patients with edema.

Mercurial diuresis is intimately associated with the available sodium chloride and during mercurial diuresis large quantities of sodium chloride are eliminated in the urine. When salyrgan is used, the sodium chloride reserves of the body often become depleted, particularly if the patient is on a low sodium chloride intake. When this occurs the diuretic effect of the drug is decreased but can oftentimes be enhanced again by giving preliminary doses of sodium chloride. Furthermore, some authors have felt that following sodium chloride depletion in the body further doses of salyrgan may give reactions as a result of hypochloremia.

The question does not state whether preliminary treatment to salyrgan medication was given. This is important, because if salyrgan diuresis is enhanced by other innocuous drugs such as the acid base salts, it is not necessary to give salyrgan as often to obtain the same results. The following regimen is suggested:

The patient is given 4 cc of a 40 per cent solution of ammonium nitrate three times a day in half a glass of water after eating. Then the salyrgan is given not oftener than every

three days. On the second day after the salyrgan the patient should take a saline cathartic.

If the patient becomes nauseated from the ammonium nitrate, hydrochloric acid 5 per cent can be substituted with good results. The dose commonly used is 4 cc three times a day in half a glass of water after eating. Ammonium chloride is considered by some preferable to ammonium nitrate.

#### PREGNANCY IN PATIENT WITH ONE KIDNEY

*To the Editor*—I should like your advice on the following problem. A woman aged 41, has two living children aged 18 and 20 years. About ten years ago she had one kidney removed following its almost complete destruction as the result of obstruction of the ureter by a stone. In the past three years she has had two or three spontaneous abortions in the early months of pregnancy not apparently associated with any signs of low renal function. She earnestly desires another child. My questions are: 1. Would you advise against any woman with only one kidney becoming pregnant? 2. If so, what results of what kidney function tests would you expect before you advise such a woman that she could successfully withstand the demands made on her organism by a pregnancy? 3. Is it possible that her abortions were the protective acts of nature against a possible damaging of her one kidney?

LEON PARIS M.D. Bronx N.Y.

*ANSWER*—1. A woman with one perfectly functioning kidney usually stands pregnancy and labor well and therefore, in the absence of other contraindications, may take the slight risk.

2. Of the kidney function tests during pregnancy only one has proved even partly reliable, the urea clearance test, and even this one has to be discounted somewhat since urea clearance is naturally lower during gestation.

3. It is possible that nature throws off an offending parasite (the ovum) by abortion to protect an inadequate renal function. Kidney disease may exist with minimal symptoms and tests may not discover it. Many evidences of this exist in the "latent nephritis" of older authors and "low reserve kidney" of Williams and Stander. Indeed, there are rare cases in which the only evidences of maternal kidney damage are to be found in the fetus and the placenta of the aborted ovum—particularly the placenta.

Have all the other causes of habitual abortion been ruled out in this case?

In this particular patient it is justifiable to let pregnancy supervene if at present no renal inefficiency is discoverable, treat the case as if there were latent nephritis, and watch with exceeding care for the very first manifestations of kidney trouble. This means, most of all, clinical supervision but with aid from the laboratory. In addition to urea clearance tests, nonprotein nitrogen, creatinine and blood concentration readings must be made regularly.

#### PARAFFIN BATH METHOD FOR ARTHRITIS

*To the Editor*—Kindly give details regarding the paraffin bath for rheumatoid arthritis of the interphalangeal joints of the fingers. Kindly omit name.

M.D. Pennsylvania

*ANSWER*—The equipment for treatment by means of hot paraffin dips includes a metal or enamel-ware container which may be of various shapes and sizes, cakes of paraffin, and a heater.

The container may be the ordinary double boiler that is used in cooking cereals. It may be the shape of an electrical sterilizer. It may be the shape of a large coffee pot. It may be like a small clothes boiler used in the laundry.

For the hand and arm, a container shaped like a medium-size electrical sterilizer is filled two-thirds full with paraffin, which can be melted by gas or electric heat. The paraffin comes like cakes of chocolate. The Standard Oil Company puts out a satisfactory product. These cakes are put into the container and heated to the melting point. One may use a thermometer in order to keep the temperature between 118 and 136 F. A simpler method is to keep the heat at the point where it will melt the bulk of the paraffin, but a fresh half cake will remain in solid form at the bottom of the container.

The patient stands or sits and plunges his hand and lower forearm into the hot paraffin and removes it after from ten to thirty seconds. A coating of paraffin adheres to the part. At the end of from thirty to sixty seconds, when the coat is dry, the hand and forearm are again plunged in and another coat is added to the first. This process is repeated at intervals of from thirty to sixty seconds until six or eight coats have been applied.

The hand is then removed, placed on a pillow and remains for a period of from eight to ten minutes. The entire period, from the time the hand is first placed in the paraffin until the entire paraffin glove or gauntlet is removed should occupy from fifteen to twenty minutes.

#### MASTODYNIA

*To the Editor*—I would welcome therapeutic suggestions in the following case of mastitic engorgement. A woman, aged 27, married with one child, aged 5 years, had an oversupply of milk during the nursing period and the milk was pumped out of her engorged breasts and fed to other infants. She tries to limit her fluid intake because immediately after fluids are taken, her breasts undergo enlargement. As she puts it, everything that she drinks runs to her breasts. She has a slight tendency to obesity, but her breasts are out of proportion to the rest of her body and she feels self-conscious. Before the menstrual period the breasts undergo similar hypertrophy. Kindly omit name.

M.D. Massachusetts

*ANSWER*—The engorgement of the breasts in this case most likely is due to some endocrine disturbance. It may be related to the condition of "painful breasts," or mastodynia, which many women experience just before or at the menstrual periods. It occurred to Cutler (*THE JOURNAL*, April 11, 1931, p. 1201) that the syndrome of "painful breasts" might be associated with diminished follicular function. He has obtained good results with hypodermic injections of estrogenic substance. G. Van S. and O. W. Smith (*Am. J. Physiol.* 103:356 [Feb.] 1933) showed that large doses of estrogenic substance (e.g., theelin) prevent lactation in rabbits after parturition. This has since been shown by other workers to result from suppression of the anterior pituitary, which secretes the lactogenic principle. In the experiments of the Smiths it was not always possible to inhibit lactation by estrogenic substance after the secretion of milk had continued for some time. Desiccated thyroid may be tried, because it not only inhibits the secretion of milk but also acts as a diuretic. Wachtel (*Zentralbl. f. Gynak.* 53:987 [April 20] 1929) successfully used thyroid to diminish the flow of milk in women. Pituitary extract definitely diminishes or stops the flow of milk in animals. Fauvet (*Arch. f. Gynak.* 155:100, 1933) succeeded in inhibiting the flow of milk in 121 out of 123 women by administering thyroxine tablets and phenobarbital.

#### HEREDITY IN HARELIP

*To the Editor*—A young couple, both university graduates, have recently consulted me in regard to the possibility of having another child. One year ago they had a baby born with a harelip although the pregnancy was apparently normal. The question asked me was: "In the event of another child, what are the possibilities of a recurrence of harelip or some other anomaly?" The mother has recently been examined by a physician, who suggested a possibility of a hypothyroidism. A basal metabolism test has been arranged for. Is there anything that can be done to assist in the prevention of such an anomaly? Is harelip a recessive or a dominant trait? In view of the chances of a recurrence is it best to advise those parents to have no more children? Kindly withhold name and address.

M.D. California.

*ANSWER*—The available statistics would suggest that there is a hereditary predisposition in something like 30 per cent of the occurring cases of congenital facial clefts. However, if there are no other cases in the family there is probably no more reason to expect other children to be so afflicted than in a family with a negative history of such a deformity. There does not seem to be anything that can be done to assist in the prevention of such an anomaly, although there is a suggestion that some of these cases are associated with extreme vomiting early in pregnancy. In some others the mother gives a history of having had a serious tooth complication early in pregnancy, but the relationship of this to the occurrence of harelip is not conclusive. Harelip is a negative and not a positive condition, and there probably are as many causes for it as there might be for a fracture of a leg. There is no apparent reason why the parents should be advised not to have other children. If properly cared for, these children are about as well off as the average.

#### FRACTURE OF THE OLECRANON

*To the Editor*—What is the latest approved method in treating a complete fracture of the olecranon? A advised an open reduction with the elbow maintained in flexion while B advised closed reduction and extension. Is flexion now the preferred position when the closed reduction is used? Please discuss with regard to functional recovery and length of convalescence. Please omit name.

M.D. New York

*ANSWER*—The treatment of this case depends on several factors, including the degree of separation, occupation of the person, risk of operation, equipment from the standpoint of the hospital and surgical team and whether the fragments can be perfectly approximated when the elbow is in extension. In fracture of the olecranon, under anesthesia with gas, the arm may be completely extended and the smaller fragment manipulated in line with the larger one. If it can be perfectly approximated, a plaster-of-paris cast may be applied with the elbow in extension for about three weeks. Then the cast is

bivalved so as to apply radiant heat, gentle massage and careful flexing movements twice daily. If the fragments cannot be perfectly approximated, an open operation consisting of approximation of the fragments, four drill holes inserted and the fragments united by living suture, such as fascia lata, may be attempted. In many cases the smaller fragment is only a flake of bone and cannot be drilled sufficiently to permit suturing by this method. In that case, catgut is used.

#### POSSIBLE EPILEPSY

*To the Editor*—A man aged 58 a lawyer, has spells at night of jerking muscles of the body and legs that wake him up. The condition is severe as the jerks are violent and they even draw his legs backward but they do not occur in the daytime nor have they interfered with his work. But they may keep him awake half the night more or less. His physique is good. He hunts and fishes and is active. The jerks have persisted for several years but they are getting worse and now he seems to get a pressure or pain in his head with the attack. Physically he is well. The urine is normal. He eats properly. He has a good business with a large clientele. He smokes cigarettes quite freely. He has used considerable liquor in years past and was addicted to quite a spree now and then but usually was ready for business when needed. He is pleasant and affable but when the jerking spells seize him he curses and becomes angry. In fact he is said to have gotten up recently and pounded with his fists. He even threw a glass and broke it. Then he cleaned up the pieces and simply told his wife that he had had a terrible night and dismissed the subject. I have urged him to go to a neurologist and be checked up but so far have not been able to get his consent so I am writing to you for advice. M D Minnesota

**ANSWER**—Your advice to the patient is eminently sound, as it is obviously essential for a rational therapy that a thorough examination be made, general as well as neurologic. The account given suggests that the seizures are of an epileptic nature, though no guess can be hazarded as to their etiology or significance. The onset of seizures late in life—the date of onset is not given—always suggests an organic basis which should be discovered if possible. Temporizing is unwise and one would hesitate, if not refuse, to advise any merely symptomatic therapy.

#### TOXICITY OF DIBUTYL PHTHALATE

*To the Editor*—Kindly advise me whether the handling of dibutyl phthalate is in any way injurious to the health of an individual. Is there any connection between the handling of this drug and kidney stones? JOSEPH L. NORTELL MD Chicago

**ANSWER**—Dibutyl phthalate long has been used as a plasticizer in cellulose nitrate and acetate lacquers and in the manufacture of safety glass. No experience is known to have developed indicating that this substance possesses toxic properties. In free form this phthalate comes in direct contact with the skin of certain classes of glass workers. No skin irritation has been observed. Its high boiling point (340 C) is unfavorable to the ready formation of vapors. Burke, in an article entitled "Lacquers and Their Hazards" (*New York Bull Indust Hyg* April, 1932, p 23), states that phthalate esters may be considered free of health hazards. In the state of Ohio, wherein there is a compulsory system for the reporting of occupational diseases, apparently no cases of dibutyl phthalate poisoning have been recorded. While the total amount of information on the action of this phthalate on the human body is scanty, the stand may be taken that no sound reason exists for the attribution to this agent of the formation of kidney stones.

#### ESTIMATING BASAL METABOLISM IN PATIENT WITH AMPUTATION

*To the Editor*—How can the basal metabolic rate be estimated in a male patient with bilateral mid-thigh amputation? This patient has a pulse rate of 94 and a blood pressure of 160 systolic 94 diastolic. Can the increased pulse rate and elevated blood pressure be attributed to the amputation assuming that the general physical examination is negative? M I MENDELOFF MD Charleston W Va

**ANSWER**—Aub and Du Bois (*Clinical Calorimetry, Arch Int Med* 19 840 [May, part 2] 1917) discuss the basal metabolism of dwarfs and legless men. They conclude that "the law of surface area holds good for men of unusual body shape." Based on this authoritative statement, which has never been disputed, calculations in this case are the same as in any other individual. One would therefore proceed as in the following sample calculation in an "assumed case with a bilateral mid-thigh amputation. Mr X, aged 43, height 105 cm weight 58.8 Kg, body surface 1.19 square meters, total calories per hour determined by basal metabolism test 517, or 433 calories per square meter of body surface. The predicted normal (Aub Du Bois) in this case is 385 calories for each square meter

per hour. This represents, in this assumed case, a basal metabolic rate of +13. The body surface is conveniently obtained by the use of the well known nomographic body surface chart of Boothby and Sandford (*Du Bois Basal Metabolism in Health and Disease*, edition 2, p 120, also table 29, p 169). It is quite evident that in the application of the body surface formula the loss of weight by amputation compensates to some extent for the reduction, if any, in body height even in a one legged subject.

One of the legless men discussed by Aub and Du Bois (p 848) had a blood pressure of 188 systolic, 130 diastolic. This hypertension, however, can be accounted for by the other clinical observations reported. Although data on this point are not obtainable at present, a normal blood pressure should be expected in a normal individual after full recovery from the amputation.

#### PALPITATION AND NERVOUSNESS AFTER PROCAINE AND EPINEPHRINE

*To the Editor*—It has come to my attention that occasionally after the injection of a local anesthetic solution such as procaine combined with epinephrine the patient complains of palpitation and nervousness. Kindly outline the anatomic course of the impulse generated by the vasoconstriction at the site of the injection (for example an injection surrounding the tonsil) to the structures involved in producing the subjective symptoms of palpitation. Do you know of any method of preventing these symptoms from developing in sensitive patients?

H C SCHOLER MD, Detroit.

**ANSWER**—These are not uncommon symptoms following such injections. Unfortunately, a general satisfactory explanation cannot be offered. The palpitation of nervousness following injections of procaine solution containing epinephrine is not due to a reflex generated at the site of vasoconstriction but probably to the following factors:

1 Anxiety and fear of operation in highly nervous individuals which will induce palpitation and this, in turn, more nervousness.

2 A too rapid entrance into the circulation of some of the epinephrine and procaine from the site of injection.

3 The possibility that at the time of injection the point of the needle may empty directly into a small vein and hence a fairly large quantity of the substance enter the general circulation rather rapidly.

4 Hypersusceptibility of some individuals to both epinephrine and procaine and its allies. Patients with hyperthyroidism, many women at the menopause, persons with hypertension, and those with neurocirculatory asthenia are said to be highly susceptible to epinephrine. All the commonly used local anesthetics have caused such untoward symptoms, which have been attributed to idiosyncrasy or hypersusceptibility.

There is a possibility that these symptoms may be prevented by the preliminary administration of a sedative such as barbitol, about 0.3 Gm (5 grains) by mouth, half an hour before the local injection is made. Secondly, all injections should be made rather slowly precautions being taken to avoid the possibility of direct entrance of the needle into a vein. With slow injection the operator may better detect an idiosyncrasy to the drugs.

#### PARALYSIS OF CONVERGENCE OF EYES

*To the Editor*—A man, aged 23 presents a negative medical history until six months ago when he began to get attacks of a "feeling of uncertainty" about him and his eyes just seemed to gaze into space. He was examined several times but nothing seems to have been found. Refraction gave no relief. Recently I examined the patient the only significant observations were in the eyes. The left pupil is slightly larger than the right. Both react to light but only feebly in accommodation. The eyegrounds are normal. The patient is able to move his eyes in all directions freely but is unable to converge them. Convergence seems to be less on the left side. There is no nystagmus or squint. This appears to be more than an ordinary exophoria. The Wassermann reaction is negative. Urinalysis is negative. The visual fields are not altered. What diagnosis does this suggest? Is there any relation between the weakness of the left interior and the dilatation of the pupil? Where is the lesion? Is there any treatment?

M D Pennsylvania

**ANSWER**—The one missing point in the enumeration of symptoms is whether diplopia exists or can be elicited and whether such diplopia is for distance or for near. The rectal indicates a paresis of convergence, which is not at all uncommon. True paralysis of convergence, according to Bielschowsky, does not exist whereas a weakness or paresis of convergence is a well recognized clinical entity. This is, of course, in direct connection with the lack of convergence reaction of the pupil, as the centers of convergence and of pupillary contraction to convergence or accommodation are side by side and are stimulated simultaneously. These centers are in close asso-

ciation with the third nucleus but anatomically are probably located in the occipital cortex. The most common cause of this trouble is epidemic (lethargic) encephalitis although other cortical lesions must be taken into consideration. The treatment must be based on the underlying cause.

#### LIQUID FACE POWDER

To the Editor—Have you a formula for a liquid suspension powder which is known in the cosmetic trade as a liquid face powder? Could something like this be used as a medium for pigments to be applied over disfiguring marks on the face or arms? I mention this type of preparation because of the fact that it covers better and seems to cling to the skin better than the dry powder dusted or rubbed on. Kindly omit name.

M D Minnesota

ANSWER—Calamine lotion, composed of calamine powder, a pink crude zinc carbonate, and zinc oxide in lime water is such a so called liquid powder. Any suitable inert insoluble powder can be used. If used on dry skin, equal parts of lime water and rose water will probably be more agreeable. A small amount of glycerin may be added if this combination is too drying.

Zinc paste composed of 25 per cent of zinc oxide, 25 per cent of starch and petrolatum or ointment of rose water 50 per cent is another good covering preparation.

#### IONIZATION OF NASAL MUCOSA

To the Editor—Have you any data concerning the origin of the fad for ionization of the nasal mucosa which is so extensively exploited at the present time? My own information is to the effect that it was initiated by an electrical engineer in San Antonio Texas who sold the idea to the present manufacturers.

CHARLES H EYERMANN M D St Louis

ANSWER—It is difficult to state absolutely the origin of the employment of ionization of the nasal mucous membrane. There is herewith submitted a list of references beginning in 1917 and ending with a recent paper by Dr Harold L Warwick in the March issue of the *Laryngoscope*.

- Kesteven L. Notes on Ionic Medication and the Method of Administration. *Brit M J* 2: 423 (Sept 29) 1917. This article contains a brief paragraph on the reduction of enlarged turbinates.

#### TREATMENT OF OLECRANON BURSITIS

To the Editor—I am treating a healthy man aged 53 for an olecranon bursitis which followed a bruising of the left elbow on his car door a month ago. Hot applications, rest and light bandaging have failed to cure it. Under strict asepsis I have aspirated it twice but it soon fills up again. The fluid obtained is a clear straw color tinged with blood. Would injection with some sclerosing solution cure it? Would such an injection affect the elbow joint in any way? What type of solution would you recommend should you deem this treatment advisable?

DONALD B KNOWLES M D Chicago

ANSWER—Injection with a sclerosing solution might effect a cure. One must be careful that there is no connection between the joint capsule and the bursal sac. The most commonly used preparations for injection are camphor and phenol compound solution of iodine and Pregl's solution of iodine. Some cases of olecranon bursitis do not clear up until foci of infection are removed, the most common being in the intestinal tract. Scarification of the bursal sac walls or excision may be necessary.

#### INCOMPATIBILITY OF ACETYSALICYLIC ACID (ASPIRIN) AND SODIUM BICARBONATE

To the Editor—I have had several minor arguments with several confreres about combining acetylsalicylic acid (aspirin) and sodium bicarbonate. I have always felt that since one is an alkali and the other an acid combining them in the same prescription is incompatible. Will you please tell whether or not they may properly be combined? If so what are the advantages? If not what are the disadvantages other than mixing any acid with an alkali? Please omit name.

M D Pennsylvania

ANSWER—The alkali decomposes the acetylsalicylic acid into acetic and salicylic acids. Hence the incompatibility is worse than merely any mixture of acid and alkali. There are no advantages in this mixture.

#### HONEY IN DIABETES

To the Editor—Would you please advise whether honey is permissible in diabetes? If so what quantity? If not what form of sweets can be given? Please omit name.

M D, Arkansas

ANSWER—That diabetic patients can tolerate honey better than other sweets has been reported at various times. However, the sugars in honey, including levulose, are not oxidized in complete diabetes, and this being true it is unlikely that the patient with mild diabetes is injured any less by honey than he would be by dextrose. Glucose sweetens without adding either sugar or calories to foods, and in divided doses not exceeding 4 or 5 grains (0.26 or 0.32 Gm) daily it appears to be harmless. Further details are given in Joslin's Manual for Diabetic Patients, ed 5 Philadelphia, Lea & Febiger 1933, or Wilder's Primer for Diabetic Patients, ed 5, Philadelphia, W B Saunders Company, 1934.

#### PIPERAZINE FOR RENAL CALCULI

To the Editor—Please inform me whether piperazine is of any value in dissolving renal calculi. Will its continued use cause any damage to the kidneys or other organs? Please omit name.

M D, North Carolina

ANSWER—Piperazine is of no value in dissolving renal calculi. It does not dissolve uric acid in the presence of sodium salts any better than any other alkali and, as part of it is oxidized in the system, its effect on the alkalinity of the urine and therefore its solvent power is less than that of sodium bicarbonate. It is virtually nontoxic.

#### NATURE OF INFECTIOUS DISEASE

To the Editor—Is there any disease which may be contracted a number of times and in which each succeeding exacerbation is less severe and also in which finally immunity is established?

STANLEY M GATES M D Monticello Ark

ANSWER—Tularemia and undulant fever appear to be good examples of the kind of infectious disease indicated in the question.

#### TRYPARSAMIDE IN SYPHILIS OF THE OPTIC NERVE

To the Editor In Queries and Minor Notes' August 11 appears a question from Dr W W Pike of Binghamton N Y on the use of tryparsamide in syphilis of the optic nerve. The answer to this query betrays unfamiliarity with the recent literature.

1 In part 1 of Dr Pike's query, he himself is in error in stating that Woods and Moore have shown improvement with tryparsamide in cases of optic atrophy. On the contrary Woods and myself have definitely advised against the use of this drug in optic atrophy and the authors to whom Dr Pike has reference are probably Cady and Alvis (*THE JOURNAL* Jan 16 1926 p 184). On the basis of my own experience with Woods I am therefore diametrically opposed to the answer to part 1 of this query and in my opinion it would be most unwise to use tryparsamide.

2 In response to the question "What is the present status of the Swift Ellis treatment in the treatment of optic atrophy?" the answer is given. There is no known treatment which can cure optic syphilitic atrophy [sic]. While it is true that no known form of treatment will cure syphilitic optic atrophy its progress can be arrested in about 50 per cent of the cases treated (provided vision in the better eye is 20/40 or more) by the use of subdural treatment. The literature on this point is summed up in an article "The Syphilitic Optic Atrophies" (*Medicine* 11: 263 [Sept] 1932) and is more briefly summarized in chapter XVIII of my recent monograph "The Modern Treatment of Syphilis" Springfield Ill Charles C Thomas.

3 To the question "Have any benefits been observed from the use of fever therapy in arresting optic atrophy?" the answer is an unequivocal No. This answer is quite untrue. Definite arrest of the progress of syphilitic optic atrophy in many cases has resulted from the use of malaria.

4 To the question "Is there any other treatment that you could suggest to arrest advancing impairment of vision and perhaps restore sight?" the answer is again No. As a matter of fact in the particular case described by Dr Pike the atrophy is apparently largely unilateral with normal fields and fundi in the right eye. The prognosis from either subdural or fever treatment in cases of this type is an extremely favorable one.

5 The benefits derived from malarial therapy are not thought by most observers to be mainly due to the rise of temperature and its persistence. References to this point may be found in chapter XXI of my own monograph and in many other papers prominent among which are:

- Bruetsch W L. Activation of the Mesenchyme with Therapeutic Malaria. *J Nerv & Ment Dis* 76: 209 (Sept) 1932.
- Bruetsch W L. Histopathology of Therapeutic (Tertian) Malaria. *Am J Psychiat* 12: 19 (July) 1932.

## Book Notices

**Foreign Body in Air and Food Passages Roentgenologically Considered**  
By Chevalier Jackson M.D. Sc.D. LL.D. Professor of Bronchoscopy and Esophagoscopy Temple University and Chevalier L. Jackson M.D. M.Sc. F.A.C.S. Professor of Clinical Bronchoscopy Temple University Philadelphia Volume XVI Annals of Roentgenology A Series of Monographic Atlases Edited by James T. Case M.D. Professor of Roentgenology Northwestern University Medical School Chicago Cloth Price \$12 Pp 265 with 145 illustrations New York Paul B. Hoeber Inc 1934

The material in this excellent monograph is selected from 3,000 cases in the authors' own experience and is representative of practically every form of pathologic change resulting from or complicating a foreign body. The book covers the subject from the clinical point of view and its brief but ample text, numbered by paragraphs, is well illustrated by 145 roentgenograms. Great stress is laid on systematic roentgen studies, and the routine procedure for all cases is clearly mapped out. Repeated exposures are recommended in doubtful cases and overexposures when superimposed pathologic change obscures the foreign body. Pre-existing pathologic change together with that produced by the foreign body is properly evaluated through roentgenographic studies, and every effort is made to learn the exact condition of the host as well as the type and location of the foreign body before the latter is removed. Certain definite axioms, the fruit of the authors' wide experience, with illustrative cases are clearly set forth in fourteen paragraphs. These bear on diagnosis in general and point out various complicating factors that may interfere with a proper diagnosis. An excellent chapter on biplane fluoroscopy should be well received by many who have read of this procedure but have not fully understood its details. The authors have been successful in removing 98 per cent of all foreign bodies. Such a high achievement was made possible only through the most meticulous attention to details and the closest cooperation between bronchoscopist and roentgenologist.

**Les prématures I—Physiologie du prématuré** Par H. Vignes professeur agrégé à la Faculté de médecine de Paris II—*Etude clinique et thérapeutique* Par G. Blechmann Paper Price 20 francs Pp 163 with 40 illustrations Paris Masson & Cie 1933

The first part of this book is in the form of lectures given at the Hospital of Charity, Paris, by Henri Vignes. These lectures are in effect a summarization of important books and studies in the field of pediatrics. The first chapter discusses the underdevelopment of the various organs of premature infants and indicates clearly why one three months under term cannot be raised, even under ideal extra-uterine conditions. Several graphs are included in the first chapter showing the intra-uterine growth in weight, the proportional increase in body height and the measurement of organs, the surface or area of the premature infant relative to weight, and other items. A table is presented showing the term and weight of several abnormally small premature infants observed by various pediatricians. The author emphasizes three circumstances that tend to aggravate the risks of immaturity, namely, obstetric injuries, intra-uterine conditions and hereditary diseases. The second chapter describes the potentiality of the various organs of premature infants for adaptation to extra-uterine life. Although prematurity is the most important cause of infant mortality and a high percentage of infants born prematurely cannot be saved, the author concludes that the premature infant has great potentiality of adaptation to extra-uterine life provided it is protected from exposure to cold, infectious diseases and gastro-intestinal disturbances. Emphasis is placed on the fact that the premature child has need for adequate nourishment, not only for the sake of growth, but also to produce heat, because his small body surface radiates proportionally much more heat than the full-term infant. The latter part of the book discusses the immediate effects of prematurity on a child and enumerates the various imperfections and retardations manifest during the first two or three years of life.

After indicating the distinction between the premature infant (born before term) and the infant with congenital weakness (born before or at term), the author presents in the second part a study of the cardinal characteristics of congenitally weak

infants. A classification is made of the different grades of prematurity, and the imperfections to be found in the various organs of such infants, as well as the complications of prematurity, such as sclerema, edema, infection and rickets, are studied. The elements of favorable and unfavorable prognosis are given, and mention is made of exceptions, as cited by Variot, Lambinoy and others. A premature infant whose weakness does not have a pathologic origin and who quickly gains in weight ordinarily develops into a normal child, among other premature infants, the development is not always normal. The author treats in a complete manner the different methods of feeding premature infants and cites the methods of certain foreign pediatricians. This is followed by a study of the hygiene of premature infants, the use of stimulants, methods of maintaining body temperature, and the therapeutics of the important diseases of the premature infant.

**Geschlechtsentstehung und willkürliche Geschlechtsbestimmung** Von Dr. E. Kramer Paper Pp 40 Berlin & Leipzig Deutsches Verlagshaus Bong & Co 1934

The pamphlet begins with a brief review and criticism of various antiquated ideas and erroneous popular beliefs regarding a possible control of the sex of human offspring. This introduction is followed by a rather lengthy exposition of the chromosome theory of sex determination. The assumption is then made that since there exists, in all vertebrate species studied, a more or less substantial deviation from the 50:50 sex ratio expected according to the sex chromosome theory, the process of sex determination must involve the working of an additional modifying factor, which, when identified, may prove exceedingly valuable to man in his effort to control the sex of his progeny. On the basis of the works of Bluhm (1924) and Unterberger (1930 and 1932) the author concludes that such a modifying influence, at least in man, is exerted by the differential  $pH$  toleration of the X and Y sperms. The slightly acid reaction given by the secretions of the human vagina and serving to protect the female genital tract from invasion of pathogenic bacteria offers a medium tolerated, within certain time limits, by both X and Y sperms. When, however, the acidity of the vaginal secretions is too high, the vitality of both varieties of sperm may be impaired to such an extent that sterility results. Unterberger, a Königsberg gynecologist, successfully combated this type of sterility by recommending an alkalization of the vaginal tract, before coitus, with an aqueous solution (strength not indicated) of sodium bicarbonate. The results of this treatment were both striking and instructive: quite unexpectedly, in all cases thus treated, only boys were born. Alkalization of the vaginal secretion apparently acted depressingly on the X sperm, so that only the Y spermatozoa were able to reach the oviduct and fertilize the ovum. With this idea in mind, Unterberger proceeded to advise the same manipulation to normal married women who expressed the desire of "having a boy." Again the offspring reported were invariably of the male sex. In later practice this worker simplified the technic of vaginal alkalization by instructing the husband to powder the glans penis, immediately preceding coitus, with dry sodium bicarbonate. This modification likewise proved to be effective. Thus far seventy-four cases, all with positive results, have been reported by Unterberger. All attempts, however, to influence experimentally sex determination in the female direction have as yet been unsuccessful. Similarly ineffective were endeavors to influence, in either male or female direction, the sex of the offspring in lower mammals. In most of the latter the secretions of the vaginal mucous membrane always give an alkaline reaction, and neither their further alkalization nor acidulation brought the expected results. In spite of these failures, which lead one to wonder whether the entire "discovery" is based on sound and fundamental biologic principles, the overenthusiastic author hastens to proclaim it as the beginning of a new era. He seeks, moreover, to explain such phenomena of human reproduction as the fluctuation in the sex ratio of the offspring from copulations at various periods of the menstrual cycle or in relation to the age of the mother, also on the basis of changes in the  $pH$  of vaginal secretion.

The booklet is written in a popular style and is apparently intended for the public. This practice of communicating directly

to the general public, as facts, matters which are still far from being substantiated and which still require extensive experimentation and rigid testing by qualified physiologists and clinicians, is objectionable and must be condemned. To the medical profession, however, the ideas expressed in the paper under discussion should serve as a challenge. The cooperation of men and women in medical practice will no doubt result, within a reasonably short time, in the accumulation of sufficient statistical data to confirm or disprove the effectiveness of the procedure suggested by Unterberger and approved by Kramer for artificial sex determination in the male direction, particularly since the operation involved is simple and harmless. It must, however, be made frankly clear to the intelligent layman whose interest is enlisted for this purpose that he is dealing here with an experiment and not with a new conquest which bears the "tested and approved" seal of science.

**Urinary Analysis and Diagnosis by Microscopical and Chemical Examination.** By Louis Heltzmann MD. With a chapter on the Determination of the Functional Efficiency of the Kidneys. By Walter F. Dannreuther MD. FACS. Professor of Gynecology and Director of Department New York Post Graduate Medical School and Hospital Columbia University. Sixth edition. Cloth. Price \$5. Pp 385 with 131 illustrations. Baltimore. William Wood & Company 1934.

This edition embodies extensive changes and additions. New chemical tests have been added, but the author has given only those examinations which can be performed by the technician or physician without the necessity of a complete chemical laboratory. The author stresses the great value of microscopic examination of the urine, when carefully conducted. He gives many original illustrations of the different epithelial cells found in the urine and emphasizes their value in the diagnosis of diseases of the genito-urinary tract. A small drop of thick urinary sediment evenly spread out under a cover glass and examined with the high power (at least 400 to 500 X) is essential for a satisfactory examination. There are chapters in part I on the histology and secretion of the kidneys, chemical examinations for organic and inorganic substances, proteins, carbohydrates and abnormal constituents. Part II contains microscopic examination and includes crystalline and amorphous sediments, cellular elements, mucus, connective tissue casts, micro-organisms and parasites. Part III contains microscopic urinary diagnosis with chapters on diseases of the kidney and its pelvis, diseases of the bladder, and diseases of the generative organs. A chapter on tests of renal function and one on the hormone tests for pregnancy complete the volume. There are numerous illustrations. This book can be recommended as one of the most complete works on urinary analysis.

**Leitfaden der Pathologie und Therapie der Kampfgaserkrankungen.** Von Dr. med. Otto Muntsch. Oberstabsarzt im Reichsheere Mitglied des Preuss. Landesgesundheitsrates. Second edition. Boards. 9.60 marks. Pp 110 with 33 illustrations. Leipzig. Georg Thieme 1934.

It is presumed that during the next period of major warfare large groups of the civilian population may be subjected to the action of war gases. This prospect has prompted the author to seek the cooperation of Red Cross units throughout the world in the collection and appraisal of all possible information bearing on the prevention and treatment of injuries resulting from exposure to these toxic chemicals. The author states in substance, "with this point in mind the purpose of this book is to offer such knowledge as has been gathered from the different parts of the world as to ways and means for protecting the civilian population against the ravages of war gases." In the several chapters are discussed such topics as the development of chemical warfare, the statistics derived from the late war, the general toxicology and classification of chemical fighting materials, the chemistry of the principal war gases, the special pathology and treatment of such war gases as phosgene, chlorpicrine, dichloroethylsulphite, lewisite, arsine, the oxides of nitrogen, and carbon monoxide. One of the most attractive features of this book are the numerous illustrations in color presenting the clinical appearance of various types of disorders following exposure to war gas. In addition, various illustrations in black and white and in color present the results of animal experimentation and the appearance of various organs at necropsy. At present this book holds only limited value in the practice of medicine. Against the day when thousands of

persons may be attacked through the medium of gas warfare it contains all the substantial information available to the best known means of preventing the malaction of war gases and the diagnostic treatment of these conditions when produced, together with extensive discussion as to the prospective effects following in the wake of acute damage after exposure to gas warfare materials.

**Frakturen und Luxationen. Ein Leitfaden für den Studenten und den praktischen Arzt.** Von Professor Dr. Georg Magnus leitender Arzt der chirurgischen Abteilung des Krankenhauses Berghausen in Bochum. Second edition. Paper. Price 3.60 marks. Pp 86 with 43 illustrations. Berlin. Julius Springer 1933.

The first edition of Professor Magnus's primer on fractures and dislocations appeared in 1925. This edition is no larger than the original. The book is offered as a help for students and general practitioners. It is not meant for surgeons. The material is divided into two parts: general and special. General considerations of fractures, as classification, mechanism, clinical picture, methods of examination and diagnosis, associated injuries, healing and interference with healing and general considerations of the handling of fractures occupy twenty-four pages. General considerations of dislocations are covered in five pages. The second—the special—part devotes six pages to fractures of the skull and head and five pages to the trunk leaving forty-four pages for presentation of fractures and dislocations of the extremities. The author takes up his subject in the most elementary manner, and there is nothing new in what he has to offer. Any first class single volume on surgery presents the subject at least as well, if not better. It is difficult to understand the need for such a volume. The illustrations are equally simple. The enterprise seems hardly worthy of a university professor, and there is nothing in the little volume to interest American physicians.

**Contribution à l'étude radiologique du sein normal et pathologique.** Par le Dr. Alexandre Espalliat G. de la Faculté de médecine de Paris. Travail de la clinique chirurgicale du Professeur Gossset et du laboratoire de radiologie clinique de la Faculté (Dr. Ledoux Lebard chargé de cours). Paper. Pp 154 with 18 illustrations. Paris. Librairie Louis Arnette 1933.

A brief review of the anatomy and histology of the breast is followed by a description of the various physiologic and pathologic changes which this organ may undergo. A careful description is given of the various benign lesions and their differentiation from malignant changes. Based on these anatomic, physiologic and pathologic considerations, the roentgenologic aspects of the mammary gland are thoroughly discussed and the utility of the roentgen study is evaluated. Forty-one cases are reported in detail by way of exemplifying the text. The author believes that the roentgen examination of the breast is of practical utility if carried out with sufficiently rigorous technique. Before attempting the interpretation of the pathologic lesions, the physician must become familiar with the aspects of the normal breast with its various physiologic alterations corresponding to the state of repose of activity and of atrophy of the gland. Due credit is given to the American investigators for their priority in this work.

**Medicine in Canada.** By William Boyman Howell MD. Anaesthetist in Charge Royal Victoria Hospital Montreal. LA. Clin. Medica. A Series of Primers on the History of Medicine. Edited by E. B. Krumbhaar MD. Cloth. Price \$1.50. Pp 137 with 6 illustrations. New York. Paul B. Hoeber Inc. 1933.

The author purposely gives a "relatively large amount of space to biographies of pioneer medical men in order to 'show not only the conditions under which medicine was practiced, but the relation of the practitioner to the community as well.'" The rise of the various prominent hospitals and medical schools is sketched from their humble beginnings in Quebec, Montreal and Toronto and short chapters are devoted to James Douglas, John Christian Schultz, Archibald Menzies, William T. Tolmie and John Sebastian Helmcken. The meagerness of preparation for the practice of medicine of the early physicians, the hardships endured by most of them in their contentions with the elements, hostile Indians and epidemic diseases, makes the account most fascinating reading. The picturesque "wild west" days of Canadian medicine are gone forever.

**Radiotherapy in the Diseases of Women** By Malcolm Donaldson B.A. F.R.C.S. M.B. Physician Accoucheur with Charge of Out Patients St Bartholomew's Hospital Cloth Price 7/6 Pp 131 with 16 Illustrations London Hodder & Stoughton Ltd 1933

As the author states, some books on radiotherapy are too dogmatic and optimistic, others express an unwarranted pessimism based on the disappointment of certain surgeons who seemed to expect that after a local application of radium every growth however far advanced, would disappear, together with all secondary deposits. This pessimism has been accentuated by the unsatisfactory results of treatment in small institutions with inadequate amounts of radium, especially when applied in an amateur fashion. Attention is called to the requisite of much specialized knowledge and suitable apparatus. The present work attempts to state an authoritative, unbiased opinion on the value of radiation therapy in gynecology. In spite of the existing lack of agreement on the optimum time factor, the optimum intensity and the optimum dose it is none the less true that radiation therapy has already revolutionized the treatment of many types of cancer, and there is little doubt that as more efficient methods are evolved and practiced the number of permanent good results will be considerably increased. Attention is called to the common mistake of considering radiotherapy as a technique employed purely for malignant diseases. Many benign conditions, such as menopausal hemorrhage, fibroids and tuberculosis, respond. Chapter II, on the biologic action of radium, is delightfully succinct, readable and satisfactory, in spite of its brevity. There are many tables of results in the British clinics as well as other clinics throughout the world.

**Corrective Physical Education** By Josephine Langworthy Rathbone M.A. Instructor in Physical Education Teachers College Columbia University Cloth Price \$2.50 Pp 292 with 153 Illustrations Philadelphia & London W. B. Saunders Company 1934

This book presents, for students of physical education and physical therapy, the essential facts of human anatomy and physiology as they pertain to the subject of corrective exercise. There is nothing original in the text except its arrangement and the emphasis placed on certain phases of the subject. The material has been gathered from medical literature and from clinical experience. The purpose of this little book is twofold. First, it aims to convince the student of health and physical education that one of his greatest concerns should be to help children and young people build efficient and beautiful bodies. Second, it aims to furnish the student with some basic fundamental facts and principles on which to build a sound program of reconstructive health and physical education.

**Archiv und Atlas der normalen und pathologischen Anatomie in typischen Röntgenbildern. Die kombinierte Enzephaloarteriographie** Von W. Lohr und W. Jacob. Fortschritte auf dem Gebiete der Röntgenstrahlen Herausgegeben von Prof. Dr. Grashof. Ergänzungsband XLIV. 1. Heft. Paper Price 16 marks Pp 83 with 75 Illustrations Leipzig Georg Thieme 1933

This work emanates from the surgical clinic of the state hospital at Magdeburg-Altstadt under the direction of Professor Lohr and from the state neurologic clinic at Magdeburg-Sudenburg under the direction of Professor Jacob. The collaboration of these eminent authors has resulted in a distinct advance in the diagnostic methods relating to cranial lesions. The dangers of the method are recognized as being similar to but no greater than those attending encephalography and ventriculography. The authors prefer the introduction of air into the ventricular system through a lumbar puncture rather than its introduction into a ventricular puncture. Thorium dioxide is used as the opaque substance for arteriography. The authors' technique for the injection is described. A 5 cm. incision is made over the anterior upper border of the sternocleidomastoid muscle down to the internal carotid artery. The needle is introduced quietly for about 1.5 cm and the roentgenograms made during the introduction of the opaque material. The injection has to be made quickly and the roentgenograms must be made promptly as the injection proceeds. Later films also have some value. Beautifully illustrative roentgenograms are reproduced, illustrating the topographic anatomy of the visualized blood vessels of the brain under normal and pathologic conditions. Cases reported include hemangioma of the face and brain, various cases of epilepsy, arteriosclerosis, hydrocephalus,

and brain tumors. Even should the diagnostician not care to undertake this method of injection, he will find it valuable to have in his reference library this beautiful atlas of illustrative roentgenograms covering the various subjects listed.

**Grundlagen und Praxis der Röntgenstrahlendosierung. Dosismessung und Dosiseinstellung** Von Prof. Dr. med. H. Holthausen leitender Oberarzt am Allgem. Krankenhaus St. Georg Hamburg. Gemeinsam mit Dr. med. R. Braun Assistent am Strahleninstitut des Allgem. Krankenhauses St. Georg Hamburg. Paper Price 18 marks Pp 249 with 180 Illustrations Leipzig Georg Thieme 1933

In recent years a complete revolution in x-ray dosage has taken place and the nations are now in agreement on an international unit of measurement called the roentgen, the symbol of which is r. Dosage meters of numerous types have been devised, and it is now possible with a small outlay for any physician practicing roentgenology to measure the output of his apparatus under various conditions and to give any desired dosage with reasonable accuracy. The physician must be specially trained in the production of radiation of given wavelengths and he must have the necessary apparatus with which to do this. The reading of the dosage, however, is not so complicated that any physician who sets himself up as a radiologist should feel excused from accurately measuring the radiation delivered to his patients. The present work is an attempt to explain some of the problems concerned in the effects of different doses of x-rays acting on the organism and the effects of the same dosage under different circumstances. The first part of the book is devoted to the physical aspects of the measurement of x-ray dosage, including an exhaustive treatise on the measurement of the quality and quantity of what constitutes a dose. The second portion of the book (from page 85 on) concerns the practical applications of existing knowledge of the physical and biologic effects. Readers who understand German will welcome this work as an authoritative, readable discussion of a complicated subject.

**Précis de sémiologie médicale appliquée** Par M. Chiray professeur agrégé à la Faculté de médecine de Paris et P. Chene médecin assistant à l'Hôpital Saint Antoine. Cloth Price 75 francs Pp 607 with 364 Illustrations Paris Masson & Co 1934

One of the contrasts between many of the French and English medical textbooks and the German and American ones is the condensation and smaller size of the former. There is probably a place for both types of books, the shorter serving as a more readable introduction to the subject, the latter usually being much superior as a book of reference. The book under review is of handy size and aims to be an introduction to medical symptomatology. The ground covered is amazing. Physiologic, anatomic, pathologic, clinical, roentgenographic and laboratory considerations are evoked for each of the systems of the body. Fever, alterations of the general state, skin diseases, syphilis and endocrine disorders are discussed. Considering the extensive nature of the subject, the book is remarkably accurate. As an introduction to medical students just entering their clinical years, such a book as this should be valuable. The obvious danger is that the attempted completeness might discourage the reading of more detailed textbooks on sections not adequately covered here.

**Allgemeinere und örtliche Betäubung. Zusammenfassende Darstellung für die Praxis auf pharmakologischer und klinischer Grundlage** Von Dr. Fritz Hesse Privatdozent für Chirurgie Dr. Ludwig Lendle Privatdozent für Pharmakologie und Prof. Dr. Rudolf Schoen Direktor der medizinischen Universitäts-Poliklinik zu Leipzig. Mit einem Geleitwort von Erwin Pajr. Paper Price 16 marks Pp 307 with 50 Illustrations Leipzig Johann Ambrosius Barth 1934

The collaboration of a pharmacologist, a surgeon and an internist in the preparation of a monograph on anesthesia is an excellent idea. There are many important questions in this field, which in the past were discussed by pharmacologists or surgeons alone, such a group study can only be of benefit to the subject. The pharmacologist, Dr. Lendle, discusses the general and local anesthetics with much clarity and a critical attitude. The chapter on tribrom-ethanol and two other barbituric derivatives, pentothon and evipan, which are now under trial in Germany, is instructive. There is not much that the American medical profession can profit from the technical part written by the surgeon, Dr. Hesse. The description of methods in general and local anesthesia is rather brief, the illus-

trations are from other well known textbooks, some of them definitely antiquated. The most valuable part of the book was written by the internist, Professor Schoen, who discusses constitutional factors, diseases of the circulation, respiration, metabolism and the kidney in their relation to anesthesia. Particularly the preoperative investigation of the cardiovascular system is interesting, although it is perfectly obvious that a simple reliable test for latent myocardial insufficiency is still lacking. The book is recommended to all those who believe in a group study of patients coming to operation.

## Medicolegal

**Workmen's Compensation Acts Testimony of Experts Who Ignore Uncontradicted Evidence Evaluated**—Daugherty, 48 years old and in good health, seemed to catch his heel in some way while descending a stairway in the course of his work. He fell backward and when he got up he seemed "dazed." No wound was observed. He was assisted to a place where he could sit down and was left there. The accident occurred Aug. 24, 1931, about 7 o'clock in the morning, near the end of the night shift on which Daugherty was employed, and he arrived home about the usual hour in the morning. From the day of his fall his health continued to fail. Ultimately he ceased work. On January 22, 1932, he died. The cause of death stated in the death certificate was "epilepsia caused by clog on brain." Daugherty's widow and daughter instituted proceedings for compensation under the workmen's compensation act of California.

Before the industrial accident commission, physicians who had attended Daugherty testified that his death was caused by intracranial trauma and concussion, followed by intracranial hemorrhage, the result of an accidental fall. On behalf of the employer and his insurance carrier, three physicians filed written reports, which apparently were accepted as evidence. One of these physicians stated that "the record does not show that the employee's death was due to an injury sustained on August 24, 1931," and notwithstanding the undisputed testimony as to the fall, he reported that it was questionable whether Daugherty really fell. The other two physicians made a joint report, recording their opinion that Daugherty's disability and death were not due to the fall but that the fall was the result of a "petit mal" type of seizure, the initial symptom of a pre-existing lesion in the cerebrum. Daugherty, according to these two physicians, died from a pre-existing tumor of the brain. The industrial accident commission denied compensation. The claimants appealed to the district court of appeal, second district, division 1, of California.

If the opinions of the physicians called by the employer were based on correct assumptions of fact, said the court, they would unquestionably support the decision of the industrial accident commission. These opinions, however, were faulty in that they did not accept the uncontradicted facts about the accidental fall, which marked the beginning of Daugherty's pathologic history. Two of the physicians summoned by the employer reported that the most striking symptom was convulsions, which began on the day the patient fell, but that there was no evidence to show that any head injury occurred at that time. They admitted, however, that it was not necessary to receive a direct blow on the head in order to sustain intracranial damage. These two physicians, said the court, failed to recognize that Daugherty's first convulsion occurred several hours after the accident and that it was the first convulsion he had ever had, so far as could be ascertained.

The only foundation for the decision and order of the industrial accident commission, said the court, rested on the opinions of three expert witnesses, based on assumptions by them different from the established facts. The opinions of these witnesses were regarded by the court as insufficient to produce such a conflict of evidence as would make the determination of the case by the industrial accident board final. The court accordingly annulled the award of the commission denying compensation—*Daugherty v. Industrial Accident Commission (Calif.)* 27 P (2d) 774.

**Workmen's Compensation Acts Bronchial Asthma or Anthracosis Due to "Accident"**—The claimant's employment with the defendant oil refining company required him to clean the petroleum coke out of stills. While doing so he was exposed to gas fumes and coke dust. On April 14, 1931, there were more fumes than usual in the stills, which caused him to vomit and to suffer from shortness of breath. He became temporarily totally disabled, from what one physician stated was bronchial asthma and another diagnosed as anthracosis, and subsequently instituted proceedings for compensation under the Oklahoma workmen's compensation act. On his behalf, two physicians testified, in effect, that the excessive quantity of fumes present on April 14, while not the sole cause of his condition, was the exciting cause. The state industrial commission awarded him compensation. The employer brought an action in the Supreme Court of Oklahoma to reverse the award, contending that the claimant was suffering from an occupational disease not compensable under the act, and not from a compensable accidental injury.

It is well settled, said the Supreme Court, that the Oklahoma workmen's compensation act does not apply exclusively to traumatic injuries. The act provides compensation for "accidental injuries." The adjective "accidental" does not indicate the existence of an accident but rather that the injury was either unintended or unexpected. An "accident" such as is contemplated by the act is distinguished from an occupational disease in that it arises from some definite event the date of which can be fixed with certainty, which cannot be done in the case of an occupational disease. Under the evidence here presented the condition of the workman was probably progressively brought about by the inhaling of gas fumes and dust for a period of time, but on a definite and specified date he went to work as usual and after working a short time became suddenly ill and was unable to work further. The evidence is that on this certain date he had reached his limit and that the breathing of the gas fumes and coke dust on this particular occasion was the exciting cause of his present condition. Under the circumstances his injury is the result of an accident and is not an occupational disease. The Supreme Court accordingly affirmed the award of compensation made by the industrial commission—*Johnson Oil Refining Co v. Guthrie (Okla.)*, 27 P (2d) 814.

## AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

### Alabama Medical Association Journal, Montgomery

4 140 (July) 1934

- Treatment of Congestive Heart Failure T E Harrison Nashville Tenn—p 1
- Recent Advances in Treatment of Chronic Bronchitis J F Ahlson and J P Chapman Selma—p 3

- Effect of Thyroid Deficiency on Skull Growth in Sheep T W Todd and R E Wharton, Cleveland—p 97
- Structural Changes During Contraction in Striped Muscle of Frog H E Jordan, Charlottesville Va—p 117
- \*Studies on Experimental Rickets in Rats I Structural Modifications of Epiphyseal Cartilages in Tibia and Other Bones G S Dodds and Hazel C Cameron Morgantown W Va—p 135

Modifications of Epiphyseal Cartilages in Rickets—Dodds and Cameron base their conclusions on the study of thirteen normal rats of both sexes, between the ages of 2 and 12 weeks and nineteen rachitic rats from 5 to 12 weeks of age. 1 Rickets caused impairment of the growth of the long bones by the action of slowing of cell multiplication followed by its practical cessation, failure of cartilage cells to grow to normal thickness and crushing of cartilage matrix due to weakness resulting from inadequate calcification. 2 In mild rickets the leg bones of rats continued to elongate at a reduced rate throughout the experiment. In severe rickets the leg bones grew in length for a limited time only. 3 The thickening of the epiphyseal cartilage in rickets is due not to accelerated growth but to retarded cartilage removal. 4 In mild rickets cell multiplication, cell growth, calcification of the matrix and cartilage removal all continue, but calcification and removal lag behind cell multiplication and growth with the result that the cartilage becomes somewhat thickened, mainly in the zone of fully grown cells. 5 In severe rickets after about three weeks, calcification and cartilage removal stop entirely, and in a short time cell multiplication and cell growth stop also. This produces a thickened cartilage that is in a static condition. After a time cartilage removal is resumed and progresses into the uncalcified cartilage in a modified manner which results in the production of the peculiar rachitic metaphysis. The number of enlarged cells in the elongated rows does not increase demonstrably after the third week. 6 Cupping is produced by a greater retardation of calcification near the axis of the cartilage than near its margin. 7 In severe rickets there is sometimes a rejuvenation and resumed mitotic division of the enlarged cartilage cells in certain areas which produces a structure much like ordinary hyaline cartilage.

### American Journal of Diseases of Children

**Cutaneous Lesions in Rheumatic Fever**—In an epidemic of acute rheumatic fever Chester and Schwartz observed that ten of twenty-one children showed cutaneous lesions as the predominating sign of the recurrence or exacerbation of rheumatic fever. The lesions were bluish, were not tender, and appeared mainly on the lateral surface of the legs and the extensor surface of the forearms. Most often they appeared as maculopapular purpuric spots and persisted for from one to six months. No scarring or desquamation followed their disappearance. During the period of observation, such cutaneous manifestations were not observed in children without cardiac conditions. In nineteen of these children an increased cardiac rate was an accompanying sign. Fever was present in a mild form on thirteen occasions. Pains in the joints and muscles choreiform movements, epistaxis and congestive cardiac failure were each present in two instances. Hematologic studies in these children during the epidemic showed a persistent secondary anemia in all, a leukopenia and a positive Schilling count in two, and a transient thrombocytopenia and a positive tourniquet test in one. In one instance the PR interval was prolonged. The appearance of cutaneous lesions in children who have already had rheumatic fever should be considered a criterion of reactivity just as many other manifestations are now accepted.

**Another Diagnostic Sign in Syphilis**—Biederman discusses a diagnostic aid which is concerned with a change in the appearance of the anterior pillars of the throat. The anterior pillars in the normal throat have a certain healthy pinkish color merging imperceptibly with the pink of the surrounding healthy mucous membrane. During the recent examinations of the throats of a large number of patients having so-called latent syphilis it was observed that frequently there was an associated change in the appearance of the anterior pillars. This change was apparently due to an alteration in color in which the pillars assume a dark, dusky red shade, in a well defined congested area. This area began at the base of the pillars and extended upward from 0.5 to 2.5 cm and was approximately from 6 to 10 mm in breadth. The appearance was that of a definite vascular congestion. In the examination of 469 syphilitic patients this sign was present in 69.1 per cent. Not every case of syphilis presented this sign, nor could every patient having this sign be proved to be syphilitic. This sign should not be

confused with the secondary erythema of syphilis, which may be localized only on the anterior pillars or be present on any other portion of the mucous membrane

**Cross Sections of Vessels that Form the Torcular**—The Gibbss studied specimens of falx, tentorium and occipital dura, removed in a single piece at the time of postmortem examination. They observed that the torcular usually directs the greater part of the flow from the straight sinus into the left lateral sinus and the greater part of the flow from the superior sagittal sinus into the right lateral sinus. The cross section of any given vessel in the torcular is extremely variable even relative to the cross section area of the other vessels in the same torcular. The cross section area of the right lateral sinus tends to be greater than that of the left lateral sinus.

**ST Segment of Electrocardiogram in Acute Rheumatic Fever**—Easby and Roesler report three cases in which, during the course of a rheumatic infection, the following electrocardiographic changes were seen. Of the ST (RT) segment a low or high take off, a convex upward bowing, a depression and an absence of the iso electric portion. Of the T wave iso electricity, low voltage, origin below the basal line, simple inversion and coves shaped inversion. The electrocardiogram approached a normal form if the rheumatic infection cleared up, but even at the stage of complete recovery there was in one case persistence of iso-electricity of the T waves. In none of the three cases was evidence of a pericardial effusion present. These changes, though not pathognomonic for rheumatic fever occur rather commonly, as a review of the literature shows. Anatomic studies from the literature are reported which support the conception that the ST (RT) and T changes express an alteration of the musculature caused by the effects of the acute infection on the coronary circulation.

**The Heart in Myxedema**—Lerman and his associates discuss the changes in the size of the heart and in the blood pressure of eighteen patients having myxedema under thyroid medication, supplementing the data of thirty cases reported previously. It appears to be characteristic of the heart in myxedema to be enlarged and to undergo appreciable shrinkage as the disease is ameliorated by the administration of thyroid substance. The electrocardiograms of these patients taken before treatment showed abnormalities. None of the patients showed congestive failure.

**Primary Glaucoma and Epidemic Dropsy**—Kirwan presents twelve cases that are illustrative of typical epidemic dropsy associated with glaucoma, from the study of which he points out that primary glaucoma in association with epidemic dropsy is due to toxins which contain bodies of the histamine group and that the glaucoma is of the chronic primary non-inflammatory type. The toxin circulating in the blood causes a vascular disturbance, which in some way upsets the normal function of the intra-ocular capillary endothelium as well as causes dilatation of the general capillary field, which leads to an increased output of tissue fluid. As the glaucoma is only part of a generalized disorder, the treatment should be medical if only a speedy method were known to rid the body of the toxins. The operative treatment is symptomatic and is intended to prevent permanent damage being done to the retina by the increased intra-ocular tension till the general disease has been cured by the elimination of the offending toxins.

**Pepsin in the Prevention of Abdominal Adhesions**—In the prevention of abdominal adhesions, Yardumian and Cooper used an extract of pepsin, first in hydrochloric acid and then in glycerin but free from iodine, in their experiments on forty-four rabbits, on which 104 laparotomies were per-

formed. Most of the animals survived the operations, but in those which died not a single case of intestinal obstruction was found at necropsy. Peritonitis and hemorrhage were the causes of death in all cases. To produce adhesions that may be considered permanent there must be sufficient trauma to produce an exudate capable of forming fibrin to a marked degree. Therefore the abdomen was entered through a midline incision, and the small intestine was rubbed vigorously with a gauze-covered finger for a distance of from 6 to 8 inches (15 to 20 cm) in several places. The peritoneum on each side of the incision was forcibly scraped with the sharp end of a scalpel. The contents of the abdomen were replaced and the abdomen was closed in layers, catgut being used for the peritoneum and dermal for the skin. Before the peritoneum was closed the pepsin fluid was instilled. The active principle of pepsin was extracted from hog stomach with a 0.4 per cent solution of hydrochloric acid and with glycerin and water. The strengths used ranged from 0.5 to 2 per cent. When the abdomen was reopened and required extensive separation of adhesions, further trauma was not employed except incident to separation. The pathogenic adhesions were subdivided into four types: filmy, fine, moderate and dense. The cases were divided into two classes: class 1, in which filmy, fine or no adhesions were obtained, and class 2, in which moderate or dense adhesions resulted. The hydrochloric acid extract was used in one series and the glycerin and water extract in another. The results were as follows: In group 1 hydrochloric acid was used and nineteen operations were performed, 45.5 per cent of the cases were in class 1, and of these 25 per cent showed no adhesions. In group 2 glycerin and water was used and twenty-two operations were performed, 63.2 per cent of the cases were in class 1, and of these 39.1 per cent showed no adhesions. In group 3 a 0.5 per cent solution of pepsin in glycerin and water and traumatization by scarification were used and twenty-two operations were performed, 86.4 per cent of the cases were in class 1 and of these 75.8 per cent showed no adhesions. In group 4 a 0.5 per cent solution of pepsin in glycerin and water was used and lysis was obtained without further irritation, twenty-one operations were performed, 62 per cent of the cases were in class 1, and of these 33 per cent showed no adhesions. In group 5 lysis was obtained with irritation and of the twenty operations performed 50 per cent were in class 1, and of these 25 per cent showed no adhesions. Since their results show the decreased tendency to the formation of adhesions, the authors assume that the benefit from the digestive action of the pepsin is realized before absorption takes place. There was a gradual decline in the incidence of adhesions, with decreased trauma and in the presence of pepsin. The greatest tendency in the reformation of adhesions is when trauma is induced in the presence of existing adhesions and their separation, indicating the futility of any effort to prevent the reformation of adhesions in cases in which additional trauma is induced.

**Effects of Vitamin D and of Calcium on Local Atrophy and Union of Bone.**—The observations of Fischer and Key indicate that local atrophy of bone is the result of local conditions and that it cannot be prevented or appreciably lessened by an abundance of vitamin D and calcium in the diet. Likewise the healing and union of bones appear to require a certain amount of time, and no evidence was found that the addition of vitamin D and calcium to an adequate diet will reduce this time. The authors' patients received an adequate diet and their results should not be interpreted as evidence that patients convalescing from fractures and operations on the bones should not receive vitamin D and calcium. It is probable that a diet deficient in vitamin D and calcium would lead to increased local atrophy and delayed union of bone. It is further to be noted that therapeutic doses of vitamin D and calcium do not cause increased local atrophy or delayed union of bones.

**Iodine Tolerance Test for Thyroid Insufficiency.**—Elmer describes an iodine tolerance test that he has found to be highly characteristic of thyroid insufficiency. In the performance of the test, 0.658 Gm of potassium iodide is dissolved dried at a temperature of 110 C, in 500 cc of iodine free water. This solution contains 1,000 micrograms of iodine in 1 cc. After sterilization the solution is kept in 13 cc (1,300 micrograms of iodine) amounts in dark phials. After the skin is disinfected with iodine-free alcohol the contents of the phial are injected intravenously and the patient is instructed to drink a glass of water every one or two hours for six hours. The drinking of water facilitates the output of the urine, which in hypothyroidism may be insufficient. The urine is collected within the first six hours after the intravenous injection of iodine. The elimination of iodine within twenty-four hours may show at times only a slight difference in cases of hypothyroidism and normal thyroid function, but the differences are markedly evident in the first six hours after administration. The author adds the following modification to the method described previously for the determination. From 1 to 15 cc of a 50 per cent solution of potassium carbonate is added to from 10 to 20 cc of urine in a nickel dish. This is evaporated on a water bath, dried in an electric oven at a temperature of from 70 to 80 C or over a gas burner, and incinerated in an electric oven with the presence of air or oxygen at a temperature of about 350 C within from ten to fifteen minutes. After the dish is cooled, a little water is added to the residue. The contents are minced with an agate pestle and filtered with an ordinary blotting filter, the filtrate must be clear or at the most slightly yellow. The filter is incinerated with its content in the nickel dish in an electric oven within ten minutes at a temperature of 350 C. After complete incineration the residue of the filtrate must be pure white. The rest of the procedure is carried out according to the method reported previously. The author investigated fifty-five cases of different diseases with normal or disturbed function of the thyroid. The proportion of eliminated iodine in urine within six hours after intravenous injection of 1,300 micrograms of iodine as potassium iodide showed in hypothyroidism (seventeen cases) a constant and marked increase and amounted to from 23 to 40 per cent, and in euthyroidism (nineteen cases) from 12 to 20.5 per cent. In hyperthyroidism (ten cases) and in nontoxic goiter (nine cases) it was either decreased (as much as 0.8 per cent) or normal. The increased elimination was also noted in three patients with hyperthyroidism to whom iodine had been administered previously. This fact does

not diminish the value of the test, for not only the clinical picture but the simultaneous determination of the basal metabolic rate and the fasting blood iodine enables one in a definite way to differentiate between these two diseases and to detect the presence of hypothyroidism. The test is of especial value for the determination of atypical hypothyroid forms, for which the clinical picture, the determination of fasting blood iodine or the examination of the basal metabolic rate do not give sufficient grounds for the diagnosis of hypothyroidism. In all subjects showing a decreased basal metabolic rate the negative results of the test exclude thyroid insufficiency.

**Fat Tolerance Test in Pituitary Disease**—Goldzicher and his collaborators confirm the presence of a fat metabolism hormone of the anterior lobe of the pituitary, which causes a rise of the acetone bodies of the blood. A similar rise of blood acetone after intake of a fat meal seems to denote the physiologic discharge of the fat metabolism hormone. A fat tolerance test was devised to demonstrate the functional status of the anterior lobe of the pituitary. The test meal consists of 4 ounces of heavy sweet cream, 4 ounces of milk, 1 ounce of butter and two slices of toast. Examination of 109 cases after a test meal showed absence of the physiologic rise of blood acetone bodies in fifty-six cases, which consisted almost exclusively of those of pituitary deficiency. A rise was obtained in the normal controls, in all other endocrinopathies and also in some hypopituitary patients. The physiologic reaction was obtained in those hypopituitary patients who had been under specific organotherapy over a prolonged period. Analysis of the forty-two cases in which the blood acetone content dropped after a test fat meal showed a low specific dynamic action averaging 63 per cent, the blood uric acid in these cases averaged 39 mg per cent. The consistent combination of a low specific dynamic action, high uric acid and increased fat tolerance appears to characterize pituitary insufficiency. Preliminary studies suggest that the determination of oxybutyric acid instead of the total acetone content is likely to improve the results of the fat tolerance test. The relation of the fat metabolism hormone to the thyrotropic hormone is discussed and the distinct identity of the two principles is emphasized.

**Sex Determination Test of Dorn and Sugarman**—In determining the validity of the Dorn and Sugarman test for prophesying the sex of the unborn fetus, Murphy and De Renyi injected (intravenously) urine from fifty-one women in the last two months of pregnancy into the same number of male rabbits approximately 3 months of age. Gross and microscopic examination of testicles removed both before and after treatment gave the following results: 1 The urine injection had no appreciable effect on the gross appearance of the testicles, the diameters of the seminiferous tubules or the number of different kinds of germinal epithelial cells. 2 In an insignificant number of instances the treatment may have initiated or increased spermatogenic activity. 3 The testicles of animals treated with urine from women who later were found to have given birth to female children exhibited the same microscopic picture as the testicles from animals treated with urine from women who had later given birth to male children. From these observations it is concluded that the urine of pregnant women does not offer a means for predicting the sex of the unborn child by the rabbit testicle reaction. The use of the testicle reaction for determining the existence of pregnancy in the human being would also seem to be of little if any value.

**Fate of Bilirubin in Small Intestine**—Since there was no loss of bilirubin from the jejunal loop and no loss of bilirubin when pigment was incubated with juice from the loop segment or juice from the entire small intestine, Sackey and his associates conclude that the intestinal juice alone has no effect in converting bilirubin to urobilin during a period of two hours and that in the jejunal loop there was no absorption of pigment or no conversion to urobilin. The experiments, on dogs, showing loss of pigment in the entire intestinal tract suggest that in some place other than the jejunal portion of the intestine the combined activity of intestinal contents and intestinal cells does affect the bilirubin in the intestine. Whether the loss of bile pigment under such circumstances is due entirely to conversion, to conversion and absorption, or to absorption of bilirubin as such remains to be answered.

**Vaccination Against Psittacosis**—The results of the work of Rivers and Schwenker indicate that, when psittacosis virus produces a pneumonia in man, its portal of entry is the upper respiratory tract. The fact is plain that man is unlikely to contract psittacosis pneumonia as the result of the subcutaneous or intramuscular introduction of active virus. It is not known whether the persons who have received repeated intramuscular injections of active virus possess an increased resistance to psittacosis in addition to the neutralizing antibodies in their serums and, if they do possess such a heightened resistance, there is no evidence in regard to the length of time they will retain it. In view of the results that they obtained with monkeys, they believe that one is justified in assuming that a certain degree of protection against psittacosis was afforded the human volunteers by means of vaccination. Monkeys that have recovered from psittacosis pneumonia have an increased resistance to infection with the virus and possess neutralizing antibodies in their serums. Large amounts of active psittacosis virus can be introduced intravenously and intramuscularly into monkeys without the production of a serious infection, such as pneumonia. Relatively small amounts of virus introduced intratracheally into monkeys usually lead to psittacosis pneumonia. Monkeys vaccinated intramuscularly with unattenuated psittacosis virus have an increased resistance to the active agent and possess neutralizing antibodies in their serums.

**Elimination of Brucella Abortus with the Milk of "Carrier" Cows**—Thompson examined the milk of ten high producing cows that never manifested clinical symptoms of infectious abortion but whose blood serum showed agglutinins for Brucella abortus in dilutions of from 1:50 to 1:500 for the presence of Brucella abortus at intervals of thirty days over an entire lactation period by both the direct petri plate method and inoculation of guinea-pigs. The results indicate that inoculation of guinea-pigs is slightly more efficient than the direct petri plate method of examining milk for the detection of Brucella abortus. The results further demonstrate that Brucella abortus may be constantly eliminated with the milk of cows classified as "healthy carriers."

**Immunization with Tetanus Toxoid**—Bergey observed that alum precipitated tetanus toxoid induces, in a dose of 1 cc, a higher degree of immunity than three doses of the toxoid without alum. The tetanus toxoid is of value only as a prophylactic agent against tetanus infection. It has no therapeutic value in persons who are infected with tetanus bacilli. Active immunization against tetanus infection should be carried out as follows: A primary stimulus is given by injecting a dose of 1 cc of the toxoid, this is followed by a rest period of three months, and then a secondary stimulus of 1 cc of toxoid is given. On injury, a third dose of 1 cc of the toxoid is given.

**Dissociation of Streptococci Obtained from Acute Rheumatic Fever**—Howell and Burton endeavored to dissociate the freshly isolated strains of streptococci obtained by blood culture from four patients during acute attacks of rheumatic fever. The four strains were not in the same group according to bacteriologic classification. On blood agar, two of the four strains (102 and 109) were nonhemolytic, one (107) was hemolytic, and one (108), green producing. The nonhemolytic strains grew in broth with uniform turbidity, the others grew with granular sediment. The four strains could not be classified by immunologic methods. Rabbits were immunized with each of the four bacterial strains, and the resulting immune sera were treated for agglutinins, opsonins and complement fixation antibodies. The four freshly isolated strains of streptococci remained virulent, smooth and stable for eight months in spite of efforts to incite dissociation by chemical and physical means and by inoculation of animals. Elements of dissociation in the strains are suggested by pleomorphism and by occasional S-R colonies. The experiments with animals suggest little possibility of changing a smooth virulent strain to a rough

avirulent strain in vivo. Accepting the definition that dissociation is a permanent change that takes place in a bacterium and is then transmitted to subsequent generations, the authors have so far been unable to dissociate the four strains of streptococci obtained by blood culture from patients with acute rheumatic fever.

**Protective Action of Sodium Thiocyanate Against Dysentery Toxin (Shiga)**—Reid and his associates investigated the accidental discovery by Reid and Stubblefield and Crandall and Anderson that dogs which had received thiocyanate from four to five weeks previously failed to react in the usual manner after receiving lethal doses of Shiga dysentery bacillus filtrate. They found that the intravenous (20 mg per kilogram of weight) or oral (60 mg per kilogram of weight) administration of sodium thiocyanate from fourteen days to several (four or five) weeks prior to the administration of a toxic filtrate of Shiga dysentery bacilli affords protection against the lethal action of the filtrate in some but not in all dogs. They can offer no explanation. They did not obtain any protection in rabbits.

**Prevention of Initial Loss of Weight in the New-Born**—Halpern confirms the contention of Kugelmass and his collaborators that hydrating solution reduces the initial loss of weight. In seventy-five new-born infants who received a

hydrating solution for from one to four days after birth the reduction amounted to 394 per cent, and to 368 per cent in thirty-four infants who received it for the first two days of life. Birth weight was recovered on an average of from 13 to 15 days earlier in the treated infants than in a group of seventy-five controls. An average intake of 11 per cent of the solution per birth weight, affording an average of 161 calories, was obtained on the second day of life. A slight benefit resulted from the administration of the solution on the subsequent progress, particularly striking in those infants who received the solution for the first two days only. The administration of the solution for the first two days of life yielded better results from the standpoint of reduction of initial loss of weight, recovery of birth weight and effect on subsequent progress than when it was given for the first three days, the first day or the first four days.

**Huge Tension Cavity in Primary Tuberculosis**—Sanes and Kenny report a case of primary pulmonary tuberculosis in a Negro infant, aged 10 months, the pathologic features of which—cavitation, bronchogenic spread and absence of acute miliary dissemination—resembled those of postprimary tuberculous infection. The primary cavity was of singularly large size. Clinically, the cavity showed distinct tympany.

**Lymphatic Leukemia Resembling Rheumatic Fever**—Sutton and Bosworth describe a case of lymphatic leukemia that draws attention to the fact that joint symptoms may be a prominent part of the picture of acute leukemia in children and emphasizes the fact that the absence of evidence of acute carditis in the presence of polyarthritides in a child less than 3 years of age is presumptive evidence that the carditis is not rheumatic in origin. In their case recurrent joint symptoms masked the true nature of the disease for six months during two admissions to the ward and persisted throughout the remaining six months of life. The clinical picture was atypical enough to cast doubt on the initial diagnosis of rheumatic fever, for it was felt that in so young a child an extensive and protracted polyarthritides should be accompanied by a severely damaged heart, a factor that was lacking in this instance. The child was admitted three times in the course of one year for pain and swelling of various joints. It was not until the third admission, when a generalized lymphadenopathy was also present, that the diagnosis of acute leukemia was made.

**Colorimetric Test for Renal Function**—Herbst and Baumrucker describe a colorimetric test for renal function using diodrast intravenously. A specimen of urine containing excreted diodrast is diluted to 1,000 cc with tap water, and 0.5 cc is placed in a pyrex test tube and evaporated to dryness. 3 drops of a saturated solution of potassium nitrate is added and again evaporated to dryness, 2 cc of concentrated sulphuric acid is added and the whole is corked and heated. It is then cooled, and water is added and cooled again. It is then shaken with 2 cc of chloroform and compared to a colorimeter. The entire procedure is performed in the same test tube from evaporation to color comparison and does not take more than from seven to ten minutes. The color scale may be made by dissolving 100 mg of iodine in 128.5 cc of chloroform and adding 0.1 cc

of this solution for each 5 per cent, diluting up to 2 cc with chloroform. The acidified iodine chloroform solution has a slightly deeper shade than the plain iodine chloroform solution. This can be corrected by layering a few cubic centimeters of water acidified with sulphuric acid over the iodine chloroform solution. The iodine-chloroform scale, if made in sealed glass ampules, will keep its color for months without changing. This test, unlike the phenolsulphonphthalein test, can be performed on bloody urine. The urine is diluted to 1,000 cc to have it correspond more closely to the phenolsulphonphthalein test.

**Differential Diagnosis Between Torsion of Cord and Epididymitis**—Prehn discusses a diagnostic sign for the differential diagnosis of torsion of the spermatic cord and epididymitis. He illustrates this sign by reporting two cases of torsion in which acute epididymitis was ruled out, as elevation of the scrotum increased the pain and tenderness and did not give relief as it would in acute epididymitis. The swelling of the scrotum by edema frequently makes it difficult to distinguish the testicle from the epididymitis which may accompany torsion, and then the scrotal contents are not differentiated. Tenderness along the cord may be present with epididymitis. Nausea and vomiting with some elevation of temperature may be present in both conditions but are more likely in torsion and are usually more severe. Suspicion should always center on inguinal canal or lower abdominal pain when the scrotal sac on one side or both sides is empty to rule out torsion of the cord. In the undescended testicle, with a tumor in the inguinal canal, the condition calls for surgical intervention. It is more important to differentiate torsion from acute epididymitis in the descended testicle, because the treatment here is usually quite different. The treatment should be surgical. Torsion may be prevented by plastic correction of the undescended testicle before puberty by suturing the organ to the scrotum. After puberty, removal is indicated in the partially descended testicle, owing to the danger of peritoneal injury. In the fully descended testicle if early, the torsion may be untwisted and repaired plastically, otherwise removed.

- \*Fungicidal Treatment of Pruritus Ani C M Creech and C J McGillicuddy—p 63

**Etiology of Thrombo-Anguitis Obliterans**—Gray believes that 1 Thrombo-anguitis obliterans is the end result of an intestinal putrefaction, with resultant toxins in the blood stream having a selective action on the vascular intima. 2 Intensive research into metabolism and blood chemistry will reveal the cause and develop preventive measures for thrombo-anguitis obliterans and probably other vascular diseases. 3

Tobacco and infections are only predisposing factors. In early cases and cases with gangrene of the ends of the toes, medical treatment should be used, while in gangrene with severe involvement amputation is the procedure. In the intermediate group, in which vasospasm is noted as improved, sympathetic ganglionectomy is indicated by the work of others, but the author prefers vaccine treatment. Thrombo-angitis obliterans, angina pectoris, arteriosclerosis, Raynaud's disease, erythromelalgia and sclerodactylia are possibly different from one another only in the distribution and clinical manifestation of the same etiologic disease.

**Treatment of Pruritus Ani**—In pruritus ani, with the area infiltrated, Creech and McGillicuddy swab the area lightly with a 30 per cent solution of salicylic acid in alcohol. This is repeated at intervals of seventy-two hours. The patient is instructed to swab the perianal and pericoccygeal regions freely night and morning with a 1 per cent solution of copper sulphate. The infiltration disappears after a few applications. The salicylic acid solution if lightly applied, causes only moderately severe pain, which lasts but a few minutes. In no case has the copper solution caused irritation.

**Clinical Appraisal of Water Metabolism**—Glassberg states that the minimal water intake compatible with optimal nutrition is more than 2 quarts (liters) a day in temperate climates, in hot weather or during excessive physical exertion more should be ingested to aid the body in the elimination of heat. If considerably greater amounts of water are required under these circumstances, its value may be enhanced by the addition of table salt in physiologic proportion (2 teaspoonfuls to the quart). The minimal water intake in infectious or toxic states should be 3 quarts a day in the absence of contraindications. There is no physiologic reason for limiting the water ingested with meals or that allowed during the course of a reducing cure. If an obese patient fails to lose weight under adequate management faithfully executed the cause should be

sought in water retained in the tissues. Dehydration treatments for disease should not be inaugurated thoughtlessly, nor should they be continued longer than absolutely necessary.

**Pyridium in Gonorrheal Vaginitis in Children**—Brown and his co-workers treated gonorrheal vaginitis in twenty-one children by inserting a vaginal suppository of 0.16 Gm of pyridium in a boroglyceride of gelatin base every night followed by a 500 cc cleansing douche. The solution, 1,500 potassium permanganate was given by way of the Dakin tube under low pressure every morning. Under such a regimen the duration of treatment has been reduced gradually so that with a cooperative family the average treatment extends from four to eight weeks.

**Ketogenic Diet in Chronic Pyuria**—Rector and Wheeler treated fourteen cases of chronic urinary tract infection with the ketogenic diet. Practically all the patients had received more or less intensive therapy previously, with little or only temporary benefit. The diet was instituted only in cases that were essentially afebrile. The average duration of the diet was fifteen days. The urine became sterile in eight of the fourteen cases during the course of the dietary treatment and remained sterile for six months (length of follow-up study). In two cases a satisfactory ketosis could not be produced and sterilization was never effected. They showed demonstrable anatomic deformities of the urinary tract. In two other cases the urine was sterile on discharge from the hospital, but the infection recurred later. These two children resumed a normal diet as soon as the cultures became negative. In no case in which the patient was kept on the diet for a week or longer after the cultures became negative has there been a recurrence. In one case, satisfactory ketosis was not attained in the hospital. Later by using a higher ratio diet and by restricting fluids at home the urine became sterile but the infection recurred four months later. The urine of one patient was sterile on discharge, but he did not return for bacteriologic follow up.

**Clinical Experience with Vitamin D Milks**—Lewis discusses the antirachitic value of various types of vitamin D milk. His observations show that vitamin D milks are effective antirachitic agents and require fewer units to prevent or cure rickets than are necessary in the form of cod liver oil or viosterol. In nine rachitic infants 80 units of crystalline vitamin D incorporated in milk brought about definite healing in one month, whereas 80 units dissolved in oil brought about healing in only three of nine rachitic infants during the same period of observation. These results indicate that the medium of milk allows for better absorption or utilization of the antirachitic vitamin and offer an explanation why vitamin D milks as a group require fewer units than cod liver oil or viosterol to prevent or cure infantile rickets. The administration of vitamin D milks to lactating mothers cannot be relied on to prevent rickets in breast-fed infants. Antirachitic agents will have to be given directly to nursing infants in order to protect them against this nutritional disorder. Vitamin D milk might be given with advantage from infancy to adolescence in order to bring about an optimal phosphorus and calcium retention during the growing period.

**Peptic and Varicose Ulcers**—Riddle shows that varicose ulcers of the leg and peptic ulcers have many features in common—their size, shape, chronicity, multiplicity and tendency to heal and reappear in old or new regions. Supportive treatment of varicose ulcers of the leg has been used effectively for many years, treatment being based on the theory that the stagnant blood is pumped back to the heart. Likewise supportive treatment, with the employment of corsets, has been used for many years in treating peptic ulcers, but the satisfactory results obtained were not explained with reference to the varicose theory. The improved condition was thought to result from relief of the splanchnic pull in visceroprotic and neurotic persons. The author observed that bandaging the abdomen with a 3 in. elastic bandage, in a way similar to bandaging the leg, gave great relief in cases of peptic ulcer. He has also used a 3 in. elastic girdle with good results. He explains this relief on the basis that the stagnant blood is pumped out of the stomach at duodenum back through the liver into the systemic, venous circulation. In this manner a peptic ulcer patient may remain ambulatory. The author has been able to cause varicose ulcers of the leg of a duration of forty years to heal by the proper bandaging and by prescribing the proper amount of exercise. Likewise, a regimen of bandaging the abdomen, sufficient walling along with small frequent meals that keep the stomach pumping, has given relief not only to peptic ulcer patients who have not been operated on but to those who have been unsuccessfully operated on. The author employed this method of treatment in twelve cases, with much relief in all and complete relief in the majority.

**Changes in Blood Sugar Level Associated with Surgical Operations**—The blood sugar level associated with surgical operations, Weddell and Gale found, runs parallel with the clinical condition of the patient. Operations on the upper part of the abdomen round the celiac ganglions are more marked in their effect on the blood sugar level than those more remote from this region, irrespective of their duration. If a high blood sugar level is to be avoided, gentle handling is an essential factor in this neighborhood. In patients who appeared comfortable and relatively free from pain on the day following operation, the blood sugar was found to have reached a lower level than in those who were uncomfortable and in pain. The rise in the amount of the blood sugar level depends far more on the nature of the operation than on its duration. A persistently high blood sugar level is a feature to be expected when the patient is not doing well.

**Intussusception in Adult Caused by Lipoma**—Poston reports a case of acute enteric intussusception involving only the small intestine and caused by a submucous lipoma in a man aged 52 years. Such a tumor is usually not discovered until it causes symptoms or until a laparotomy is performed for some condition of which it may or may not be the cause. Search for a tumor especially in the proximal intestine should be made in all cases of intussusception occurring after infancy, and, conversely, all benign tumors of the alimentary canal should be removed as being potential causes of intussusception. In this patient the tumor projecting into the lumen of the small intestine was nodular, it was attached by a pedicle of fibrous tissue and on section was pale yellow and firm, spherical and about 2 cm in diameter. The mesentery was inflamed and there were definite signs of peritonitis. Histologically the tumor was a pure lipoma.

**Gross Anatomy of Lateral Ventricles**—Realizing that the anatomy of the ventricles in a living brain is somewhat different from that seen at dissection or as a result of injection, Torkildsen correlated casts and dissections of the brain with the roentgenologic pictures of the ventricles after the cerebrospinal fluid has been exchanged for air. He used eleven brains from adults, the patients having died of diseases not connected with the central nervous system. He studied a group of 450 selected sets of ventriculograms and encephalograms and from these he selected thirteen sets, because they illustrated particularly what he considered to be a normal ventricular system. He found that the results of the examination by the two methods correspond well but show that a certain amount of collapse takes place in the preparation of the brains. The lateral ventricles vary to a certain extent in size and form. The greatest variation has been found in the posterior horns, in which the calcarine fissure at times seems to cause obliteration. The posterior horns are not constantly present, and a unilateral absence of a posterior horn can be seen in normal cases. The rest of the lateral ventricle is constantly present but varies within certain limits in size according to the size of the skull and age of the patient. Concerning the form of the lateral ventricles, it has been found that there are normally certain variations of the posterior part of the body. The investigations show that certain of the pictures and casts which previously have been supposed to represent the normal ventricles, illustrate a moderate degree of hydrocephalus.

**Aerocystography**—Ross confirms the value of aerocystography as an aid to diagnosis of intravesical enlargement of the prostate. The disadvantages of cystoscopy in certain cases are reiterated and the simplicity of the air-in-bladder technique is noted. The interpretation of a prostatic shadow is clarified, and the ease with which distinction between simple and malignant prostates may be made is emphasized. New growths of the bladder are also visualized by this procedure and an attempt is made to correlate the aerocystographic appearances (corresponding to the morbid anatomy) with the histologic anatomy of these neoplasms. Reference is made to "median bar" formation, and diagnosis by aerocystography in certain types (trigonal

bars) is described. Cystoscopy is a preferable means of diagnosis in the meatal bar. The existence of median bars should be more widely known.

**Pathogenicity of Yeastlike Fungi.**—While investigating the pathology of paronychia and intertrigo, Connor and McKie isolated, in addition to those strains of *Monilia albicans* reported, several strains of yeastlike organisms which differ from *Monilia albicans* in pathogenicity for rabbits and in fermentative reactions. These appear to be the cause of the inflammatory condition from which they were isolated. The strains studied fall into three groups. Group 1 includes typical *Monilia albicans* from paronychia. Group 2 includes one type culture from a laboratory and one strain, number 10, isolated from a chronic inflammatory patch on the sole of the foot. Group 3 includes two strains isolated from the web of toes one from an interdigital lesion and one from a blood culture. Strains from groups 2 and 3 were nonpathogenic for rabbits and formed acid only in maltose and saccharose. Group 2 formed no mycelium in vitro, though delicate mycelium was present in epithelium of the lesion of origin in the case of strain 10, group 2. Group 3 formed typical mycelium in 1 per cent dextrose agar stab and slide cultures.

Intermittent Nocturnal Rhythm in Course of Scarlet Fever Case P

Duchosal and F Sciclounoff—p 409

Cardiovascular Syphilis with Hemiplegia in Child, Aged 3 V Mikulowski—p 417

**Gallop Rhythm.**—Routier and Van Bogaert studied the heart with gallop rhythm by means of simultaneous electrocardiograms and apical cardiograms. Instead of the usual Marcy button employed in cardiography, the authors preferred a pneumatic cuff. The result differed from that in which Marcy's button was used in that the phase of systolic emptying tends to become negative immediately after the initial positive rise. An inverted tracing is thus not obtained. Three characteristics accompany presystolic gallop with such frequency that they serve to authenticate and determine exactly the mechanism. These three, which were studied in detail, are exaggerations of the auricular wave, lengthening of the a-c interval (the time separating the beginning of auricular systole and that of ventricular systole in the cardiogram), and shortening of ventricular systole. More than 100 cases were studied. The presystolic wave was particularly clear in 97 per cent of the cases of gallop more so than in the normal cardiogram. This enlargement is manifested sometimes by shortening of the P-r interval, sometimes by lengthening of the a-c interval. Lengthening of the a-c interval is frequent in gallop rhythm and was found in 14 per cent of the cases of lengthening of the time of auriculoventricular conduction. In 48 per cent of the cases of r-c lengthening it was independent of auriculoventricular conduction. It refers, therefore, to a retardation of ventricular contraction on the excitation received. Exceptionally, the systole is shortened in gallop rhythm. The term "brachysystole" designates auscultatory shortening of the systole and corresponds to the infrequent case in which the tracing demonstrates this shortening.

**Intravenous Urography for Urogenital Fistulas.**—Some cases of unexpected complications in the course of operations for urogenital fistulas and some postoperative complications led Dobrzaniecki and Grabowski to investigate more exactly and more minutely the urinary apparatus. For this purpose intravenous urography with ropan was employed. Their clinical and urographic observations did not exceed ten cases. All the fistulas were obstetric and resulted from hard labor and appeared either immediately after labor or several days later at the moment of elimination of the slough. In one of their cases, forceps caused a fistula. As a result of their studies it was clear that almost half the patients with fistula are subject to a more or less accentuated disorder of the urinary apparatus, which may be discovered with precision by means of intravenous urography.

Intramammary Angioma E Dahl Iversen—p 431

Intraerianal Pneumatocoele with Personal Observation E Lucinesco and N Falcoianu—p 439

**Arterial Hypotension in Spinal Anesthesia.**—Angelesco and Buzoianu state that the hypotensive action of spinal anesthesia depends on several factors of direct or indirect nature such as the anesthetic substance, the quantity of anesthetic introduced, the level of spinal injection, the diffusibility of the anesthetic liquid with the spinal fluid, and the preexisting condition of the arterial tension. The primary element deter-

ning the spinal anesthetic hypotensive mechanism is the neurovegetative system. The cause of vascular hypotension during and after spinal anesthesia is vegetative hypophony, predominantly sympathetic, which depends on the anesthesia of the medullated nervous elements forming consequently an integral part of the anesthesia. Spinal anesthesia not only paralyzes the motor elements controlling muscular contraction or the sensory elements of the medulla but also paralyzes in different degrees the functions of the vagosympathetic vegetative medullary centers. The variability of the hypotension, conditions of intraspinal injection being equal, depends fundamentally on the variable state of vegetative equilibrium in different patients. The important problem is to find a substance which, injected intraspinally, can have two primary effects, anesthesia and motor paralysis, but without paralytic effects on the vegetative centers of the medulla. Up to the present, neutralization of the latter effects is all that can be done. For this purpose ephedrine is satisfactory.

**Hydatid Cysts of Liver**—Carayannopoulos performed a two stage operation on some of his patients with hydatid cysts rupturing into the biliary tract. This consisted first in attacking the cyst and in a second trial attempting to free the obstruction of the biliary passage. In some patients this order was reversed. He concludes that in the majority of cases in which hydatid cysts of the liver rupture into the biliary tract a combined operation in one or two stages to open the cyst and drain the biliary tract is necessary. Simple drainage of the principal passage with simple marsupialization also effects a number of cures, but especially in cases of infection the combined method is to be preferred.

**Obstruction of Bile Duct by Adenopathies**—Brule and David call attention to a group of cases in which signs of obstruction of the bile duct are the only manifestation of localized adenopathy. These adenopathies are of various nature. They are frequently tuberculous, they may complicate general infections or local inflammations, or they may be primary of indeterminate nature. The rapid recession of icterus after removal of such enlarged glands proves to the authors' satisfaction that the adenopathies are the only cause of biliary obstruction and that the biliary retention is purely mechanical.

\*Areas of Epigastric Pain in Diseases of Stomach G. Pieri—p 1051

Abdominal Fistula Due to Foreign Body G. Rizzo—p 1056

**Epigastric Pain in Diseases of the Stomach**—Pieri studied the sites of maximal epigastric pain on pressure in 504 gastric patients who had postoperative peptic ulcers, gastric ulcer, juxtapyloric ulcer, concomitant gastric and duodenal ulcer and epithelioma. The author maintains that these conditions present a constant topography of pain. In ulcers, circumscribed areas of pain are constantly observed on pressure according to the type of ulcer. In gastric ulcer of the small curvature the pain is localized at the gastric site, in juxtapyloric ulcer at the pyloric duodenal point. The author states that the study of the sites of epigastric pain is no means of determining the possible origin of a gastric epithelioma due to a preexisting benign ulcer of the stomach. In chronic gastritis there is usually pain on pressure limited to the upper part of the epigastrium with variable areas of maximal intensity. In 100 cases of gastric neurosis, twenty-four showed pain neurosis, fifty nine asthenic neurosis and seventeen hypersthenic neurosis. In pain of a neurosis the greatest tenderness was at the celiac point in asthenic forms of neurosis it was inconstant and occurred at various points, while in hypersthenic neurosis pain was constantly localized at the epigastric angle, frequently associated with pain at the site of duodenopyloric junction.

These points of pain (celiac, medio epigastric, gastric, duodenopyloric and gastroyejunal) have been observed by the author in individual cases of gastric disease. He concludes that the appearance of individual areas of pain may represent a valuable sign not to be overlooked in the diagnosis of some gastropathies and especially in ulcer.

\*Means Taken to Impede Regeneration of Periosteum After Costal Resection in Thoracoplasty N. Di Paola—p 361

\*Relation of Scleroderma to Calcium Metabolism B. Paggi—p 371

Splenic Anemia Late Results of Splenectomy A. Zingani—p 384

**Regeneration of Periosteum After Costal Resection in Thoracoplasty**—Di Paola found that the use of the thermocautery in rabbit experimentation delays regeneration of the periosteum. Yet it always presents the danger of destroying the underlying pleura and giving pleural reactions leading to serious complications. He states that, although the thermocautery has been effective, it has no practical value. He was able to impede the regeneration of the rib bone with a silver nitrate pencil. The silver nitrate showed itself to be energetic in fact its caustic action extended up to the pleura, causing a pleural reaction which was well tolerated by the rabbits up to the time of their death 100 days after operation. Muller's fluid was totally unable to stop the regeneration of the bone in the costal periosteum. A strong solution of formaldehyde, 15 or 20 per cent applied for a few minutes responded completely to the purpose. Besides the fact that it impedes the regeneration of the bone it does not harm the pleura.

**Relation of Scleroderma to Calcium Metabolism**—Paggi studied a patient presenting diffuse scleroderma with symptoms of diffusion of the sclerotic process to the deep connective tissues. In addition the patient showed typical signs of deforming arthritis. The calcemia and hypophosphoremia were normal. The calcium metabolism showed a daily retention of calcium equal to 1401 Gm. The urine showed a marked deficiency in calcium. An operation was performed for hyperparathyroidism and a ligature was put on the lower right parathyroid. The patient showed rapid improvement and the calcemia was still normal. The author performed a second operation in which he tied off the two parathyroids on the left. Signs of slight hypoparathyroidism were observed. The calcemia and phosphoremia showed a diminution below normal. The chonaxia was also markedly diminished. The calcium metabolism did not show a significant decrease, the daily retention of calcium came to 1365 Gm. Seventeen days after the second operation the patient was given daily injections of parathyroid extract-Collip for twelve consecutive days in doses of from 20 to 40 units. The calcemia rose to 0.110 Gm per thousand after the twelve days. The calcium metabolism was decreased to 0.051 Gm and the chonaxia returned to normal. The author concludes that the therapeutic value of parathyroidectomy in scleroderma requires confirmation, that the study of calcium and phosphorus metabolism did not demonstrate changes due to hyperparathyroidism, that treatment with parathyroid extract-Collip does not show beneficial results and that during the period of slight hypoparathyroidism the chonaxia diminishes under the influence of parathyroid extract-Collip but gradually rises to normal.

Use of Sensitizing Power of Chlorophyll in Actinic Treatment of Alopecia Areata A. Versari—p 886

\*Oculopharyngeal Reflex A. P. Di Sorrentino—p 891

**Oculopharyngeal Reflex**—Di Sorrentino studied the reflex in a number of patients at the moment of instillation of a medical solution in the conjunctival sac. The reflex consists in a movement of rapid deglutition together with a spontaneous closing of the eyes. The swallowing is not associated with the contraction of the orbicularis muscle of the eyelid. The reflex was found only in a small number of patients, most of whom were children from several months to 13 years of age. The presence or absence of an ocular disease has no influence on the positivity of the sign. The author found that the chemical composition of the substances instilled in the

conjunctival sac likewise had no influence on the reflex. The sign may be produced by touching the bulbar conjunctiva with a common glass spatula. The temperature of the stimulating factor, whether liquid or spatula, is important. The stimulation is greater at lower temperatures than at average or relatively high temperatures. The sections of the stimulated conjunctiva (nasal or temporal) are not significant, only the bulbar part is more sensitive than the palpebral. The few adults demonstrating the reflex showed signs of an extremely parasympathetic condition and of marked hypothyroidism. The author interprets it as a reflex of predominantly vagotonic constitutions. Most cases show a constant hypotonia of the endocrine sympathetic system with a prevalence of the parasympathetic section. The author states in conclusion that the nervous path followed by the centripetal stimulus is the trigeminal, while the centrifugal path taken by the motor impulse is represented by the nerves of deglutition.

- Comparative Studies on Pregnancy Changes in Suprarenals E. Kulka—p. 259
- Hemolytic Methemoglobin Formation in Eclampsia Without Convulsions W. Spitzer—p. 267

**Clinical Aspects of Eclampsia**—Fauvet reviews several opinions about the nature of eclampsia and discusses eight cases. He concludes that the disorder described by Batisweiler, and designated by Fahr as diffuse exudative nephritis, is not always present in case of premature detachment of the correctly placed placenta. He thinks that this disorder develops secondarily in the course of the renal disorder of pregnancy. It may terminate fatally with the clinical signs of renal insufficiency. In two of the cases described by the author, the maximum of urinary elimination, together with pathologically increased blood pressure values, did not develop until about a week after delivery. He thinks that this manifestation is connected with the secondary inflammatory edema of the kidneys and he assumes that, as a result of the compression of the parenchyma, the secretory action of the kidney may be reduced to complete anuria. The organism overcomes the renal compression by a compensatory hypertension. If this regulatory action fails, the administration of fluid in the form of osmotherapy may be a life saving measure. However, this treatment is successful only if its prerequisites are fulfilled threatening anuria as the result of inflammatory or noninflammatory edema of the kidney and lack of compensatory hypertension. In circulatory insufficiency the treatment is not advisable. The author discusses the cause of hypertension developing during the later period of the puerperium. He thinks that it is due to hormone action of the hypophysis-interbrain system and considers the possibility of the development of late eclampsia.

**Diagnosis of Death of Fetus**—Brakemann emphasizes that the position of the mother during roentgenoscopy is of vital importance for the recognition of changes in the cranium and the vertebral column of the fetus. He shows that roentgenoscopy, while the mother is lying on her stomach, discloses the typical changes in the cranium of the dead fetus in only a certain percentage of the cases. It fails completely in a considerable number of cases, even if the fetus has been dead for some time and there is severe maceration. The characteristic sign in the vertebral column likewise is often missing if roentgenoscopy is done while the mother is in the same position. Fetuses that have died in the position of pelvic presentation frequently show neither the cranial nor the vertebral signs.

The lack of the vertebral symptom is due to the abnormal pressure conditions in the uterus, produced by the abdominal position of the mother during roentgenoscopy. This pressure produces an artificial stretching of the fetus. If roentgenoscopy is done while the mother is standing up, these purely external, mechanical influences are eliminated and the typical signs may become roentgenologically demonstrable. Control roentgen exposures of the living fetus while the mother is standing up provide the measure for the diagnostic evaluation of the changes in the dead fetus. The author admits that it is not to be expected that roentgenoscopy in the standing position will always reveal the intra-uterine death of the fetus, however, it gives certain prospects for clearing up the diagnosis in cases in which the roentgenogram made while the mother is lying on her stomach does not reveal the typical changes.

**Demonstration of Syphilis During Pregnancy**—A comparison of the results of the Wassermann reaction with those of the Kiss and Kahn reactions revealed to Kolbe and Szekacs that the two latter reactions are well suited for the examination of pregnant and puerperal women. The tests permit the detection of a latent syphilis more frequently than does the Wassermann reaction. In regard to the specificity they are somewhat inferior to the Wassermann reaction, but as far as sensitivity is concerned they surpass the Wassermann reaction greatly. The technic of these tests is simple and they can be completed in a comparatively short time. They may serve as controls for the Wassermann reaction but may also be used alone, particularly after a thorough anamnesis has been taken and following a careful observation of the symptoms after birth, and when the tests are repeated several times during the puerperium.

**Differential Diagnosis of Silicotuberculosis**—Uehlinger gives the histories and postmortem histologic reports of two patients. The lung of the first one showed, in addition to the milary, caseous pneumonias and the scattered, centrally caseated tubercles, many typical silicotic nodules. The sections showed that the tuberculous foci usually adhere to the flame shaped or roundish silicotic nodules. In the second patient the postmortem examination revealed a combination of silicosis and tuberculosis in such a manner that the clinical manifestations (emaciation, attacks of fever, dyspnea, and so on) were primarily caused by the tuberculous pericarditis and hematogenous tuberculosis of the kidneys and the suprarenals, while the small foci appearing in the thoracic roentgenogram were primarily caused by the silicosis. The author calls attention to the difficulties encountered in the roentgenologic differentiation between silicosis, tuberculosis and silicotuberculosis. He maintains that asymmetry of the pulmonary lesions indicates tuberculosis only in case of bronchogenous and not of hematogenous forms. In mixed cases of tuberculosis and silicosis the localization rules (tuberculosis site of predilection the upper lobes, silicosis the middle lobes) are often broken. It should not be overlooked in these combined cases that the pulmonary roentgenogram may reveal silicotic changes, while the clinical manifestations are caused by extrapulmonary tuberculous foci.

**Cataracts Caused by Rays**—In discussing the pathogenesis of glassblower's cataract, Schlapfer points out that some investigators ascribe it to ultrared rays, while others ascribe it to ultraviolet rays. At first the experimental production of cataract by ultrared rays encountered certain difficulties, but now animal experiments have proved that glassblower's cataract

may be imitated to a certain extent by the application of penetrating ultrared rays. The author concludes from this that the eyes of glassblowers should be protected against the ultrared rays by special glasses. Since solutions of ferrous oxide absorb the ultrared rays, he suggests ferrous oxide glasses and states that these glasses are now in use in certain glass factories. Cobalt glasses likewise furnish protection but are undesirable because they impair the capacity for color differentiation. The author reviews clinical and experimental observations, which indicate the possibility that roentgen rays may cause cataract, and consequently he advises against roentgen treatment of disorders in the region of the eye.

Atorol Resistant Lipase in Serum Following Gastric Resection G. Jorns —p. 1054  
Autoregulation of Fat Metabolism S. Leites —p. 1056

**Hypophyseal Regulatory Mechanism in Carbohydrate Metabolism**—Anselmino and Hoffmann state that following a carbohydrate tolerance test there appears in the blood of healthy persons a substance capable of reducing, in the course of several hours, the glycogen in the liver of rats. The substance is present neither in the blood of fasting persons nor in the blood following tolerance tests with fat or protein. Since the anterior lobe of the hypophysis contains a substance that has the same action on the glycogen content of the liver of rats and which, as far as can be determined, has also the same physical and chemical properties as has the substance found in the blood, it is assumed that the two substances are identical. This assumption was corroborated on hypophysectomized dogs, for, in contradistinction to normal animals, the substance did not appear in their blood after a sugar tolerance test. From the regulatory elimination of the substance following intake of larger quantities of sugar the authors conclude that the process is a hypophyseal regulatory mechanism of the carbohydrate metabolism, resembling that of the fat metabolism, which they identified previously. They designate the active principle as the hormone of the carbohydrate metabolism, which originates in the anterior lobe of the hypophysis for investigations revealed that it is identical with none of the other anterior hypophyseal hormones. The authors further made tests on eight patients with diabetes mellitus and found that the blood of the fasting diabetic patients contains the hypophyseal hormones of the carbohydrate and of the fat metabolisms in high concentration. This seems to prove a serious disturbance in the hypophyseal regulatory mechanism of patients with diabetes mellitus.

**Hypophyseal Hormones of Carbohydrate Metabolism and Fat Metabolism**—Anselmino and Hoffmann describe a method permitting with simple means the separation of the hypophyseal fat metabolism hormone and carbohydrate metabolism hormone. The method takes advantage of the fact that, although both hormones are ultrafiltrable in the neutral reaction, they lose their ultrafiltrability in certain  $pH$  values. It was possible to influence with the separated hormones the hepatic glycogen and the ketone bodies in the blood of rats independent of each other. The purified hypophyseal hormone of the fat metabolism increases the ketone bodies in the blood without influencing the liver glycogen. The purified hypophyseal hormone of the carbohydrate metabolism reduces the glycogen content of the liver without increasing the ketone bodies in the blood.

**Determination of Viscidity of Leukocytes**—Ebergeny suggests a new method for the determination of the viscosity of the leukocytes. He asserts that it is not only simpler but

also avoids certain errors of the original method of Philipsborn. He describes the procedure in detail and stresses as one of its advantages that it dispenses with the use of the rather expensive grated ocular and uses instead Bürker's chamber. If the drop method is used a mathematical reduction is employed but the author considers the immersion method superior. In the latter procedure, the leukocytes can be seen in a larger area and are more evenly distributed. The larger immersion surface of the glass platelet makes possible a better elimination of the unevennesses in the adhesion, which may be caused by impurities. Moreover, the irregular density in the adhesion and the sporadic accumulations, which are occasionally noticed in the immersion procedure, prove that in the viscosity of the leukocytes not only differences in numbers play a part but also that there are differences in arrangement. For the observation of this phenomenon of the leukocytes the immersion method is more suitable than the drop preparation.

Idem E. Bergmann —p. 937  
Disease and Death Following Bronchography F. Lickint and Hippe —p. 937  
Observations on Immunity on Basis of Studies on Malaria E. Martini —p. 939

**Treatment by Jejunal Tube in Gastric Ulcer**—Misske and Scholtz state that the treatment by means of the jejunal tube in its present form goes back to Hemming, who took up Emhorn's thought of feeding by means of the duodenal tube. Hemming recommends as the most suitable method the introduction of the tube through the nose. While the patient is lying on the right side, the tube is introduced slowly in the course of a day. The length of the tube is 130 cm. Instead of the rather thick and stiff duodenal tube, the use of a thin elastic rubber tube is recommended. At the end of the tube is an olive of new silver. One of the authors (Scholtz) employed the treatment in thirty-five cases. He found the treatment especially helpful in ulcers of the small curvature. Even deep ulcers of the small curvature yielded to the treatment, as did also rather large ulcers near the cardia. If the tube is in the right position, pain tends to disappear without the use of atropine. In patients with a labile sympathetic nervous system, the injection of the nutritive fluid may at first be accompanied by difficulties but these disorders are caused by sympathetic reflexes and do not necessitate the removal of the tube, if the fluid is at first given in small quantities and slowly. If the disorders persist in spite of this, atropine or a few drops of tincture of opium may be given. Jejunal catarrh is extremely rare in the course of this treatment. Feeding with the jejunal tube is not satisfactory in duodenal ulcers; improvements are not so convincing and it probably does not accomplish more than the ordinary dietary treatment. The authors think that in these cases the tube may even cause an irritation. As a rule it will be easier to carry out the treatment if several patients undergo it at the same time. On the other hand, the treatment is still rather difficult and should be resorted to only if the niche of the ulcer is quite deep, when other treatments are of no avail. The authors give the history of a patient in whom an unusually large niche of the small curvature was nearly entirely obliterated in the course of thirty-five days of treatment with the jejunal tube. They are convinced that no other treatment would have accomplished this in such a short time because the ulcer had proved refractory to dietary and medicinal treatments for several years. Surgical treatment was inadvisable because of the extent and location of the ulcer. The authors do not recommend feeding by means of the jejunal tube for all gastric ulcers but think it advisable particularly for deep ulcers of the small curvature.

**Clinical Aspects of Hydatidiform Mole**—In the years 1923-1932 Sommer observed twenty-two cases of hydatidiform mole in 18,000 deliveries, an incidence of about 1.2 per thousand. Older women seem to have a greater predisposition for this disorder, as the possibilities for the development of a

hydatidiform mole seem to increase with an increasing number of births. Cystic degeneration of the ovaries was found in 50 per cent of the women who developed hydatidiform mole. Excessive elimination of the mammary secretion, a symptom considered by Winter characteristic for hydatidiform mole, was observed in two thirds of the cases. The simultaneous occurrence of myoma and hydatidiform mole was noted in 20 per cent. The incidence of malignant degeneration was 4.5 per cent, compared to 16 per cent in other statistics. The author ascribes this difference to the fact that in his material extirpation of the uterus was done in all the older women. In the cases in which a conservative treatment was employed and which had to be kept under constant observation, the Aschheim-Zondek reaction proved helpful. He thinks that an exploratory curettage should be done as soon as abnormal hemorrhages and other suggestive signs appear.

\*Demonstration of Tubercle Bacilli in Blood B Busson—p 909

Estimation of Resistance of Patient Before Surgical Intervention W Richter—p 910

\*Vomiting of Blood in Tumors of Liver A Beer—p 911

**Etiology of Enteric Disturbances in Children**—Hassmann succeeded in demonstrating the presence of paracolon bacilli in a large number of nurslings and children who had enteric disturbances (dyspepsia, toxicosis, pyuria, icterus simplex). The paracolon bacilli were especially frequent in the children with relapsing intestinal disturbances. The author believes that they have an etiologic significance playing a part in the endogenous as well as ectogenous infections, in the latter so far as bacilli originating in a healthy subject, or bacilli that have become degenerated in the course of a nutritional disturbance become a source of infection for other healthy children. By repeated vaccination in culture mediums paracolon strains could be turned into ordinary colon bacilli, and this makes it appear probable that such a transformation takes place also in the intestine, when after a cure the paracolon bacilli disappear from the feces. On the other hand, it was possible to detect by the culture method a transformation of colon bacilli into paracolon bacilli, which again indicates the possibility of such a mutation in the intestine. Moreover, it appears not only that relations exist between the paracolon group and the colon group but that there is also a relation to the paratyphoid group. The author observed that the paracolon strains from severe enteric disturbances as a rule keep their cultural characteristics longer than do those from the milder disorders or from carriers. The toxic action of the paracolon bacilli was determined by testing the culture filtrates on rabbits, either by intracutaneous injection or by introduction into the intestine. It was found that in the intracutaneous tests the bacterial disturbances have a pronounced effect, causing not only local but also general reactions. Filtrates of the paracolon strains from normal children produced either no reactions or only slight ones. The toxicity of the filtrates seemed to increase with the duration of the incubation. Intracutaneous tests on guinea-pigs proved that on the whole the reaction was the more severe, the more severe had been the intestinal disorder. The toxicity was frequently reduced when the paracolon strain had lost its cultural characteristics, but often the same, when the original strain had kept its cultural properties. Tests on the surviving intestine of rabbits disclosed that filtrates of paracolon strains originating in bacillus carriers had no effect whatever. Filtrates from ordinary colon bacilli (some originating from toxic intestinal disturbances) likewise produced no reaction. Paracolon filtrates from severe enteric disturbances always had a toxic effect on the surviving intestine, for they produced an irritation in low concentration, while they produced paralysis in high concentration.

**Demonstration of Tubercle Bacilli in Blood**—Repeated studies on the demonstration of tubercle bacilli in the blood revealed to Busson that, in spite of identical experimental factors, the development of colonies of tubercle bacilli may differ greatly. This is at least one of the contributing causes of the great differences in the results of tests for tubercle bacilli in the blood. He concludes that either the egg culture medium

(Lowenstein) is not as suitable for the cultivation of the tubercle bacillus as has been believed, at least in certain cases, or that there are certain strains of tubercle bacilli which are extremely easily impaired, so that under certain conditions a suspension in a sodium chloride solution or a passage through the blood stream could damage them. That such differences exist between the various strains is indicated by the fact that cultures of tubercle bacilli from the sputum or from exudates are usually easily obtained by means of the egg culture medium, while cultivation from the blood frequently reveals considerable differences in the growth of certain strains on the several tubes. The author is unable to say whether this is due to the presence in the blood of substances that have a damaging effect on the bacilli or to other causes. At any rate this possibility has induced him to employ the hemolysis by means of saponin, a method that is the least damaging to the bacilli.

**Vomiting of Blood in Tumors of Liver**—Beer describes two cases of hematemesis which he considers worthy of note because they had a pathogenesis that has so far been given little attention. The cases show that hematemesis may result from a compression of the portal vein by a tumor. The hematemesis was caused in both patients by varicose veins on the esophagus, which in turn had resulted from stasis in the portal vein. The first case proves that, with the exception of the ascites, all other symptoms of stasis of the portal vein may be absent. The author ascribes to the incompleteness of the closure of the portal vein or to the short duration of the closure the fact that neither of the patients had a tumor of the spleen. He points out that this seems to be characteristic of the cases in which the stasis is produced by cancer, but he admits that further observations will be necessary to corroborate it. The hematemesis in the terminal stage of the disorder in the first patient may have been caused also by the peptic digestive changes in the esophagus, which result from cachexia and atony.

\*Radiculomeningomyelitis Two Clinical Lectures V Christiansen—p 749

Fracture of Styloid Process of Radius Unsuccessfully Treated. Healing by Means of Prolonged Immobilization O Kapel—p 786

**Radiculomeningomyelitis**—Christiansen states that this disease manifests itself in a spinal type, a cerebral type and a third form representing a combination of successions of the other two, and he describes nine cases. The disturbance is characterized by its acute onset, the rapidity with which the symptoms develop its grave acme and its rapid recovery. In the spinal type, after a short but not constant preliminary stage, with capriciously scattered paresthesias, paralyzes occur of varying extent and varying intensity and kind, usually as paraplegias or quadriplegias, sometimes with hemiplegic or monoplegic distribution, they may be atonic or spastic. Sensory deficiency symptoms are noted and often difficulty in urination. In all cases there are changes in the spinal index. In the cerebral type the basal nerves together with vestibular and cerebellar symptoms dominate the picture. Only three disorders may present differential diagnostic difficulties, namely, cerebrospinal syphilis, in which the biologic examination of serum and spinal fluid are decisive, the milder form of polyneuritis and compression of the spinal cord or of the nervous organs at the base of the brain.

## THE PRACTITIONER OF THE FUTURE

FRANK BILLINGS LECTURE

JAMES B HERRICK, MD  
CHICAGO

Whenever problems of medicine are considered there emerge from the discussion two common factors, the patient and the doctor. This is true whether the problem is that of general practice, state medicine, cost of medical care, contract practice, specialism, health insurance or what not. May it not be assumed that for years to come, perhaps always, there will be disease, and therefore patients and physicians, the duty of the latter to ward off disease when possible to recognize and treat it if it comes, and to ameliorate the evil it causes if a cure cannot be wrought?

He would be rash indeed who would venture to predict what will be the exact status of medicine or the relation between physician and patient a century from now, yes, even a decade ahead. Toppling thrones, scrapped constitutions, unsettled economic conditions, hostile industrial and social groups, angry nations brandishing loaded weapons, all these things not alone upset the world of the present but threaten the tranquillity and stability of the future. Disturbing influences have penetrated into every, even the humblest, walk of life, so that we have a new disorderly literature, a new painting, a new music, a new religion. It need excite no wonder then that medicine has been profoundly affected. In fact, medicine today is in a parlous state of storm and stress.

This applies with special pertinence to the general practitioner. In the last few decades he has had a hard time of it, the family doctor has nearly, or quite, disappeared. Everything seemed to conspire against him. A huge volume of knowledge—bacteriology, x-rays, biochemistry, instruments of precision—suddenly poured in on him and all but overwhelmed him. He was unable to keep up with and to apply this knowledge. Research after the German model became the fashionable fetish, our practitioner developed an inferiority complex perhaps as a reaction to the superiority complex of the all-time research and laboratory worker. He was mortified to learn that the medical school whose cherished diploma graced his office wall had been declared unfit and had disappeared. Specialism rapidly increased, again the doctor felt degraded, for he was but an ordinary, all-round man. Keen economic competition had to be faced from specialists, groups, hospitals, with the cards stacked against him for his erstwhile patients

could, without his help, get prompt and satisfactory service and at moderate fees through telephone, automobile, good roads, and financial aid from the public, or from philanthropic organizations that underwrote hospital and clinic deficits. To cap the climax, the world depression and the pinch of poverty! Well may the practitioner exclaim with the pamphleteer of the American Revolution "These are the times that try men's souls."

Is it to be wondered at that the doctor is discouraged, that his inferiority complex has become more fixed, that he shows signs of a delusion of persecution, that he is in revolt against the old traditions and the threatened formulas of the new practice, that he is resentful and inclined to lay the blame for his debacle on others? He does not realize that his misfortune is in great measure due to uncontrollable forces of the times, that it is partly owing to the inability or failure of his profession early to recognize and adapt itself to the rapid and inevitable changes in social, industrial, economic and medical conditions. Also he does not see that he is clinging to an obsolete ideal, that of the family doctor of fifty or sixty years ago, for whose restoration he clamors. He is incensed at all who seem to be robbing him of any ancient rights and privileges of the doctor of the good old times. And, worst of all, he is blind to the fact that a partial explanation for his present unsatisfactory status lies in himself.

The fault, dear Brutus, is not in our stars,  
But in ourselves, that we are underlings

What are some of his shortcomings? What can be done about it all? This is the main theme of my address, from which I consciously omit a consideration of many important features that are live topics today, e g, economics and social trends. If what I say seems simple, if I utter much that has been said before and speak freely in platitudes, my apologia is that familiarity with truth even though it may not breed contempt may yet breed forgetfulness. Some of these truths need repeating, lest we forget. And as to platitudes, is not John Morley right when he says "Commonplace, after all, is exactly what contains the truth that is indispensable?"

### QUALIFICATIONS FOR SUCCESS

It must be admitted at the outset that we are not able, nor should we try, to restore the old type family doctor. We cannot do this either by resolution of advisory organizations or by edicts of legislative bodies. A new type is evolving. Time will be the active agent in his incarnation. He will not be, he cannot be, the know-all and do-all doctor of the past. This has been well expressed by another "To the brilliant mind of half a century ago a working knowledge of all the departments of medicine was attainable. The general prac-

tioner, competent, efficient was a possibility. "Today such a prodigy is impossible." The term general practitioner in its strict sense implies that the doctor practices at will in all fields. Not only will this not be possible as in the past it will surely not be permitted. Much of modern surgery, obstetrics and applied medicine demands not only unusual knowledge but expert skill and judgment in the handling of instruments and remedial agents and in the interpretation of laboratory observations. These tasks will not be entrusted to the general practitioner unless he is specially qualified.

What are the qualifications for the success of an average practitioner of medicine, one who is neither the superpractitioner of unusual ability nor the one who is hopelessly of inferior grade? Can the doctor of the future meet these requirements? It is to be understood that in this discussion I am concerned only with the so-called general practitioner, not with the specialist, the research worker, the teacher, the medical author.

Whether a physician is to be successful depends in a measure on his native endowment and to some extent on chance. Some men are by nature or inheritance better equipped than others, they have an advantage in physique, mentality, personality, ability to get along with and manage people. While chance and opportunity usually play a relatively unimportant part, we know how illness in the doctor's family or financial loss may destroy hopes and lead to failure. In the long run, however, the factors that determine success are character, a capacity for hard work, knowledge of medical science and the ability properly to apply this knowledge in the recognition and treatment of disease.

What we call character—integrity, sincerity, affability, knowledge of human nature, forcefulness—has a weighty influence in determining one's success.

It seems almost puerile to speak of hard work as an essential, every one admits its value. Yet over and over again we hear doctors bemoaning their fate while all they are doing is to sit around, Micawber-like, waiting for something to turn up. The successful rival is getting ahead, not through luck or influence but through work. He is hunting for something to do and finding it, in the library, laboratory, ward or patient's home. In the medical society he is not concerned so much with pulling wires or trying to unearth some ethical flaw in the conduct of his colleagues as in listening to the scientific program or, better still, taking part in it. I myself have never known a successful doctor who was not a hard worker. When I once asked Dr. Billings what was the important essential for success in practice he replied promptly "hard work." The same idea is set forth by Osler in his charming essay on *The Master Word in Medicine*.

A medical man must have knowledge of his subject. He acquires this knowledge through his teachers, the library, the medical journal, the medical society, the laboratory, the bedside, the morgue. He must look for the new in monographs and original articles. One case well studied at the bedside, with search of the literature, with critical examination of intra vitam or postmortem specimens, with experimental investigation of some of the points involved with carefully written report will do much to clarify the doctor's knowledge, may help clarify for some one else. It does more it will lead to further study along cognate lines, will make him especially proficient in some particular phase of medicine. He learns the meaning of thoroughness. He is working according to the principle of majoring, as the

expression is used in the literary and arts courses in the undergraduate school, a principle that should be more in vogue in medical schools and that should be sedulously followed by every practitioner throughout his whole career. An acute observer in another field—that of librarianship—has well expressed this thought. "The very fact of intensive study of a small topic keeps you in touch with methods and men, and is an admirable corrective to the scattering tendencies of our calling."<sup>1</sup> To spread oneself thin over all fields conduces to mediocrity. A mediocre doctor is a dangerous man in that he does not know his own limitations or the risks and limitations of operative procedures, of drug therapy, of special methods of laboratory and instrumental diagnosis. Mastery of a few subjects by concentrated study means greater efficiency in every respect. *Non multa sed multum* is as true today as when uttered by Pliny or repeated by Roger Ascham. He must get away from the standard textbook style of study, learn how to dig out knowledge for himself, how to evaluate what has been written or spoken. He must lose what has been called the deep and rather pathetic respect for the printed word. He must learn how to think and how to decide for himself.

But the possessor of knowledge, even though it is accurate and encyclopedic, is not necessarily a good practitioner. Such a one must be able properly to use this knowledge, must know the art of medicine. This is a truism, stressed again and again by writers. Yet many a physician wonders why after years of study he is a failure as a practitioner. The reason may go back to the man's choice of a vocation. Some men are not medically minded. They are not fitted and cannot be made fitted for practice, just as some individuals cannot be made into good artists or good cabinet makers. Parents, school advisers and medical school examiners are at times to blame for encouraging or permitting a young man to go into or continue in the study of medicine when his bent and qualifications manifestly point in other directions—toward business, journalism, botany, engineering.

#### RESEARCH VERSUS PRACTICE

There are those who think that success as a practitioner will come only if much time is devoted in undergraduate and later years to research. There is a strange fascination about research. As Zinsser<sup>2</sup> has said, "there has developed a curious halo about research which has exalted it above other and, in the absence of talent, more useful and less expensive methods of occupying time." There should be no quarrel with research per se. There is no higher type of work. It is the activating, catalyzing agent in the science of medicine. Without laboratory experimental research medical science will stagnate and the art of medicine will revert to its old status of empiricism. Yet many research men or, should I say, many men who are working in research laboratories or wards, become poor practitioners. Is this in spite of research or because of it? Some of these men when they start to practice are unable to get down to the level of the everyday problems of the sickroom. They are visionary, with the eyes accommodated for distance, they fail to recognize a clinical fact when they meet it face to face or even when they stumble over it. They detour around the fact, get off the track. And the pathos of it all is

<sup>1</sup> Bishop W. W. *The Backs of Books* Baltimore: Williams & Wilkins Company 1926, p. 11.  
<sup>2</sup> Zinsser H. *Science* 74: 397 (Oct. 23) 1931.

that they don't know they have lost their way. Some of them have a mania for experimentation, they toy with tentative diagnoses, they try new remedial agents that are a priori unsuitable or even dangerous. They are not only inefficient as practical physicians, they are at times a menace to the patient, who after all should not be regarded solely as an experimental animal. Surely research is not the *sine qua non* in the making of a clinician. The spirit and the methods of research? The ability to reason logically? The necessity for control? Emphatically yes. Compulsory research for all? No!

Conversely, the man whose bent and training are in clinical fields does not suddenly become a real investigator because he publishes an article, based on the observations in the hospital ward of himself, his assistants or technicians, even though the article is profusely illustrated with elaborate graphs and tables. Nor does he suddenly become a research man because he spends a few hours a week in a laboratory with test tubes and guinea-pigs. To go through the mechanical and technical procedures according to the directions of the professor, the real investigator whose originality lays out the problem and whose genius guides the investigation, is not a waste of time perhaps, for it may teach something of method, but it does not make a research man out of a practitioner who is lacking in the talent to which Zinsser refers. Good investigators have been spoiled by trying to make practitioners of them. Not a few practitioners have had their heads turned by fancying themselves research workers.

Medical research and practice are two different things. They differ in qualifications of workers, in objectives and in methods. The aim of research, the term being used in its stricter sense, is to advance knowledge by discovery of the new. Practice is the application of knowledge already known. Pure research has often had as by-products results that have been immediately utilizable in the art as contrasted with the science of medicine. Not all the results of observation and investigation by clinicians have been of the so-called practical character. Not a few have had as by-products facts that have had a direct bearing on a better understanding of principles that underlie medicine and cognate sciences. Clinical research, what Sir Thomas Lewis<sup>3</sup> calls progressive medicine, in appropriate institutions or hospitals—such as the Rockefeller Institute—by specially gifted and trained men, who have abundant leisure and suitable equipment, will continue to bring to light basic truths. Research is here a man's life work, his avocation. Investigation by practitioners—curative medicine of Sir Thomas—is in a sense avocational. I believe it will continue to be productive in the future, in spite of the view of Sir Thomas Lewis, expressed in his stimulating and analytical article, that the soil in this field of investigation is practically sterile, its fertility exhausted. There should surely be no heated antagonism between these two groups. There is no reason why, each retaining its autonomy, they should not be companions and allies.

To make it clear that, while not regarding research as essential to the preparation of a man for practice, I yet consider the spirit of research of paramount importance, may I quote with approval from John Livingston Lowes,<sup>4</sup> taking the liberty of substituting

the words "practice" and "practitioner" for "teaching" and "teacher?" He says "The thing is that the spirit of one's expeditions, minor exploits though they may be, into the territory of the unexplored will permeate one's whole attitude toward the body of knowledge handed down from the explorers and the builders of the past. And it will pervade and vitalize one's practice. It is quite on the cards that the results of our personal excursions may never directly enter that practice at all. It is the attitude of mind which they stimulate that is the vital thing. What you know and don't practice permeates and fecundates what you practice." It seems to me that he has aptly expressed an important principle in medicine. Every question of diagnosis is for the clinician a research problem. Unless the physician is inspired by the activating curiosity to know, to find out by close observation, by comparison with his own experience and that of others, by use of laboratory aids or by experiment, he is an inefficient practitioner, non-progressive, and doomed to failure.

#### INDIVIDUALISM IN PRACTICE

I wish to speak of the value of individualism as it applies to the practicing physician, using the term not in a technical sense as referring to a school of philosophy opposed to collectivism but to indicate that which makes one man differ from another, his inherent peculiarity, his individuality, with also an element of independence.

There is today much overstandardization in education as well as in business, politics, social customs. From our schools there is turned out as product a mass of units almost uniformly alike, with the individual ruggedness and earmarks of personal identification worn off. One might think that when a physician escapes from the rigid curriculum of his professional school and enters on his vocation he would be himself. Yet often this is not true. He slips into his place in society and acts as though his job were to keep in line following the rules of the well beaten road, not even stopping to read the signs at the crossroads—simply following as one of the hurrying crowd. Such a course means repression of individuality, the dwarfing of self, the stifling of independent thinking, the loss of initiative and opportunity for constructive leadership, and of that which goes to make life "individual, elastic, thrilling."

The danger, of course, is that in giving free rein to individuality he may go so far as to become not only a radical but a crank. If he so acts as to harm his neighbor, the laws established by society will penalize him. If he violates the rules of right conduct that his colleagues have declared are based on principles of fairness to one another and to those who are ill, he is ostracized by his brother practitioners and perhaps by the community. In other words, as an active member of a learned profession and of society, he must play the game according to certain rules. And that game, the practice of medicine, is not solitaire. We must assume therefore that our doctor is not an extremist.

Take a few examples—perhaps trivial—of what is meant by individualism in practice. Timid young physicians often try to model themselves after some successful physician of outstanding ability. The chances are that, instead of acquiring the solid fundamentals and lofty ideals of their doctor hero, they imitate only externals, acquiring merely mannerisms. Henry Adams recognized this fact when he once wrote to his brother Charles "For God's sake let us go our ways and not

<sup>3</sup> J. Lewis, Sir Thomas, *Observations on Research in Medicine Its Position and Its Needs*, Brit. M. J. 1, 479-483 (March 15) 1930.  
<sup>4</sup> Lowes, J. L., *Teaching and the Spirit of Research*, American Scholar, January, 1933.

try to be like each other." Why should an experienced doctor always have to follow the routine path in arriving at a diagnosis—family history, past history, present complaint? Why not occasionally take a short cut to diagnosis? Not always safe but allowable if, in the vernacular, one can get away with it. Once as an intern I marveled at the accuracy and rapidity of Dr. Christian Fenger's diagnosis of a particular case. He was in a hurry. Ignoring my carefully written history, he pulled down the bed clothes, gave two or three prods in the right iliac region and curtly announced "osteosarcoma of the ilium, inoperable" and walked away. Much learning, wide experience, quick observation, enabled him in sixty seconds to declare a correct diagnosis, prognosis, treatment. This dramatic quick-on-the-trigger work is often effective but is dangerous. Finer and essential diagnostic differences may be brought out only by painstaking examination. Yet the latter method is not without its element of risk. The overcareful man by methods that might be called finicky may permit his first opinion based on plain outstanding facts to be shaken. Some minor point in diagnosis does not fit, its importance is magnified, he hesitates, repeats tests, his conclusions become hazy, perhaps valuable time is lost with serious consequences. In diagnosis judgment, experience, wisdom are at a premium. The physician must individualize and not robot-like follow some ironclad rule.

Why always the stereotyped manner of making a professional visit, which often involves an air of artificiality and unnatural behavior that may well breed lack of confidence on the part of the patient? Why should there be such a binding custom as to the way a doctor tells the patient of the nature of his illness, such stilted formalities as are still occasionally seen at consultations between physicians, or such arbitrary rules as to fees and manner of presenting bills for services? It is well to be reminded once in a while that what is referred to as our Code of Ethics is properly called *The Principles of Ethics*. It is not a code of laws or rules.

There should be more of individuality and less routine in the examination of patients. Some patients need a most thorough examination, perhaps with a prolonged hospital study. Extensive laboratory examinations may be necessary. But, to use extreme illustrations, the patient who goes to the general practitioner or the specialist with a cinder in the eye or an acute diarrhea need not be subjected to an expensive and time-consuming complete examination. Mackenzie cleverly said that if a man goes to a garage because of a punctured tire he resents being asked to pay for having his car thoroughly overhauled and put in repair. The individual physician must be qualified, and therefore permitted, to exercise judgment as to how much is to be done. Even in making periodic examinations, roentgenograms and electrocardiograms may not be necessary every time. The doctor may by these omissions occasionally overlook some hidden disease. On the other hand, the complete examination with its disclosure of numerous inconsequential deviations from the perfectly normal may upset the morale of the patient and start him on a hopeless career of self-centered health introspection, a type with which we are all too familiar. Routine periodic examinations, unless most judiciously made by one who not only knows medicine but knows a good deal of human nature as well, may easily lead, as Allbutt said, to an epidemic of fidgets.

A few months ago a patient said to me as I started to make my examination "I hope you'll not be like the others, I want somebody who will examine me more and the x-ray films less." Not a bad text for a sermon. "Examine the patient more, the films less." The eye, ear, hand of the physician will often reveal more as to the nature of an illness than will the chemistry of the blood, the x-ray film or the electrocardiogram. One frequently learns as much from the way the patient tells his story as from what he tells. One may learn even from what he does not tell, i. e., from what he is evidently concealing. The physician is to recognize that no one of these methods is infallible. Just as the history may be unreliable, the physical examination faulty, so the x-ray technique may be poor, the laboratory test may be only approximately accurate. The eye looking at a film or a terminal laboratory color reaction or at a cell in a high power field may err as may the eye, ear or hand of the clinician. In other words, instruments and methods of precision are not infallibly precise.

Some of us who are older underestimate the importance, or the necessity, even the finality at times, of new instrumental and laboratory tests. But we may still claim a place for the old fashioned history, still a place for the stethoscope. A lesion found by the use of the x-rays may not be the one, as the history would show, that is causing symptoms. The man with a gallstone plainly visible in the film may be suffering from angina pectoris, which the instrument is powerless to disclose. The stone may be quiet, the coronary disease active. The x-rays cannot show a pericardial or pleural friction or a few apical rales that may point suspiciously toward tuberculosis.

I feel, further, that too implicit reliance on laboratory examinations may cause sound clinical judgment to shrivel up from disuse. Besides, unless there is extreme watchfulness the laboratory, as Peabody said of the hospital, may develop the impersonal in the doctor at the expense of the personal. The true physician must possess a dual personality, the scientific toward disease, the human and humane toward the patient. Fortunate is he who has these two ingredients in proper proportions. We may recall that Gibbon was glad he gave up the rigid demonstrations of mathematics before his mind had been hardened. And Jebb<sup>5</sup> recognized the danger that specialism—the overscientific attitude of mind—may destroy such things as humanism and morality.

How are physicians to be so trained that they may become skilled in reaching logical conclusions and wise in judgment as to what to do? The physician learns by study, he becomes proficient by experience. He profits by his own mistakes and those of others. The patient, be he alive or dead, is the most valuable textbook for the undergraduate student and the graduate doctor. "Practitioners are made at the bedside," said Allbutt. "Outpatient departments and the wards are the best clinical laboratories for the future practitioner," says Dean C. F. Martin of McGill. "Pathology is the mistress of us all," wrote Neusser. "To study the phenomena of disease without books," said Osler, "is to sail an uncharted sea, while to study books without patients is not to go to sea at all."

So I make a plea that the physician retain his individuality, believing that thus his life will be fuller, happier and more fruitful.

## NEED OF PERSONAL EFFORT

Are we to judge from the shortcomings of many of our practitioners of today that the outlook is discouraging? Not at all. There are signs of a reawakening on the part of the profession and of society at large to the important part to be played by the family doctor. There are many difficulties, but as Dr Thayer told us two years ago, these will settle themselves in time, for at heart all agencies are working toward the same end, the public good. Our lower schools, universities and professional schools are seriously concerned with what is the best preparatory course for the doctor. How may fewer but better doctors be trained? What nonessentials may with advantage be omitted? They are considering whether it is always wise to bunch prospective investigators, specialists and practitioners and to teach all in the same standardized manner. How may the necessary knowledge be learned, how may it be systematized so as to make it available for use? Some physicians are beginning to question whether some of the time spent in giving to the public a pseudo-education in medicine by popular lectures, radio talks, magazine articles may not be more profitably spent in educating themselves. Will not the physician who is competent gain the confidence of the public and serve the public more by what he does than by what he says? If good and efficient service is rendered by the ordinary practitioner as an individual or as a member of a group there will be fewer quacks, fewer cults, fewer semi-charitable organizations supported, or even run, by philanthropically minded laymen or recalcitrant physicians.

George Vincent several years ago stated that three-fourths of the population of this country were treated by general practitioners who have limited appliances, little or no specialization of skill and slight relation to medical services organized in hospitals, dispensaries and clinics. This condition, granting the correctness of Dr Vincent's figures, has already materially improved. There is less inadequate knowledge and less faulty application than there was. The graduate of today, while he may know relatively less than the doctor of fifty years ago is, absolutely, far better informed than his predecessor. The practitioner realizes that he must know still more. He is eager to learn. To use the slang expression, doctors eat up medical meetings. They flock to the section meetings of the American Medical Association, they crowd its marvelous scientific exhibits. They swarm to national and district meetings whether of general or special character. All over the country, clinical weeks and postgraduate courses are arranged with lectures and demonstrations, and the doctors are there. These facts are significant. Doctors go because they feel the need and because they get something out of these meetings of various kinds. If one were to criticize, it would be that the doctor is often in too much of a hurry to get ahead. He is too much concerned with learning facts and technique that may be immediately applied in practice. Krehl<sup>6</sup> laments that the German practitioner of today is too much in a hurry, too concerned with questions of economics, too neglectful of the fundamental sciences that widen his horizon and increase his usefulness. The American doctor is too willing to be taught by others. He cannot learn in this way alone any more than he could in his undergraduate days learn by the didactic

lecture without laboratory and ward training. Our doctors should do more themselves. They must learn to walk alone. The hard work in the local society in order to be most effective should be done more by members and not so much by invited guests. The status of the practitioner will be determined largely by what he himself does rather than by what is done for him by others. What he gets out of practice will be in proportion to what he puts in.

A result of this personal effort on the part of the doctor will be that he will become more self-confident, will lose some of his inferiority complex. His patients will sense this and go to him as of old for advice or for treatment. He will dare of himself to test a knee jerk, to assess at its real value a heart murmur, even to tell whether tonsils should come out or stay. He may possibly be so thorough as to make a rectal examination and courageous enough to pass judgment on the results, thus depriving the consultant of one of his cherished prerogatives and most fruitful sources of income. In fact, he may reach a state where he will begin to wonder what and why is a specialist, what are his qualifications? He may wonder why there should be antagonism between specialists and practitioners, between research and practice. Why not cooperation? For specialism and research are necessities and have come to stay. And so has the practitioner, but only when, as, and if, he is qualified. Nay, the doctor may go further. He may wonder why he should not be a specialist of a new type, a practitioner-specialist whose functions Dr C. G. Jennings<sup>7</sup> prophetically declares will be "(1) personal and household preventive medicine, (2) periodic medical examinations, (3) emergency first aid medicine—the diagnosis and treatment of acute and chronic disease in its incipency." He thus becomes a sort of "visiting internist," perhaps the outpatient visiting doctor of a group, the liaison officer between the home and the hospital, between the home and the consulting room of the specialist. And this function will be his whether he is practicing as an individual or as a member of a clinic or is fitted somewhere into the complicated mechanism of what seems to be impending—over-socialized, or even state, medicine.

Has the doctor the qualifications of character and willingness to work? I am ready to match the medical profession as a whole against any other profession or trade as to character of its members, their industry, their lofty ideals, their fruitful self-forgetful service to humanity.

Yes, there will surely develop in the future—he is already well on his way—and largely through his own efforts a competent practitioner, who with integrity of character, with ideals of medicine as a profession and not a trade, with mind well stored with knowledge, with skill to apply this knowledge in a large proportion of cases of disease, with consciousness of his limitations, with readiness and ability to advise when and where expert help may be obtained, with good judgment and keen powers of observation sharpened by experience at the bedside and at the autopsy table, is worthy to be the family doctor or adviser, with all the traditional privileges and rewards that came from the personal relation of the old time doctor with the family—esteem and high standing in the community, the confidence and affection of his patients.

## FACTORS THAT INFLUENCE RHEUMATIC DISEASE IN CHILDREN

BASED ON A STUDY OF 1200 RHEUMATIC CHILDREN

ALBERT D KAISER, M D

ROCHESTER, N Y

It is rather infrequent for rheumatism to attack a child with well defined uniform symptoms that completely disappear after a definite period of illness. The clinical condition termed rheumatism is more likely to be insidious in its onset and to produce symptoms that may be mild or severe, of short or long duration, which make it difficult and impossible for the physician to prophesy accurately what the future has in store for a child once stigmatized with rheumatism.

Recurrences of the same type or different manifestations of rheumatism frequently occur. They may not be serious but are likely to cause some disability. If the heart is involved, the initial or the recurrent attacks assume a real menace to the child.

Until the specific cause of rheumatism is known and the constitutional susceptibility of the human host is understood, one can profitably study the factors that may be associated with the primary and recurrent manifestations of this disease in children. An analysis of these factors may show that they bear some relationship to the so-called rheumatic state.

No longer can one limit a discussion of rheumatism to such children who present the well defined symptoms of rheumatic fever, chorea and heart disease. The rheumatic child may show numerous other symptoms of great significance that cannot be grouped in this triad of well recognized symptoms. Pallor, fatigue, anorexia, epistaxis, vague pains and the like frequently are the only evidences of a rheumatic infection in a child. It cannot be stated positively that children presenting one or more of these complaints at a single period are stigmatized with rheumatism. Similar complaints may be associated with some other disease in some instances. The progress of their development may determine their significance. In this study the symptoms assumed to be associated with the rheumatic child have been listed and an effort has been made to detect the exciting factors that may or may not have influenced the return or the prolongation of the rheumatic complaints. Especial stress has been placed on the infections preceding the rheumatic symptoms.

A statistical analysis of the various manifestations noted in more than 1,200 rheumatic children reveals a variety of clinical symptoms. Some children have six or more rheumatic symptoms, while others show only a few definite complaints. Such rheumatic manifestations as pancarditis and rheumatic nodules denote a serious form of rheumatic infection, while the complaints of tonsillitis, pallor and anorexia may be an indication of less serious rheumatic infection.

For convenience, the rheumatic manifestations noted in these children have been grouped as major or as minor manifestations. Both mild and severe manifestations may exist in the same child.

In chart 1 it is noted that pancarditis, a term used to cover the various anatomic lesions of the heart that might be found in rheumatic children, is the most

common major complaint in children stigmatized with rheumatic disease. In the course of the rheumatic infection the heart became involved in 64 per cent of the 1,240 children studied. Not all these children showed evidence of cardiac involvement during the initial attack of rheumatic disease. In a small number the signs of cardiac disease were not noted until after the first or second recurrence of the disease. The high incidence of pancarditis stresses the seriousness of rheumatic disease in children. This rate is no higher than the incidence noted in other clinics, notably those in England.

Acute arthritis or rheumatic fever was the second most common rheumatic manifestation. Rheumatic fever in children is usually accompanied by a fever and painful joints. This type of arthritis, which is termed severe arthritis, occurred in 39 per cent of the rheumatic group. The mild form of acute arthritis not associated with swelling and visible inflammation is termed joint pains. About 32 per cent of the children had complained of joint pains. Combining the mild and the severe forms of acute arthritis in these 1,240 children, it developed that in 71 per cent of the rheumatic children the joints were involved. This is in accord with the accepted view, namely, that arthritis is the manifestation of rheumatism which is looked on as the most characteristic.

Assuming that chorea is in the vast majority of cases due to a rheumatic infection, it was found to occur in 29 per cent of the group. The age and the seasonal incidence were practically identical with that noted in arthritis. In this series, as in other reported series, the disease was found more frequently in girls. Among the 344 children who had chorea, 56 per cent occurred in girls and 44 per cent in boys. Chorea and arthritis

Chart 1—Incidence of the major rheumatic manifestations in 1240 rheumatic children

occurred in the same individual at the same time in only a few instances. Chorea is not so frequently accompanied by disease of the heart as is arthritis.

Muscular rheumatism, or "growing pains," is a rheumatic manifestation subjected to much criticism. That such symptoms do occur in rheumatic individuals is now quite generally recognized. Recently Seham<sup>1</sup> has strengthened the contention that so-called growing pains are usually evidence of inflammatory reaction in the muscles. He feels, however, that "growing pains" is a misnomer and recommends the term muscular rheumatism. In this group 18 per cent of the children

Read before the Section on Pediatrics at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 14, 1934.

Because of lack of space this article is abbreviated in THE JOURNAL. The complete article appears in the Transactions of the Section and in the author's reprints.

1 Seham, Max and Hilbert, Edith. Muscular Rheumatism in Childhood. *Am J Dis Child* 46:826 (Oct) 1933.

gave evidence of chronic pains in the muscles. These children generally have a less severe type of rheumatic involvement and show a lower incidence of cardiac involvement.

The other major rheumatic manifestations occurred infrequently in this series. Rheumatic pneumonia and rheumatic pleurisy are perhaps not always recognized

Chart 2—Incidence of the minor rheumatic manifestations in 1,240 rheumatic children

and for that reason the incidence is low. Erythema nodosum was diagnosed in twenty-four cases, but it is quite likely that at least one half of this number may have been of tuberculous origin. Rheumatic nodules and purpura were found only a few times. Findlay<sup>2</sup> describes the subcutaneous nodule as the least frequent manifestation of the infection. In spite of that statement it was found in 10 per cent of his 701 cases, while in Rochester it was found in only 1.3 per cent of 1,240 rheumatic children. It is generally believed that this manifestation varies in different regions and this may account for the low incidence in this group.

There can be very little doubt of the relationship of these major manifestations to the disease termed rheumatism. When one attempts to enumerate the milder manifestations noted in chart 2 as symptoms recognized in these definitely diagnosed rheumatic children, it became evident that no one of these manifestations justifies a diagnosis of rheumatism. When, however, they occur in conjunction with some of the major manifestations or a number of the mild ones occur in the same child without the classic rheumatic manifestations, their presence has considerable significance.

Tonsillitis or sore throat, depending on whether the tonsils were in or out at the onset of the rheumatic infection, existed immediately preceding an attack of arthritis, chorea or endocarditis in 43 per cent of the cases. It might be said that the throat infection was the first evidence of rheumatic disease, though it was not termed rheumatic in nature until other manifestations were evident. The acute throat infection noted in these rheumatic children did not differ from throat infections in children in whom rheumatic disease does not develop. It does, however, show the potential danger of tonsillitis.

<sup>2</sup> Findlay, Leonard. *Rheumatic Infections in Childhood*, New York: William Wood & Co. 1932.

About one third of all the rheumatic children showed early evidence of fatigue, anorexia and pallor. Similar complaints are noted in other infections, notably in tuberculosis, but if no evidence of tuberculosis is found either by physical examination, by the tuberculin test or by roentgen examination of the chest, one is justified in suspecting an early rheumatic infection when these complaints exist.

Various observers have mentioned the frequency of epistaxis in rheumatic disease. In this series it occurred in 15 per cent of the 1,240 children. Other complaints, such as cephalgia, abdominal pain, cardiodynia and nausea, were noted in a relatively small percentage of the children.

As long as the diagnosis of rheumatic infection in childhood is made only on the presence of one or more of the major manifestations, the real significance of these minor manifestations must remain uncertain. It seems more than probable, however, that any one or any group of these minor complaints may be evidence of a rheumatic infection, even in the absence of the well known serious manifestations.

Rheumatic disease, though most common in later childhood, does occur in early childhood. In a series of 1,126 rheumatic children, definite evidence of rheumatic disease was found in 33 children under 2 years of age. Various authors report only rare cases under 3 years of age. The age incidence may vary in different parts of the world. After 3 years of age the disease becomes more common, as noted in chart 3, and gradually increases in frequency until the tenth year,

Chart 3—Age incidence of first evidence of rheumatic disease in 1,126 children

which represented the optimal age in this series for the first evidence of rheumatic disease. The incidence declines rapidly after the tenth year and at the fifteenth year is as infrequent as in the early years of childhood.

Findlay,<sup>2</sup> in a study of 321 children with arthritis, found that 7 years represented the most common age

for boys and 10 years for girls. A comparison of the British figures with the Rochester group showed that in England 52 per cent occurred during the seventh to the tenth year, while in this series 50 per cent occurred between the sixth and the tenth year.

Rheumatic manifestations are more frequent in girls than in boys. Out of 1,126 children under observation, 612, or 54 per cent, were girls and 46 per cent were boys. A similar distribution was reported in England.<sup>2</sup> A preponderance of girls was reported by Wilson, Lingg and Croxford<sup>3</sup> in a total of 500 children with rheumatic heart disease (60 per cent girls and 40 per cent boys). There is no known reason why the disease is more common in girls, unless it is due to the preponderance of chorea in girls.

It has been generally assumed that rheumatic infection is more prevalent in the winter months. It undoubtedly is influenced by season, though it occurs at any time of the year. As noted in chart 4 the disease in Rochester is more prevalent in the late winter and spring months, which has been the experience of other observers in the United States. In England it is most prevalent during the autumn and winter months. Everywhere it is least common during the summer. This seasonal behavior suggests the possibility of a predilection for certain geographic areas, and such is known to be the case.

Numerous investigations have been made on the social distribution of the disease. Great stress has been placed on the fact that it is primarily a disease of the

this series of more than 1,200 rheumatic children, the Italians contributed the largest number. Poor housing, notably dampness, was noted in many of these homes, but no definite conclusion could be arrived at as to the housing situation as a contributing factor to the etiology of rheumatism.

The initial rheumatic manifestation has considerable to do with the immediate outcome as well as with the course of this disease. Various combinations of rheu-

TABLE 1—Frequency of the Initial Rheumatic Manifestations in 1,181 Children

Incidence of carditis	100%	

matic manifestations are listed. It will be noted in table 1 that the well defined clinical cases can be grouped under the four major headings into which most of the children with rheumatic disease can be placed. They are acute arthritis, including the children with rheumatic fever and joint pains, chorea, muscular rheumatism or growing pains, and primary rheumatic carditis that develops without any of the other recognized manifestations. Arthritis is the most common of the rheumatic manifestations, occurring in 61 per cent of the 1,181 children. Arthritis may occur alone as it did in 28 per cent of the children who had arthritis. In a small number of cases it occurred in conjunction with chorea. It is well known that acute arthritis is frequently associated with carditis. In 67 per cent of this Rochester group of children, some form of carditis developed with the initial attack of arthritis. The high incidence of carditis in this rheumatic group emphasizes the seriousness of acute arthritis in children.

Chorea either alone or in combination with arthritis occurred in 28 per cent of the 1,181 children. The incidence of carditis in children who had chorea was somewhat lower than in those who had arthritis. However, associated with or following the initial attack of chorea, evidence of cardiac involvement developed in 58 per cent. The mortality rate among the children with chorea and with carditis was considerably lower than among the children who had arthritis and carditis. Muscular rheumatism, because of its vagueness and often mildness, is not easily classified. In this series only undoubted cases of muscular rheumatism or "growing pains" have been included. Only 8 per cent of the entire group were complaining of chronic muscular pains alone, but even in this group carditis was evident in 43 per cent of the children. Undoubtedly, if more cases of this less definite rheumatic manifestation were included, the incidence of cardiac involvement would not be so great. It emphasizes the fact, however, that even mild rheumatic complaints may be the exciting cause of a rheumatic carditis. The mortality in the children with rheumatic carditis following muscular

Chart 4—Seasonal incidence of rheumatic disease in Rochester and of arthritis and chorea in London

better class poor families and that it is rarely seen in children among really well-to-do families. Contrary to these statements, many cases listed in this group occurred in well-to-do families and the great majority occurred in the well-to-do laboring classes. The factor of social standing is probably of less importance than the hygienic conditions surrounding these children. In

3 Wilson May G. Lingg Claire and Croxford Geneva. Tonsillectomy in Its Relation to the Prevention of Rheumatic Heart Disease. Am Heart J 4: 197 (Dec) 1928.

rheumatism was low as compared with those who had rheumatic carditis and arthritis

The term carditis includes all the cases presenting myocarditis, endocarditis and pericarditis. It is used for convenience in discussing the cardiac complications in rheumatic disease. Though rheumatic carditis, as a rule, accompanies or follows an attack of arthritis or chorea, it may, and especially under the guise of endocarditis or pericarditis, be the first manifestation of the rheumatic carditis. Undoubtedly tonsillitis or some other infection may have preceded the cardiac involvement, but no clear history could be obtained in these children. The mortality in this group was about the same as in the group of carditis associated with arthritis.

Though the seriousness of the initial attack of a rheumatic manifestation depends on whether or not the heart is involved, the ultimate outcome is influenced by the factor of whether recurrences of the disease with the same or other manifestations are likely to occur.

In table 2, an analysis is reported of 564 children on whom follow up reports have been available. All these children have been followed for three years, a somewhat smaller number for five years and nearly 200 children for ten years or more.

The first three years after the initial attack was the period of greatest hazard for these rheumatic children. Though the fatality rate of 5 per cent is not high, it is responsible for more than one half of the children who die of their rheumatic infection during the ten year period following the initial manifestation. During the three years, 49 per cent of the children had one or more recurrences of their symptoms. During the first three years the chances of a recurrence are somewhat greater when chorea exists than with arthritis.

TABLE 2—Outcome of Rheumatic Disease Based on a Follow-Up Study of 564 Children\*

Type of Complaint (Initial Attack)	End of 3 Years 564 Children			End of 5 Years 341 Children			End of 10 Years 190 Children		
	Died	Recurrence	No Recurrence	Died	Recurrence	No Recurrence	Died	Recurrence	No Recurrence
Acute arthritis (rheumatic fever)	0	52	50	1	23	32	0	9	13
Arthritis and chorea	0	4	11	0	2	8	0	0	1
Arthritis and carditis	23	135	105	4	65	71	10	20	23

Muscular rheumatism and carditis	1	3	9	0	2	7	0	1	4
Primary rheumatic carditis	6	8	32	0	4	14	0	0	1
Totals	5%	49%	46%	1%	40%	48%	6%	29%	26%

\* Died and recurrence mean death or recurrence since the preceding period.

During the period from three to five years after the initial attack the mortality rate was considerably lower and the number of recurrences somewhat less than during the first three years. However, 40 per cent of the group were still having one or more recurrences.

From five to ten years following the initial attack, something over 5 per cent of the children who survived the five year period died. These fatalities were all in children who had a recurrent attack of arthritis with carditis. The number of children in whom recurrences developed dropped off perceptibly during this period, for

only 25 per cent of the children had any recurrence from the fifth to the tenth year after the initial attack.

A review of these 564 rheumatic children reveals a mortality of 8.2 per cent during the ten years subsequent to the initial attack. Recurrent attacks developed in 49 per cent of the survivors during the first three years and again in 40 per cent during the next two years, while in the next five years only 25 per cent had evidence of any recurrence. It would appear that after five years has passed the prognosis for ultimate

Chart 5—The factor of tonsils present or absent at the initial attack of rheumatic infection in 1101 children

recovery and freedom from recurrences is definitely improved.

The tonsils hold a prominent place among the factors that may influence rheumatic infection in childhood. Some years ago it was assumed that infection in the tonsils was largely responsible for the subsequent manifestations of rheumatism. More recently several observers have shown that the removal of the tonsils following the initial attack of rheumatic fever or chorea did not safeguard the child against recurrences any more than when the tonsils were not removed. These divergent views have left considerable uncertainty in the minds of the physicians as to what course to take in the treatment of the tonsils in a rheumatic child. It is quite generally accepted that there is a relationship between an initial infection in the tonsils and a subsequent rheumatic manifestation. If this is true, there should be a lessened incidence of rheumatic disease in children whose tonsils have been removed. If the first evidence of rheumatic infection develops in children whose tonsils have been removed with the same frequency as in children whose tonsils are still present, no close relationship can be claimed between the tonsils and rheumatism in children. On the other hand, fewer instances of primary rheumatic infections in children whose tonsils have been removed suggests a relationship that may be important. The questions relating to the tonsils that should be answered are: Does the presence or absence of the tonsils influence the severity of the disease as reflected in the mortality rate? Does the presence or absence of the tonsils influence the likelihood of recurrences? An attempt has been made to answer these questions from a study of this group of rheumatic children. In a previous study I<sup>4</sup> have shown

<sup>4</sup> Kaiser, A. D. Children's Tonsils In or Out. Philadelphia: J. B. Lippincott Company, 1932.

that about one third more children, figured on a percentage basis, had their first attack of rheumatism when the tonsils were in than those who had been tonsillectomized. Familiar with the number of children in Rochester whose tonsils have been removed at various age levels, I was able to compute the expected incidence of rheumatic disease among tonsillectomized children in the community. In chart 5 the main mani-

TABLE 3—*The Factor of Tonsils Present or Absent at the Initial Attack of Rheumatic Infection at Various Ages in 1101 Children*

Rheumatic Manifestation	Cases	Tonsils In			Tonsils Out			Expected Number with Tonsils Out		
		2-5 Years	5-10 Years	10-15 Years	2-5 Years	5-10 Years	10-15 Years	2-5 Years	5-10 Years	10-15 Years
Arthritis	183	34	62	20	22	39	3	26	34	
Chorea	141	7	56	20	1	29	28	1	20	24
Muscular rheumatism	67	5	13	13	16	20	1	9	17

Totals	1101	146	358	183	8	168	206	11	172	201

festations of rheumatic disease are noted in the children whose tonsils were in at the time of the initial attack and in those in whom the tonsils had been removed prior to the initial attack. The expected incidence among the tonsillectomized children is also stated. The incidence of acute arthritis or rheumatic fever in the tonsillectomized children was nearly the same as the expected rate. Chorea was slightly more prevalent in the tonsillectomized children than was expected. The same situation was true with the manifestation termed muscular rheumatism or "growing pains." Rheumatic carditis, on the other hand, developed somewhat less frequently in tonsillectomized children than one could reasonably expect. Considering the entire group of 1,093 children, the presence or absence of tonsils made only a slight difference on the frequency of an attack of rheumatism. There was less than 10 per cent advantage for the tonsillectomized group.

When, however, the various age groups were considered it was noted that in children under 10 years of age whose tonsils had been removed a rheumatic manifestation was somewhat less likely to develop, while

TABLE 4—*The Effect of the Tonsils on the Outcome of Rheumatic Infection in 597 Children*

Tonsils	Number	Died	One or More Recurrences	No Recurrence
Remained in	156	13%	46%	41%
Out at initial attack	187	7%	48%	45%
Out after initial attack	254	4%	44%	52%

after 10 years of age there was no appreciable difference in the incidence regardless of the absence or presence of tonsils.

The influence of the presence or absence of the tonsils on the mortality rate as well as the relationship to recurrences was recorded in 597 children. In almost comparable groups the mortality rate was 13 per cent among the children whose tonsils were in and 7 per cent among those whose tonsils were out at the time of the initial attack. This result suggests that the most serious type of rheumatic infection is more likely to occur in children whose tonsils are still present.

As to the effect of the presence or the absence of the tonsils on recurrences, the results in this study agree with the reports made by other observers. Recurrent attacks of rheumatism occurred as frequently in tonsillectomized children as in the untreated ones, at all ages. When the tonsils were removed after the initial attack, the percentage of recurrences was only slightly less than when the tonsils were not removed.

A more careful analysis of the relationship of the presence or absence of tonsils to the various rheumatic manifestations shows that rheumatic fever and rheumatic carditis are somewhat less likely to occur in the tonsillectomized children, while chorea and muscular rheumatism are slightly more prevalent in the tonsillectomized children. Since the mortality rate is greatest in the first group, there seems to be some advantage to the child to have the tonsils out in combating this disease.

In spite of the numerous efforts to associate a streptococcal infection with rheumatic disease, no conclusive evidence is yet available to make this relationship certain. The fact that tonsillitis, which is frequently of streptococcal origin, and scarlet fever frequently precede some rheumatic manifestations suggests that the individual has become sensitized to the streptococcus. Considerable support is given to this contention by skin testing rheumatic children with the hemolytic streptococcus nucleoprotein. Two hundred of these rheumatic

TABLE 5—*Cutaneous Reaction to Hemolytic Streptococcus Nucleoprotein in 200 Children with Definite Rheumatic Infection*

Age Groups	Number Tested	Number Positive	Number Negative	Per Cent Positive
1-3 years	4	3	1	75
3-5 years	5	4	1	80
5-7 years	26	15	11	57.7
7-10 years	69	50	19	72.5
10-13 years	58	40	18	68.9
13-16 years	38	28	10	73.7
Totals	200	149	51	74.5

children were tested with this nucleoprotein and as noted in table 5, showed a high percentage of positive reactions. It was found that for the whole group 75 per cent gave a positive reaction, while in a similar test on a like group who did not show evidence of a rheumatic infection only 32 per cent gave a positive reaction. It was also observed that the degree of reaction was more marked in the rheumatic children.

The seasonal incidence of rheumatic disease following closely the epidemics of sore throat and scarlet fever make it seem more than likely that the presence of streptococci in the individual is a factor in the causation of the initial or a recurrent attack of rheumatic disease.

It is a well known fact that a rheumatic infection is frequently preceded by some infection of the upper respiratory tract. In all the surveys made by careful observers there is agreement that frequent attacks of sore throat or tonsillitis are more common in rheumatic children than in so-called control or nonrheumatic children. The frequency of sore throat attacks prior to rheumatic symptoms varies from 28 per cent determined in Bertrani's<sup>6</sup> studies to 77 per cent reported by Ingberman and Wilson.<sup>7</sup> An attempt was made in this study to determine the type of the preceding infec-

tion and to note the course of the rheumatic disease. Infections of some type prior to the rheumatic manifestations were noted in 810 of the rheumatic children, and of this number 59 per cent gave a history of an attack of tonsillitis or sore throat. All types of rheumatic infection followed tonsillitis, but the more severe manifestations such as arthritis and endocarditis were more likely to follow than were chorea and muscular

TABLE 6—Incidence of the Preceding Infection in the Initial Attack of 810 Rheumatic Children

Preceding Infection	Arthritis (Rheu- matic Fever)	Chorea	Muscular Rheu- matism (Growing Pains)	Carditis	Totals

rheumatism. Tonsillitis was a preceding infection in 66 per cent of the cases of arthritis and in 37 per cent of the cases of chorea. Among the 560 children with carditis in whom a preceding infection was noted, 61 per cent gave a history of tonsillitis immediately preceding the initial attack of rheumatic disease. It is this group in which the highest mortality exists. When one notes the high mortality rate and the high percentage of recurrences in the rheumatic children whose initial infection was a sore throat it becomes evident that tonsillitis may usher in the most serious type of rheumatic infection.

It has been impossible to tabulate the preceding infections in the recurrent attacks of rheumatic infections, but in a small number the same infections,

TABLE 7—Outcome of the Rheumatic Infection in 406 Children at the End of Five Years as Related to the Type of Infection Preceding the Initial Attack

Otitis media	0	0	0	0	0	0	0	0	1	0	4	2

namely, tonsillitis, dental infections, common colds and scarlet fever, were noted in about the same frequency. McCulloch and Irvine-Jones<sup>8</sup> have carefully studied this relationship and have shown that an infection of the upper respiratory tract is quite likely to precede a recrudescence of the rheumatic process.

It appears that infections of the upper respiratory tract, notably pharyngitis and tonsillitis, are a very important factor in the development of rheumatic phenomena. In spite of attempts to give rheumatic children

all the advantages of a good environment with a high standard of living, fresh attacks of rheumatism would develop. In most instances recrudescences occurred after an outbreak of some infection of the upper respiratory tract. Coburn<sup>9</sup> has shown in a study of the rheumatic children at the Pelham Home the significance of respiratory infections on the recrudescence of rheumatic manifestations.

The factors thus far discussed have an influence on the frequency and severity of a rheumatic infection. Undoubtedly there are other factors less clearly understood that may have even a greater influence on the development of this disease. Climatic conditions are thought to have an important bearing on the incidence of this disease. Statistical reports show the rarity of the disease in the tropics and the comparative freedom from symptoms of rheumatic children who are transported to the tropics. The reason for the clinical improvement while in the tropics is not clearly understood.

Another factor that is obviously of importance in determining who will have a rheumatic infection is known as a constitutional susceptibility.

Until the factor of susceptibility is better understood and more definite information is at hand on the etiology of this disease, the control of rheumatic disease will not be mastered.

#### SUMMARY

1 Rheumatic infection is a common complaint in certain sections of the country.

2 It occurs at all ages of childhood but most frequently between the ages of 8 and 10.

3 It occurs most frequently in Rochester during the late winter and spring months.

4 Rheumatic disease in children may manifest itself with mild manifestations such as sore throat, fatigue, anorexia and pallor.

5 No social or economic factors play any significant part in the control of this disease.

6 Rheumatic infection is essentially a chronic disease and tends to recur in more than 50 per cent of the cases.

7 Recurrences of the disease are much less likely to develop five years or more after the initial infection.

8 Rheumatic infection occurs slightly more often in children whose tonsils have not been removed at the time of the initial attack.

9 The mortality rate is nearly 50 per cent less in children whose tonsils had been removed at the time of the initial attack.

10 Recurrent attacks were not lessened in tonsillectomized children or in those who were tonsillectomized after the initial attack.

11 Hemolytic streptococcus nucleoprotein skin tests were positive in 75 per cent of the rheumatic children as compared to 32 per cent of nonrheumatic children.

12 Tonsillitis or sore throat was the preceding infection in 59 per cent of the rheumatic children.

13 The most severe cases of rheumatic infection followed attacks of tonsillitis and dental infections.

14 Respiratory infections are an important factor in causing recrudescences of the rheumatic phenomena.

15 One may assume the existence of some constitutional susceptibility to rheumatism, but no proof of it is available.

## ABSTRACT OF DISCUSSION

DR ALBERT J BELL, Cincinnati In this paper, rheumatism is referred to as the rheumatic state, which is the modern and broader conception of the disease. The author includes in this syndrome the minor manifestations, such as anorexia, epistaxis and muscular pains, together with the more classic symptoms of arthritis, heart disease and chorea. I myself have always objected to the term rheumatic fever, as it implies definitely a specific disease, which I am aware some believe but which has not been proved. The fever cannot always be demonstrated. Dr Kaiser's observations have been similar to those previously made by others, notably the very prominent role which tonsillitis and infections of the upper respiratory tract play in the causation of rheumatic manifestations. He had likewise emphasized the disappointing results of tonsillectomy. I will limit my discussion to the removal of tonsils, to sore throat, to tonsillitis and to the operation in question. I have not seen satisfactory proof that the tonsils have been removed sufficiently early, that is, before the infection has spread to other tissues of the pharynx, nor have I seen statistics that give the ages of the children whose tonsils have been removed. Records of cases in which tonsillectomy has been performed around five years and their subsequent careers followed over a period of years would be desirable. All physicians are in agreement that tonsillitis and infections of the upper respiratory tract are the most frequent causes of rheumatic manifestations. While the operation of tonsillectomy has been very much abused and the results are unsatisfactory, I believe that it is still a very important measure of treatment, but it must be used intelligently and not performed merely because enlarged tonsils are present. The question of allergy and its relation to throat infections must be studied, as well as the relation of other lymphoid tissues in the throat, to infections in the upper respiratory tract. I cannot but feel that a clean throat will predispose less to infections of the upper respiratory tract, which all agree are the principal causes of rheumatic manifestations.

DR JESSE R GERSTLEY, Chicago During the last seven years in studying rheumatism I have concentrated upon one of its supposed manifestations, chorea. At the end of seven years, 150 cases were summarized and forty-five taken as a cross section. Five of six patients with chorea, who had a true history of arthritis and had tonsils, developed endocarditis. There were no cases with a history of rheumatism and no tonsils. In nine questionable cases of rheumatism there were one questionable and four definite cases of endocarditis among those with tonsils. In those patients with a questionable history of rheumatism and no tonsils, only one developed endocarditis, and here the diagnosis was tentative—out of five. Eleven patients with no history of rheumatic infection are those whose tonsils were present. There were two with definite endocarditis and two with questionable endocarditis. In the largest number of patients with chorea, those with no history of rheumatism and no tonsils present, only one out of the fourteen developed endocarditis. Of course, observations of this sort must be repeated with a much larger series. I don't now whether this holds true for most cases. At any rate judging from this series, I would conclude that tonsillectomy is a very important factor in preventing endocarditis in chorea. It also raises the question as to whether chorea is really a manifestation of rheumatic infection.

**Laboratory Data and the Unaided Senses**—Too many practitioners accept the dicta of the laboratories as though they represented some magical contribution to the solution of a given case, whereas laboratory data are frequently of no more importance, and often of less significance, than are facts in the history or observations made on the patient with the unaided senses. It is essential that we should inculcate this view-point into our students and impress upon them the importance of treating laboratory data like any other form of information and of basing their conclusions regarding a given case of disease on a careful analysis of all the pertinent facts and on logical meditation of these facts.—Blumer, George. Some Discursive Remarks on Bedside Diagnosis *Yale J Biol & Med* 6: 571 (July) 1934

## DIABETIC CATARACT

INCIDENCE AND MORPHOLOGY IN 126 YOUNG  
DIABETIC PATIENTS

C S O'BRIEN, MD  
J M MOLSBERRY, MD  
AND  
J H ALLEN, MD  
IOWA CITY

Cataract is a well recognized complication of severe diabetes mellitus in young persons but is considered to be comparatively rare. It is believed by some to occur only in those with associated vascular disease. In its typical form diabetic cataract is described as developing in both eyes with great rapidity, that is, within a few hours or days. There is no evidence of a characteristic morphology, different observers describe subcapsular vacuoles, water slits, and various types of grayish white and iridescent subcapsular and cortical opacities, for example, reticulate, asbestos-like, punctate and flocculent. Also a saucer-like gray and opalescent posterior subcapsular opacity is described.

This study of the crystalline lenses in young diabetic subjects was undertaken in order to determine the incidence and morphology of cataracts in such patients. The report is founded on repeated detailed examinations, with the slit lamp microscope, of the lenses in 126 diabetic patients up to and including the age of 33 years. Most of the patients, when first seen, had been on treatment for some time. Practically every lens in the entire series showed occasional small punctate congenital opacities and there were a few in which coronary cataract was present, the diagnosis in such cases was usually not difficult, but in those lenses in which doubt existed the changes were classified as congenital.

## REPORT OF CASES

CASE 1—M B, a boy, aged 12 years, seen in January 1931, had had uncontrolled severe diabetes over a period of three years and failing vision for three months. The blood sugar was 310 mg per hundred cubic centimeters, and glycosuria was present. Uncorrected vision was 6/60 in the right eye and 6/9+ in the left, with the ophthalmoscope posterior subcapsular opacities were noted in each lens.

In September, countless fine snowflake opacities were discovered in the cortex of the right lens, they were more numerous posteriorly and in one or two areas were grouped into radial striae. A few fine flakes were seen in the nucleus. In the left eye the changes were similar but less advanced. Following linear extraction of the right lens the corrected vision was 6/5.

In April 1932 the cataract in the left eye was more advanced, the snow storm appearance was present throughout the cortex and there were smaller flakes in the nuclear region.

CASE 2—C G, a girl, aged 12 years seen in June 1931, had had uncontrolled severe diabetes over a period of one year. The blood sugar was 350 mg per hundred cubic centimeters and there was glycosuria. The corrected vision in each eye was 6/6, a hyaloid artery remnant was present on the posterior capsule of each lens and there was an occasional punctate congenital opacity.

In December each lens showed a snowstorm appearance, with innumerable grayish and bluish white flaky opacities in the anterior cortex and an even greater number in the posterior cortex. Under the posterior capsule was a thin granular gray saucer-like opacity and here and there in the lens iridescent crystals were noted. The lens sutures and fibers were unusually distinct.

From the Department of Ophthalmology, State University of Iowa College of Medicine.  
Read before the Section on Ophthalmology at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 15, 1934.

CASE 3—A G, a girl, aged 12 years, seen in February 1931, had had poorly controlled severe diabetes over a period of two years. The blood sugar was 300 mg per hundred cubic centimeters despite daily administration of 156 units of insulin, and glycosuria was present. The vision was 6/6 in each eye. The right lens showed a few snowflake cortical opacities and many delicate iridescent crystals in the anterior and posterior subcapsular regions. The left lens was of similar appearance.

needings, the corrected vision in the right eye was 6/9 and in the left 6/5.

CASE 5—L La T, a youth, aged 16, seen in June 1931, had had poorly controlled diabetes over a period of three years. The blood sugar was 318 mg per hundred cubic centimeters and there was glycosuria. The corrected vision was 6/6 in each eye. In the anterior and posterior cortical areas of each lens were many punctate opacities, the exact nature of which

CASE 4—L B, a boy, aged 14 years, seen in July 1928 had had poorly managed diabetes over a period of five years. There was no glycosuria but despite insulin the blood sugar was 170 mg per hundred cubic centimeters. Uncorrected vision was 6/15 in the right eye and 6/30 in the left, early bilateral posterior subcapsular cataracts were noted but were studied only with the ophthalmoscope.

In January 1930 the vision was approximately the same. Snowflake opacities were noted throughout the anterior and posterior cortical areas in each lens and in the posterior subcapsular regions there were confluent opacities. Both lenses were removed by linear extraction and, following subsequent

was indeterminate they may have been congenital or a complication of the diabetes. In the anterior subcapsular areas there were a few finely granular radial striate opacities, which were undoubtedly pathologic.

CASE 6—O P, a youth aged 17, seen in April 1931, had had moderately well controlled diabetes over a period of five years. The blood sugar was 337 mg per hundred cubic centimeters and there was glycosuria. The vision was 6/5 in the right eye and 6/6 in the left. In the right lens were a few fine punctate cortical opacities, while in the posterior subcapsular area fine granular radiating striae were seen. The left lens contained similar but fewer opacities.

## DIABETIC CATARACT—O'BRIEN ET AL

JOUR. A. M. A.  
SEPT. 22, 1934

CASE 7—F F, a girl, aged 18 years, seen in February 1934, had had diabetes over a period of two years. The disease had been under excellent control for six months, but vision had gradually failed over a period of three months. The blood sugar had been 316 mg per hundred cubic centimeters at one time but was within normal limits at the time of ocular examination. Uncorrected vision was 6/60 in each eye. In each lens the entire cortex was filled with myriads of snowflake opacities and there were fine granular opacities and vacuoles in the anterior and posterior subcapsular areas. The posterior subcapsular changes were rather dense and a number of iridescent crystals were present. When seen in March and again in April the cataracts were apparently the same.

CASE 8—W L, a youth aged 19 seen in March 1931 had had poorly controlled severe diabetes over a period of almost three years. The blood sugar was 337 mg per hundred cubic centimeters, and glycosuria was present. The vision was 6/6 in each eye. A few small punctate congenital opacities were found in the anterior cortex of each lens, in the posterior subcapsular region of the right lens were gray granular radial spicules extending into a central granular saucer-like opacity.

CASE 9—W N, a man aged 22 seen in November 1931, had had uncontrolled diabetes over a period of four years. There were a hyperglycemia of 231 mg per hundred cubic centimeters and glycosuria. The corrected vision was 6/12 in the right eye and 6/15 in the left, a reduction principally due to bilateral retinitis. In the anterior and posterior subcapsular areas of each lens were innumerable snowflake opacities which in places were confluent and arranged in radial spicules. A few iridescent opacities were found in the posterior subcapsular region (fig 1). In February and July 1932 no further changes were seen in either lens.

CASE 10—G S, a man aged 22 seen in August 1931 had had symptoms of severe diabetes over a period of four months. The blood sugar was 400 mg per hundred cubic centimeters and there was sugar in the urine. As a result of high compound hyperopic astigmatism and rapid reduction of blood sugar, the uncorrected vision in each eye was 6/21. A few punctate congenital opacities were found in the anterior and posterior cortical regions of each lens. In November 1932 no additional lenticular changes were seen. Uncorrected vision in the right eye was 6/15 and in the left 6/9.

In May 1933 despite a restricted diet and insulin, bilateral cataracts had formed and the vision in each eye was reduced to 1/120. The right lens was swollen, veil-like opacities water slits and opalescent crystals were found under the anterior capsule, while the anterior cortex was filled with large, coarse shimmering opacities, the posterior cortex was invisible. Study of the left lens revealed earlier changes of a similar nature, in the clearer anterior cortical areas were snowflake opacities, which may have been present throughout the entire cortex in the earlier stages. Two months after linear extraction the corrected vision in the right eye was 6/6-1.

In August 1933 the left lens was diffusely gray and swollen. Myriads of confluent gray granules and one large sector opacity were found in the anterior cortex. The lens was similar in appearance to that of a rapidly advancing senile cataract. The corrected vision after linear extraction was 6/6+.

CASE 11—D G, a woman aged 22, seen in August 1931, had had severe uncontrolled diabetes over a period of approximately ten years. Vision had failed gradually for approximately months. Despite a restricted diet and insulin the blood sugar was 273 mg per hundred cubic centimeters and there was glycosuria. The vision in the right eye was 6/12+ and in the left 2/60. In the anterior subcapsular region of the right lens was a thin veil-like disciform clouding, fine opaque radial striae were present in the anterior and posterior cortical areas and between these striae were many snowflake opacities. A diffuse, confluent, granular, saucer-like posterior subcapsular opacity was noted. The left lens was similar but the opacities were more numerous. A linear extraction of the left lens was made and a few months later the corrected vision was 6/6+.

In September 1932 the vision in the right eye was 6/12 and the lens opacities were somewhat more advanced.

CASE 12—J C, a man, aged 23, seen in February 1931, had had poorly controlled severe diabetes over a period of four years, with gradual loss of vision for twenty months. The blood sugar was 289 mg per hundred cubic centimeters, glycosuria was present. Uncorrected vision was 3/60 in each eye. In the right lens were several large, flaky gray opacities immediately beneath the anterior capsule, throughout the anterior cortex were many soft punctate and granular opacities which in places were aggregated to form radiating striae. The lens fibers were unusually distinct and in some areas there were intervening fine linear opacities. In the central posterior subcapsular area was a typical saucer-like opacity composed of confluent gray granules and iridescent crystals, subcapsular spicules extended from the periphery into this central mass. Gray granular opacities were present in the posterior cortex. The left lens was similar in appearance (figs 2 and 3). In March the right lens was extracted, the corrected vision was 6/6. The left lens was extracted in April and the vision with correction was 6/5.

CASE 13—B M, a woman, aged 24 seen in September 1929, had had poorly controlled severe diabetes over a period of five years and failing vision for three months. The blood sugar was 700 mg per hundred cubic centimeters and there was glycosuria. The vision was 3/60 in each eye. Both lenses showed anterior and posterior cortical opacities but unfortunately no detailed description was recorded. The lenses were extracted and the corrected vision in the right eye was 6/5 and in the left 6/6.

CASE 14—L G, a woman, aged 26 seen in October 1930, had had poorly controlled severe diabetes over a period of four years and gradual loss of vision for three years. Blood sugar was 557 mg per hundred cubic centimeters and sugar was found in the urine. The vision was 1/60 in each eye, there were subcapsular opacities in both lenses, but no record of the details was made.

In February 1931 the vision in the right eye was 1/60 and in the left 1/120. In the anterior subcapsular and cortical areas of the right lens were many fine snowflake opacities which were more numerous in the periphery of the lens (fig 4). Similar opacities were present in the posterior cortex and many fine radial spicules composed of confluent flakes extended inward from the periphery. The posterior subcapsular region showed an iridescent irregular saucer-like opacity. The left lens was similar but the changes were more advanced. The right lens was extracted in the capsule and the corrected vision was 6/6+.

In April an extracapsular extraction of the left lens was made, the corrected vision was 6/9.

CASE 15—I S, a woman, aged 27, seen in March 1933, had had moderately well controlled diabetes over a period of eight years. The blood sugar was 362 mg per hundred cubic centimeters and sugar was found in the urine. The vision was 6/6 in the right eye and 6/9 in the left, in the anterior and posterior subcapsular regions of each lens were radial striae composed of fine granular grayish white opacities.

CASE 16—L H, a man, aged 28 seen in September 1927, had had poorly controlled severe diabetes over a period of two years. The blood sugar was 478 mg per hundred cubic centimeters and glycosuria was present. Uncorrected vision was 6/10 in each eye and both lenses appeared normal. In March 1931 corrected vision in each eye was 6/6. There were many punctate opacities and opalescent crystals in the anterior subcapsular region of the right lens, similar but more advanced changes and many small vacuoles were present in the posterior subcapsular area. The left lens had a similar appearance.

CASE 17—S G, a man aged 30 seen in August 1933, had had uncontrolled mild diabetes over a period of thirteen years. Vision had gradually failed for eleven years and a cataract had been removed from the left eye at another hospital in 1932. He had been on insulin. The blood sugar was only 179 mg per hundred cubic centimeters and the urine was normal. The right lens showed many fine punctate opacities in the anterior subcapsular area and radial striae opacities in the anterior cortex. Bluish gray punctate dots were pres-

ent in the perinuclear region. In the posterior subcapsular area was a dense granular saucer-like opacity.

CASE 18—A E, a man, aged 31, seen in June 1931, had had uncontrolled severe diabetes over a period of three years. The blood sugar was 417 mg per hundred cubic centimeters, and the urine contained sugar. The vision was 6/6 in each eye. There were many small grayish white snowflake and punctate opacities in the anterior and posterior cortex of the right lens. The left lens was similar but the flakes and punctate dots were irregular in size and more numerous, especially in the posterior cortex.

Fig 1 (case 9)—Snowflake or snowstorm cataract in lens cortex of right eye high power slit lamp

CASE 19—G B, a man, aged 33, seen in January 1932, had had poorly controlled severe diabetes over a period of four years. The vision had failed gradually over a period of two years and rapidly for one month. The blood sugar was 380 mg per hundred cubic centimeters, and glycosuria was present. Uncorrected vision was 6/12 in each eye. Snowflake opacities were seen in the anterior and posterior cortical areas of the right lens, in the anterior subcapsular region were many fine iridescent crystals, and delicate radiating wedge-shaped spicules lay in the cortex. The left lens was similar but the snowflake opacities were more numerous and there was a gray opalescent granular saucer-like opacity in the posterior subcapsular area.

CASE 20—P E, a man, aged 33, seen in March 1931, had had poorly controlled severe diabetes over a period of nine years. The blood sugar was 665 mg per hundred cubic centimeters, and sugar was found in the urine. The uncorrected vision in the right eye was 6/9 and in the left 6/15. There was evidence of an old iritis in the left eye. In the posterior subcapsular region of the right lens were many radial spicules extending centrally into an irregular gray granular saucer-like subcapsular opacity. There were similar changes in the left lens.

COMMENT

Severe, prolonged, poorly controlled diabetes was present in many of the 126 cases and, with but two exceptions, in twenty cases presenting complicating cataracts. According to the histories, the duration of the general disease, at the time lens opacities were detected varied from one to thirteen years, the average being approximately five years. The severity of the diabetes in patients with cataracts was indicated by the high concentrations of the blood sugars and glycosuria in eighteen of the twenty cases, and the invariable evidences at one time or another of ketonemia and ketonuria. The blood sugars on admission to the hospital, varied from 170 to 700 mg per hundred cubic centimeters the average concentration being 373 mg. Evi-

dences of ketone bodies in the urine were found in every patient, in three cases there was a history of coma. These conditions were present despite attempts to restrict the diet and advice as to the use of insulin, they go to show the difficulties in the home control of diabetes. In many of the patients other pathologic conditions of more or less severity were known to have been present or were discovered at the time of examination, but in no case were they of a type known to cause cataract. Arteriosclerosis was found in only one patient.

A diagnosis of diabetic cataract was made in 20 of the 126 cases, an incidence of 16 per cent. There were thirteen males and seven females affected. The lenses were normal in thirty-one patients under 11 years of age, opacities were present in eight of fifty-eight patients aged from 11 to 20 years inclusive, in nine of thirty-one patients aged from 21 to 30 years inclusive, and in three of six patients aged from 31 to 33 years inclusive. These changes were bilateral, with one exception, in one patient, opacities were just forming in one eye and evidently had not yet begun in the other. It is recognized that diabetic cataract may form and mature within a few days, but the development of lens opacities in the cases herein reported was not extremely rapid, in most instances it was a matter of weeks or months.

Only a small number of lenses had been studied when it was realized that there were two common types of cataract. The more unusual and striking of the two was that designated as snowflake or snowstorm cataract, it appeared first in the anterior and posterior cortical areas, near to but not immediately under the capsule, as innumerable scattered grayish to bluish white flaky opacities. In later stages the opacities occupied the entire cortex. The appearance with the biomicroscope was that of a heavy snowfall against a leaden sky. This snowstorm cataract was seen in twelve cases, an incidence of 60 per cent. It was well developed and typical in ten cases and appeared in slightly atypical form in two cases. There is reason to

Fig 2 (case 12)—Right eye ophthalmoscope

believe that such opacities may have been present in other lenses during early stages of development of the cataract.

The other common type of cataract was a saucer-like posterior subcapsular opacity composed of confluent gray granules and oftentimes containing iridescent crystals. Frequently finely granular, radial, posterior subcapsular striae extended from the equatorial zone toward or into the central opacity. This is not an unusual type of opacity, since it appears following injury in association with certain ocular diseases and occasionally as a senile lens change. It was present in

## DIABETIC CATARACT—O'BRIEN ET AL

JOUR. A.  
SEPT. 27

its typical form in twelve cases and in an atypical form in two cases, an incidence of 70 per cent. Anterior subcapsular opacities were found in eight cases, an incidence of 40 per cent, they were punctate, finely granular or veil-like and occasionally showed iridescent crystals. In some lenses delicate radial striae were present. Iridescent crystals were noted in eight cases, an incidence of 40 per cent. They were usually located in the

Fig. 3 (case 12)—Anterior subcapsular and posterior subcapsular opacities in right eye low power slit lamp

subcapsular areas but in a few lenses were found in the cortex. It is to be understood that more than one type of opacity was present in many lenses and that vacuoles, water splits and lamellar separation were common changes.

## SUMMARY

In a study of the crystalline lenses in 126 young diabetic patients, aged from 2 to 33 years inclusive, the incidence of cataract was 16 per cent. The morphology of these cataracts differed but two common types of lens changes were encountered.

1. Snowflake or snowstorm cataract. This type was found in 60 per cent of cases and appeared as innumerable small grayish white flaky opacities in the anterior and posterior cortical areas. In a routine study of several hundred cataracts it was seen, with one exception, only in persons with diabetes.
2. Posterior subcapsular cataract. This type was found in 70 per cent of cases as a saucer-like posterior subcapsular opacity composed of confluent gray granules and oftentimes iridescent crystals. It is not peculiar to diabetic cataract, since similar changes may follow ocular injury or disease, and it has been noted in senile cataract.

University Hospital

## ABSTRACT OF DISCUSSION

DR. ARNOLD KNAPP, New York. Most ophthalmologists who are connected with eye clinics do not see many of these diabetic cases. The one I recall best is the most recent case that I have seen. A young child presents this posterior cortical opacity and some equatorial cortical changes but none of the anterior subcapsular changes that the authors have described. I wish to emphasize the rarity of the condition and secondly the impossibility of changing the course of these cases by treatment. I should like to ask Dr. O'Brien where in the lens in these snowflake-storm cataracts the process

apparently begins. Has he observed with the slit lamp any of these cases, changes in the posterior layer of the lens in his opinion that by treatment the progress of these cases can in any way be retarded?

DR. SANFORD GIFFORD, Chicago. We are fortunate to hear such a series of cases. The reason we consider this condition so rare is that most ophthalmologists see only the ones that go rapidly on to maturity. In the last two or three years I have seen only two cases that I can remember, of which went on rapidly to maturity. Operations were formed with very good results. I think that is the rule in these cases, that they are not complicated cataracts in ordinary sense, they behave like other types of soft cataracts. I have never seen this snowstorm type of cataract in I have not seen them until later when the whole lens was opaque and one could not tell how they started. From what I understand about the way opacities develop in the lens I think these opacities were once subcapsular and then later the condition would stop and the opacities became deeper as new lens fibers were formed as in the case of parathyroid tetany. Goldschmidt was able to produce attacks of parathyroid tetany in dogs and a layer of opacities would develop. Then there would be clear lens fibers laid down on top of them, and following another attack of tetany another layer of opacities would develop. In this condition, diabetes, this is going on all time, so as new lens fibers are formed, opacities are developed in these new layers. This posterior subcapsular type of cataract is a mixed up question. For instance, this type is usually referred to as cataract complicata but the posterior, saucer-shape cortical cataract resembles it which is a very common form of senile cataract. The cataract complicata comes forward in the lens and, starting under the anterior capsule, goes back into the lens. This looks like a picture of ordinary posterior saucer-shape cortical cataract which is seen as a form of senile cataract but I know it does occur in young people because I have seen it in one family in which every member developed this type of cataract at a very early age.

DR. EDWARD BLAUW, Buffalo. The giving of a new name for this form of cataract does not have my sympathy. As I understand the speaker it is a form of cataract punctiformis corticalis. Such forms can be congenital and acquired. The

Fig. 4 (case 14)—Snowflake or snowstorm cataract in lens cortex high power slit lamp

origin of such opacities does not need to be directly under the capsule. The small bubbles found in posterior saucer-like cataract are not exudates. Some form of posterior saucer-shape cataract seems to be congenital if not acquired in early youth. Its progress is then apparently very slow.

DR. C. S. O'BRIEN, Iowa City. Dr. Knapp asks where the opacities begin. Apparently they are not typically subcapsular but appear first in the areas of the cortex that underlie the anterior and posterior subcapsular areas, i.e., in the anterior portion of the anterior cortex and in the posterior portion of

the posterior cortex. I may say that I have followed the entire development of opacities in several lenses. I have seen these normal lenses become completely opaque. That is, to me, of course, an argument against any congenital factor, since I believe that congenital lens opacities do not progress, except perhaps the coronary cataract of Vogt. As regards the iris, I have looked for indications of pathologic changes, but the only changes that might indicate disturbances such as those seen in the pigment epithelium under the microscope are deposits on the posterior surface of the cornea and in some instances on the anterior surface of the lens. So far as I have been able to determine, effective treatment of the diabetes slows down the process but eventually progression of the cataract has been noted in every lens. In answer to Dr Gifford, I must disagree with the idea that the snowflake opacities appear directly under the capsule in the subcapsular area, and then owing to the formation of new lens fibers, are forced toward the nuclear area; these opacities are seen first not in the subcapsular area but deeper in the cortex, and I see them progress over a period of weeks and in some instances over a period of months. New lens fibers are not formed with such rapidity. As to Dr Blaauw's feeling that perhaps these lens opacities are congenital I have only to reply that I have watched them develop with a rapidity that is not possible in congenital cataract. I have seen some of them develop in five or six weeks, and congenital opacities do not form in such a manner.

## SUBDURAL HEMORRHAGES

TIMOTHY LEARY, M.D.

BOSTON

Mystery has always shrouded the supposedly rare condition to which Virchow gave the name of pachymeningitis hemorrhagica interna chronica. Neither the title nor Virchow's study of the subject tended to abate the mystery. It is my purpose in this paper (1) to endeavor to dispel this mystery, (2) to demonstrate that the condition is not rare, (3) to call attention to its operative curability in many cases and (4) to indicate its possible medicolegal relations.

The Massachusetts medical examiner law gives the medical examiner exclusive opportunity to investigate deaths by violence. This exclusive opportunity entails a stewardship with a responsibility for the proper use of the material that comes into his hands. One of the implied obligations of the medical examiner is to aid or if possible to stimulate medical progress in dealing with the results of traumatism. The appalling death rate from automobile and other traumatic hazards approximates wartime mortality records and has made a deep impression on American vital statistics. Head injuries are responsible in my experience for about 45 per cent of the deaths from automobile injuries. In a study during the past four years of several hundred fatal traumatic cases, arising from many hazards in which intracranial lesions were found significant subdural hemorrhages were present in 10 per cent and were accountable either directly for the fatal outcome or for disability and mental deterioration.

An investigation from the standpoint of the possible salvage of cases of cranial traumatism suggested that subdural hemorrhages offered a promising field as a beginning. When it was brought to their attention that this lesion was relatively common, and that sur-

gical intervention offered the only practical solution, cooperation of the departments of neurology and of neurosurgery of the Boston City Hospital developed a diagnostic and operative technic that has led to the saving of lives, and, what is more important, of mentalities.

A primary part of this work has been a restudy of the subdural space.<sup>1</sup>

### THE SUBDURAL SPACE

It has been taught that the subdural space is a serous space, analogous to the great serous spaces of the body proper. The difference in the reactions of the two apposed surfaces lining the space is totally unlike the reactions that are manifest in the other serous spaces. The pia-arachnoid has the function of carrying the large vessels over the surface of the brain in such a manner that no large arteries actually penetrate beneath the surface of the brain. It distributes and absorbs the cerebrospinal fluid and serves as a water bed for the brain. It is impervious to most substances, alcohol and a few drugs alone being capable of penetrating the membrane. In this way it serves as a barrier between the blood and the central nervous system. It is the only membrane in the body that can hold back an infection whose products bathe its surface, as in pachymeningitis. Unlike the serous membranes, infections beneath the surface of which tend to spread rapidly into the serous cavities, leptomeningitis tends to be limited within the arachnoid, extension to the subdural space occurring rarely. Another evidence of the imperviousness of this membrane is its ability to hold large quantities of fluid in the presence of edema, while the subdural space contains a minimal amount. The membrane resists the invasion of meningiomas and plays no part in the removal of blood from the subdural space. Though capillaries have been seen in the membrane, it has no capillary bed.

To the contrary, the dura offers little resistance to the invasion of the subdural space by infections that have succeeded in getting into its tissues; it is invaded by meningiomas, it has a capillary bed and it assumes the burden of organizing and removing subdural hemorrhages.

By a simple technic we were able to demonstrate that though sheets of clean cut flattened cells (endothelium, or possibly mesothelium?) could be readily scraped from the surfaces of the serous spaces—pericardium, pleura and peritoneum—scrapings from the dura disclosed elongated fibroblastic cells with a small mixture of flattened cells of the mesothelial type. The arachnoid, on the other hand, is covered by an irregular often multilayered integument of flattened cells.

The manifest differences in the two membranes lining the subdural space have suggested to me the concept that the skull, like other bones, enters into articulation. In this case the articulation is not with bone but with a compound organ, the brain with its covering pia-arachnoid. The relations of the two structures, skull lining and brain covering, are largely those of contiguity, the only continuity arising from nervous and vascular connections and minor supports for the falx. From this point of view the dura is the lining of an articulation and has the character of a simple fibroblastic tissue, which Maximow has shown to be the standard lining

of the synovial spaces. This concept simplifies the approach to the study of subdural hemorrhages.

#### SUBDURAL HEMORRHAGES

Fifty cases of subdural hemorrhage in this series have been divided into the following five groups for convenience of study.

1 In eleven cases the hemorrhage was fresh, in the form of fluid blood or soft clots, which could not be preserved (fig 1).

Fig 1—Stage 1, characterized by fresh blood. Compression and molding of brain on left and flattening of brain on right are shown.

2 In six cases the blood was in the form of firmer clots, which tended to adhere to the dura (fig 2).

3 In fourteen cases the hematoma appeared in the form of chocolate clotted blood and yellow fluid adherent to the dura with beginning organization and a neomembrane from the dural side but no inner limiting membrane (fig 3).

4 In fourteen cases the hematoma showed a completed double membrane.

with an internal layer enclosing the chocolate clot and brownish fluid (fig 4).

5 In five cases a fused neomembrane without hematoma and almost complete healing marked the terminal stages of the lesion (fig 5).

These divisions serve as a rough measure of the age of the hemorrhage, death having followed too rapidly in the first two groups to permit of any organization, the third group showing early organization, i. e., on one side only of the clot, the fourth group showing more advanced organization and a neomembrane enveloping the clot, the fifth group showing an almost healed process.

#### STATISTICAL DATA

Stage 1. In the eleven cases in this series the ages varied from 14 to 63 years. Six were men, five were women. Six were not addicted to alcohol, five were alcoholic. Death occurred in periods of from one-half to eighteen hours after symptoms appeared or following falls, with one exception. In three cases blows on the head had preceded the death. In three cases falls on stairs, in one a fall from a couch, in one a fall on the ice, were apparently the means of provoking hemorrhage. In one case the rupture of the pedicle of a meningioma, in a second case the rupture of the dura in advance of a parotid myxochondrosarcoma led to the hemorrhage. In one alcoholic individual there was no history of injury. Ecchymoses of the scalp were found in three cases. In no case was there a fracture of the skull. In seven cases the hemorrhage was on the right side in four cases it was on the left.

Stage 2.—The ages ranged from 36 to 56 years. There were three women and three men. There was a history of trauma occurring from seventeen hours to three days before death. Five out of the six patients

were addicted to alcohol. Falls on the street in two cases, in one case on the stairs and in one case on the floor preceded the death. In two alcoholic patients there was no record of injury. In three cases there were ecchymoses of the scalp. The skull was fractured in one case following a fall down stairs. The hemorrhages were on the left side in four patients and on the right side in two.

Stage 3. The ages ranged from 28 to 67 years. There were seven women and seven men. Seven patients were alcoholic and seven were not. In four cases there was no history of trauma. In the others there was a history of injury occurring from a few days to fifteen days before death. In five cases falls on the floor, in two cases falls on the ice, in one case a fall on the stairs, in one a fall from a cot and in one striking of the head by a falling wrench had been the cause of the injury. In seven cases a visible contusion of the scalp was disclosed at postmortem examination. No skull fractures were found in this group. The hemorrhages were on the right side in nine cases and on the left side in five.

Stage 4. The ages ranged from 42 to 78 years. All fourteen patients were men. Seven were alcoholic and seven were not. The completed membrane in this stage indicates a process that has taken at least a month, usually months and possibly years to develop. The shortest dependable history was that of a man, aged 78, a carpenter, who fell a distance of 3 feet from a ladder thirty-nine days before his death. In a second case in a man who twenty-one days before death fell from a table 3 feet high, landing on his buttocks, without striking his head, the character of the membrane indicated that the lesion was of much earlier development. A third patient fell down stairs three months before death. A fourth had a fall on the floor three months before death. A fifth was struck by an automobile four months before death. A sixth was struck by a falling coal chute six months before death. A seventh fell striking his head six months before death. An eighth

Fig 2—Stage 2, characterized by a nonadherent clot.

had a fractured skull one year before death. In the other cases there was no history of an old injury. Two individuals in this series had been struck by automobiles, one fell backward down stairs, four fell on the street or on the floor a few days before death. In two of these, minor recent fractures of the orbital plates without brain injury were found at postmortem examination. In one case a fall down stairs resulted in a temporal fracture with epidural hemorrhage seventeen days before death. In one patient, a man found uncon-

scious on the street, a fracture of the base of the skull with contusion and laceration of the basilar surfaces of the frontal lobes was present. The hemorrhages were on the left side in eight cases, on the right side in three and bilateral in three. Massive recurrent hemorrhages had occurred in five cases, in three of which the inner neomembrane was ruptured and much of the clot lay free in contact with the arachnoid.

**Stage 5** This group consisted of five men ranging in age from 47 to 84 years. Three were alcoholic. The histories are unsatisfactory, two of the patients suffering from post-traumatic psychosis and a third being epileptic. In one case a fracture of the skull due to an automobile accident had occurred one year and four days before death. In a second case an old fracture had been followed by epilepsy. In two cases recent fractures of the skull, due to a fall in one case and to an automobile accident in the other, had preceded the death. In both cases there was contusion of the scalp. The membrane was bilateral in four of the five cases and unilateral on the right side in one.

**Combined Data**—In the fifty cases studied the ages ranged from 14 to 84 years. Thirty-four were men,

to alcohol. In a larger clinical series, alcoholic addiction was reported in 40 per cent. The higher mortality rate in alcoholic individuals is probably responsible for the difference in this respect.

#### PATHOGENESIS OF SUBDURAL HEMORRHAGE

This series of cases permits a visualization of all stages in the evolution of the process from fresh hemorrhages responsible for rapid death through the various degrees in the formation of the clot and the neomem-

Fig. 4—Stage 4 showing double neomembrane with clot between layers. Molding of the brain is shown.

brane, the hemolysis and liquefaction of the hematoma to the late picture of a fused thin velvety pigmented membrane.

**Etiology**—The Source of the Hemorrhage. It is evident that hemorrhage into the subdural space can arise from the rupture of vessels anywhere in the structures abutting on or lining the cavity. In the new-born the dura is considered to be the site of most of the lesions through birth injury usually to the tentorium. In skull fractures, laceration and contusion of the brain

Fig. 3—Stage 3 showing outer neomembrane with chocolate clot adherent to the dura.

sixteen were women. The women were limited to the first three stages. They appeared to suffer more serious hemorrhages or succumbed more readily than men. Twenty-seven were addicted to alcohol, twenty-three were not. Hemorrhages were unilateral in forty-three cases and bilateral in seven. Of the forty-three unilateral hemorrhages, twenty-two were on the right side and twenty-one on the left. In five cases recent fractures of the skull were found in cases with old neomembranes. In two of the older cases with membranes, recent minor fractures of the orbital plates were found. In four cases, evidences of old cerebral traumatism were found.

#### COMMENT

In many of the cases the minor character of the traumatism that leads to a subdural hemorrhage is striking. Relatively trivial blows or falls on the head, which are suffered daily without harmful results by many individuals and which have been experienced previously by victims of subdural hemorrhage without harmful effects may be responsible for a hemorrhage at a critical moment. Indeed, falls without injury to the head have been apparently efficient in producing the lesion.

The relation of alcoholism to the condition is close. In this series, 54 per cent of the victims were addicted

Fig. 5—Stage 5 showing fused double neomembrane. Window showing dura beneath.

is the usual source. In the cases included in this series, unassociated with fracture, the dura was responsible for two cases. In one case rupture of the pedicle of a meningioma led to rapid death from arterial and venous bleeding. In the second case a myxochondrosarcoma of parotid origin, which had penetrated the skull, led to stretching and rupture of the dura with associated hemorrhage. In the cases unassociated with fracture of the skull or evident brain damage it is impossible to determine the source of the hemorrhage if time enough

## SUBDURAL HEMORRHAGES—LLARY

JOUR. A. N. A.  
SEPT. 22 1934

has elapsed to obscure or heal the bleeding vessel. In the cases accompanied by rapid death, in which the blood is found still fluid at autopsy, search for the source is more fruitful. In eight cases I have been able to find the bleeder, which in five cases was a torn bridging vein and in three cases a vein at the surface of the arachnoid. The slowness with which blood frequently collects in the hemorrhages unassociated with marked trauma-

Fig 7—Junction of two layers of neomembrane with clot enclosed. Note giant capillaries.

tism is an added indication that the hemorrhage is usually venous and perhaps intermittent as the intracranial pressure increases and is modified when the brain accommodates itself to the increasing pressure. Though the subdural space is a cavity, hours at least are often necessary before urgent symptoms appear.

Death in the rapidly fatal cases is due to the sudden rise in intracranial pressure. In cases of more slowly developing hemorrhages, headache, semicomat, transient hemiplegia, hyperactive reflexes and spastic quadriplegia may be present. In the cases of the more chronic type, mental deterioration and psychoses mark the course of the disease. It is amazing how much compression the brain will stand if the compressing force is slowly applied. Some of the brains in this series present a degree of deformity that would seem to be inconsistent with even vegetative functioning.

**Alcoholism.** The relation of alcohol addiction to the production of subdural hemorrhages is significant. It is possible that the associated edema of the arachnoid may serve mechanically to favor rupture of bridging veins. More reasonable is the belief that alcoholism leads to more frequent traumas that are responsible for the result.

**Hemorrhagic Diathesis.** No evidence of a tendency to hemorrhage could be ascertained in the cases reported in this series. A fatal subarachnoid and subdural hemorrhage, largely subdural, occurred in a case of Streptococcus hemolyticus septicemia following abortion in one of my earlier series.

**Pathology.**—The subdural space is a closed space. When blood or exudate escapes into it the only means of removal are absorption, organization, or operative removal through an opening in the skull. There is no

evidence that the impervious surface of the arachnoid or the relatively avascular dura can bring about any measurable degree of absorption as such. Unlike the repair processes seen in the serous cavities in which all surfaces in contact with foreign material, either blood or exudate, take part in the organization, the effort to remove the material in the subdural space is the function of the dura. The impermeable, highly vascularized arachnoid, lacking a capillary bed, plays no part in the procedure.

As the dura is a dense fibrous membrane which is poorly vascularized, though it is a support for large blood vessels, the beginnings of organization are delayed. Evidence of the adhesion of the clot to the dura and the beginning of granulation is usually manifest only during the second week or later. There is first formed a thin layer of young tissue along the whole of the dura in contact with the blood, and small flying buttresses of vessels and fibroblasts are thrown out into that layer of the clot nearest the dura. As the proximal layer of granulation tissue develops there is slowly formed at the edges of the clot a layer, which spreads over the internal surface of the clot (fig 7). Ultimately, in a period which requires weeks in most cases, the internal layer envelops the clot, separating it from the arachnoid.

The outer membrane may be relatively thick and it is vascular. There is a moderate degree of vascularity of the portions of the inner layer that are nearest the dura. The midportion of the internal enveloping membrane is always paper thin and made up of a few

Fig 11—Giant capillary with rupture at upper end and hemorrhage.

layers of fibroblastic cells without vessels (fig 8). In the meantime, changes in the blood pigment result in a brownish discoloration leading to formation of a chocolate clot.

Hemolysis is relatively late, but after a period, usually of weeks to months, liquefaction of the midportions of the clot may give rise to a central cavity containing brownish fluid. Histiocytes invade the clot and are

found in numbers in the young tissue, loaded with blood pigment. They also invade the arachnoid barrier and give up their pigment in the arachnoid spaces to the cerebrospinal fluid, producing xanthochromia. This color reaction may be very marked in some cases and may be almost absent in others. It has diagnostic significance when it is found.

When the repair process has progressed to a certain degree, the handicap under which it is working comes

Fig 12—Stage 4. Recurrent hemorrhage. Fall of 3 feet with headache thirty nine days. Hemiplegia seventeen days. Two planes of compression of the brain are shown.

into evidence. Both the density and the relative avascularity of the dura play a part. The principal difficulty arises from the inefficiency of the venous drainage. The possibilities of venous outflow through the venous channels in the dense tissue are limited at best, and new channels are apparently not produced. A passive hyperemia of the granulating layer is an early phenomenon.

The capillary vessels become overdistended with blood, and so called giant capillaries result (fig 9). These vessels with thin walls of the capillary type may become so distended that they may reach a diameter equal to eighteen times that of a normal capillary. The back pressure may even dilate vessels on the arterial side, which, few in number, are readily identified by their relatively thicker walls. Active repair under these conditions tends to come to a standstill. Remarkable is the failure in most cases to form a layer of dense scar tissue such as arises in granulating processes elsewhere when healing is long delayed. Though a layer of what might be called scar tissue may arise directly along the dura, the tissue in general tends to be relatively edematous and not too rich in collagen.

The breaking up of the complex albuminous molecules of the blood detritus into simpler molecules tends to increase osmotic pressure with the absorption of fluid. Even with this dilution the fluid within cystic hematomas may be under such pressure that it spurts forth for a distance when the membrane is incised during operation in some cases.

Because of the imperfection of the healing, a subdural hematoma once established may persist for years. Dr Myrtelle Canavan presented before the Massachusetts Medical Society an underdeveloped brain with its membranes, compressed by a bilateral subdural hematoma which from the history had been present in a boy for twelve years. There was no more evidence of complete healing in this case than is apparent in cases in which the lesion is only months old.

Another factor of importance in delaying healing is the occurrence of secondary hemorrhages (fig 10). As would be expected, the thin-walled giant capillaries, poorly supported in the flimsy granulation tissue, are prone to rupture (fig 11). Secondary hemorrhages occur usually within the completed membrane of the fourth stage. In three of the cases in the series under consideration the new hemorrhage had burst through the thin inner layer of the neomembrane and much of the clot was found lying free on the inner surface of the membrane. Repeated hemorrhages of lesser degree serve to prolong the healing of the lesion. Massive secondary hemorrhages are not infrequently responsible for the fatal issue (fig 12).

**Inflammatory Cellular Infiltration** Inflammatory reactions are commonly associated with the process of repair. Lymphoid cell infiltration in minor degree of the neomembrane is frequently encountered. Larger focal accumulations of lymphoid cells may be seen, notably in older processes, and focal infection with a polymorphonuclear infiltration is a possibility. It was undoubtedly the study of the later stages of the condition, in which the inflammatory cellular reaction was marked, that led Virchow to refer to it as pachymeningitis. Pathologists who have approached the problem from the study of advanced lesions have seen the subdural hematoma as a complicated picture difficult to explain. Oozing hemorrhagic processes from the inflamed arachnoid in syphilitic meningo-encephalitis may lead to minor degrees of subdural neomembrane formation and have tended to confuse the issue. In the standard form of subdural hemorrhage the basic process is that of a poorly supported attempt to organ-

Fig 13—The crux of the situation. Branches of a single vein from a peeling of the neomembrane. The vessels are outlined by pigmented histiocytes. The area shown would present many vessels in normal granulation tissue.

ize, hemolyze and remove a blood clot. The inflammatory cellular infiltration is incidental or accidental.

**Location of the Clot and the Membrane** Remarkable is the tendency of subdural hemorrhages to be unilateral. In forty-two cases in this series in which there was no fracture of the skull, the process was

unilateral in thirty-eight. It is difficult to believe that the tentorium and the falx can serve as water tight or blood tight partitions. The accumulation of the blood on one side, however, tends to crowd the brain toward the other side and the molding together by pressure of brain, falx and tentorium serves as an efficient barrier to the escape of blood onto the side opposite the source of the hemorrhage, or beneath the tentorium. This mechanism is so constant in its effects that one is led to wonder in the cases showing bilateral hematoma whether two separate hemorrhages did not occur.

In the eight cases associated with fracture the lesions were bilateral in four old cases, two with psychosis, one with epilepsy. The presumption in the others was that there had been some bilateral accumulation of blood, but the collection was much larger on one side than on the other with resulting early removal of blood on the side less affected.

The mass of the clot in fresh cases and the hematoma with membrane in late cases occupies a position over the cerebral convexity, almost without exception. In our series the distribution was usually over the frontoparietal area, with inclusion of the temporal and occipital areas in part when the lesion was extensive. In general the location tended to be more toward the frontal than toward the occipital regions when the area covered was less extensive. Gravity may be a factor in leading to this localization but it is difficult to account completely for it on this basis in individuals who were found lying on the back, in the early deaths with fluid hemorrhages, and remained so. It is not uncommon in fresh fractures to find the occipital lobes covered with a considerable layer of blood, but hematomas are rare in this region.

In one exceptional case the thickest layer of clot lay between the falx and the mesial surface of the brain, largely over the posterior half of the cerebrum. Subtentorial lesions are almost entirely limited to fracture cases with traumatism to the cerebellum and are of little practical importance. The real problem is the hematoma over the convexity with its compression of the brain. The usual location of the clot over the anterior convexity in most cases has favored its discovery by temporal exploratory burrhole operation.

#### FREQUENCY

In my opinion this series does not measure accurately the frequency of subdural hemorrhages. The diagnosis outside the hospital was successfully made in but one of the cases of spontaneous hemorrhage, the erroneous diagnoses being largely divided between alcoholism and cerebral hemorrhage, though in one case a diagnosis of thrombosis of the middle cerebral artery was arrived at after careful neurologic study. The large additional group of cases diagnosed and successfully treated at the Boston City Hospital supports the belief that the condition is not rare.

Operative removal of the subdural membrane is easily possible, since the anchorage of the neomembrane to the dura is poor. The density of the dura apparently prevents the almost continuous formation of new vessels as seen in granulation tissue elsewhere. The paucity of new vessels is well illustrated in figure 13. The blown up dilated so-called giant capillary is really a sinusoidal vessel, as seen in figure 14. Recurrence of the hemorrhage after removal of the membrane is unusual if the brain expands.

#### MILDCOLEGAL RELATIONS

Several of the cases in this series arose in individuals at work and appeared to be related to occupation. It is not my purpose here, however, to deal with the industrial or accident insurance aspects of the subject. The criminal relations are of greater importance. Two cases illustrating possibilities which may arise out of subdural hemorrhages are submitted.

**CASE 1—C. F.**, a man, aged 57, was drinking with an old friend in his own bedroom. An argument arose, during which the friend pushed the victim, who fell and struck his head against an iron bed. He immediately complained of headache and in a short time became unconscious. On admission to a hospital he was in coma with stertorous respiration. The pupils were pin point and did not react. The reflexes were hyperactive. Bilateral positive Babinski reflexes were obtained. He remained in coma and died ten hours after admission. Postmortem examination disclosed hemorrhagic infiltration of the deep layers of the scalp in the left temporoparietal region with a small hematoma. The skull was thicker than average, measuring 1 cm in thickness in the frontal region, 0.4 cm in the temporal region and 0.9 cm in the occiput. The left subdural space contained a layer of clotted blood measuring up to 1.2 cm in thickness over the left cerebral hemisphere. The clot thinned out over the posterior convexity and the dura at the base was painted with a thin layer of blood. The left hemisphere was compressed and molded by the clot, the right was flattened against the skull. There was no fracture of the skull or contusion of the brain. Apart from moderate tortuosity of the vessels at the base of the brain the autopsy was otherwise not remarkable. There were no external marks of violence on the body other than the left temporoparietal hematoma.

Evidence was produced in court that the assailant had been an intimate friend of the decedent for many years and that they had never seriously quarreled. The court was informed that the postmortem observations were consistent with the claimed accidental misadventure. The court ruled that the death was due to accidental homicide.

**CASE 2—V. C.**, a Syrian girl, aged 14 years, was found dead, lying on a pile of rubble alongside an alley that separated a gasoline station from a shallow cellar from which a house had been removed. Both hips were swollen and lacerated. A confused laceration 4 cm in length, extending up through the subcutaneous tissues to the mandible, ran to the left from a point 1 cm to the left of the midline and 2.5 cm below the point of the chin. There was a red ecchymosis over the right cheek bone. The hands were abraded over the knuckles bilaterally as though the body had been dragged to the position where found with the hands scraping the ground. The body was fully dressed except for drawers. The stocking on the right leg was torn with a series of holes on its outer aspect, and the skin underneath was reddened with superficial abrasion. The vaginal introitus showed swollen and hemorrhagic carunculae myrtiformes almost encircling it. There was hemorrhagic infiltration of the left labium over a region 1.4 cm by 0.3 cm. There was a laceration of the perineal skin 1 cm in length, gaping 0.3 cm.

Postmortem examination revealed hemorrhage in the left frontal area and a region of deep hemorrhagic infiltration over the left parieto-occipital region near the midline. The subdural space on the left side contained a mass of fresh clot measuring up to 1 cm in thickness. The left subdural space was smeared with a thin layer of blood. The brain was molded by the clot on the left and flattened on the right. Subarachnoid hemorrhage was present over the anterior frontal convolution, and a bridging vein about 1.5 cm from the mesial junction was torn. There was no fracture of the skull and no contusion of the brain.

On the following day the assailant, a young sailor, was arrested. He confessed that he had taken the girl into the shallow cellar, on her agreement to permit intercourse. It was evident that perhaps because of dyspareunia, the experience was unpleasant. The girl screamed and tried to fight him off.

The boy admitted that he then had punched her, driving her head against the brick wall behind her. She again screamed and he ran away. Examination of the boy by alienists brought out evidence of mental inferiority and moral abnormality. He pleaded guilty to murder in the second degree and was given life imprisonment.

From a medicolegal standpoint, subdural hemorrhages present many problems. The minor character of the traumatism that may invoke a fatal hemorrhage and the possible implication of alcoholism in the etiology furnish weapons to the defenders in cases under trial, which tend to influence jurv action. The occurrence of psychoses in chronic cases in this series leads one to wonder whether the fused neomembranes so frequently found in postmortem examinations in psychopathic hospitals do not indicate in some cases that a subdural hemorrhage had preceded and caused the psychosis. The failure to include examination of the head as a routine part of a complete postmortem examination has resulted in overlooking many cases of subdural hemorrhage.

#### CONCLUSIONS

Subdural hemorrhages are not rare but have been largely overlooked.

The source of the hemorrhage in cases unaccompanied by fracture of the skull is usually a ruptured bridging vein or an arachnoidal vein.

Alcoholism is a favoring factor.

The hemorrhage tends to be unilateral.

The inability of the relatively avascular dura to organize the subdural clot efficiently and resulting repeated secondary hemorrhages are responsible for the chronicity of many cases.

Inflammatory reactions in connection with repairing lesions are incidental or accidental.

The only practical method of cure of the condition is by operative intervention.

818 Harrison Avenue

#### ABSTRACT OF DISCUSSION

DR MILTON HELPER, New York. I should like to ask Dr Leary whether he considers the etiology to have been traumatic in those cases of bilateral pachymeningitis hemorrhagica interna which are seen very late, without any history and without any obvious signs of recent trauma.

DR TIMOTHY LEARY, Boston. In the series reported, forty two, or 84 per cent, were unilateral. Two were bilateral. These were all due to minor venous ruptures, in which the bleeding vessel could be demonstrated. The remaining six were late results of fracture of the skull. The presumption is that with venous hemorrhage the blood as it accumulates forces the hemisphere on the affected side against the falx and the tentorium and thus produces blood-tight joints with these membranes. Rarely this mechanism fails to work and a bilateral lesion results. It is also possible to have bilateral ruptures of vessels. I have been able to obtain a history of traumatism, not necessarily though usually to the head in practically all cases. The traumatism is sometimes minimal, a fall of two or three feet.

**Hobbies**—Holidays and hobbies the two alliterative allies for health and happiness of which no profession than ours stands in greater need are often neglected by the hard-working medical fraternity. The vast majority of practitioners cannot, as business men do take the week end off and thus secure perhaps a quarter of the year for recreation or like clerics concentrate their activities on the first day in the week. Further medical practitioners whatever sound directions on the subject of holidays they may dispense to patients do not, it is to be feared always set a good example in this respect—Rolleston Sir Humphry. General Medical Aspects of Holidays *Practitioner* 133 129 (Aug) 1935

## NECROTIZING ULCERS COMPLICATING ERYSIPELAS

PAUL F STOOKEY, M.D., CARL R FERRIS, M.D.

HUBERT M PARKER, M.D.

LOUIS A SCARPELLINO, M.D.

AND

KIM E ENGLISH

KANSAS CITY, MO

During the past two years we have observed five instances of necrotizing ulcers complicating severe erysipelas. These ulcers were confined to the edematous, loose areolar tissue about the eyes. The distinguishing characteristics of the ulcers were their rapid development, phagedenic properties, punched out appearance, edematous base and profuse, creamy, yellow discharge. Two of the five cases resulted fatally. Three cases were observed in the Isolation Hospital, one in consultation with Dr A E Eubank and one in consultation with Drs H B Davis and Donald R Black. The three cases observed in the Isolation Hospital were available for a bacteriologic study, which is the basis of this paper.

#### REPORT OF CASES

**CASE 1**—A white woman, aged 28, entered the hospital, Feb 22, 1933, with typical severe erysipelas of the face. The loose areolar tissue about the eyes was markedly edematous. Three days later a necrotizing process developed in the edematous tissue. It extended rapidly and developed a punched out appearance with very little inflammatory reaction in the periphery. The process was limited to the edematous, loose areolar tissue of both eye regions. A profuse, creamy, yellow pus exuded from the necrotic areas. Direct examination of a smear of the pus showed staphylococci. The same staphylococci were isolated in pure culture.

**CASE 2**—A white man, aged 40, entered the hospital, Feb 25, 1934, with severe erysipelas of the face. A necrotizing process developed in the markedly edematous areolar tissue of the left upper eyelid two days later. The necrotic ulcer was characterized by rapid development, phagedenic appearance and sharply defined edges with little inflammatory change in the periphery. Staphylococci were observed in the direct examination of a smear of the pus and were isolated in pure culture.

**CASE 3**—A patient of Dr A B Jones, a white man, aged 74, entered the hospital, April 1, 1934, with typical severe erysipelas of the face. A necrotic ulcer with punched out appearance was noted in the edematous, loose areolar tissue of the left upper eyelid at the time of admission. Staphylococci were seen in the direct examination of a smear of the purulent discharge from the ulcer and were isolated in pure culture. Subsequently the patient developed suppurative cervical adenitis in which the same causative organism was demonstrated. The patient made an uneventful recovery.

The occurrence of ulcerative lesions in the course of erysipelas was to us an extremely unusual clinical phenomenon. The rapidly necrotizing character of these ulcers and the persistent finding of staphylococci both by culture and by smear suggested a superimposed infection from a skin contaminant developing on a suitable nidus. The offending organism was suspected to have dermonecrotic properties from the rapidly destructive character of the lesions. The organism was recognized to be a staphylococcus by its morphologic and cultural characteristics.

Billroth Koch Ogston Rosenbach and Pasteur<sup>1</sup> were early workers with the pyogenic cocci during the

From the Contagious Service of the Kansas City General Hospital. We are indebted to Dr Ralph Emerson Duncan for the cooperation of the laboratory and the use of its facilities and to Dr Frank J Hall for the interpretation of the pathologic and histologic specimens.  
<sup>1</sup> Pasteur Louis. *Bull Acad de med Paris* 9 435 1880

seventies of the last century. The etiologic role of the streptococcus in erysipelas was established by Fehleisen.<sup>2</sup>

The fact that staphylococci grow luxuriantly on all ordinary mediums made for the rapid advance of the knowledge concerning the organism. Staphylococci

Fig. 1 (case 1)—Pustular lesions around the eyes which developed eight days subsequent to the onset of the erysipelas and two days subsequent to admission to the hospital.

were originally classified by the color of the colonies into aureus, citreus and albus types. Of late the classification by their action on various sugars has received much attention. The staphylococci are distributed widely in man and the higher animals. The various strains vary enormously in virulence. The yellow pigment producing strains are usually more virulent than the white strains, but there are many comparatively avirulent yellow strains and many virulent white ones. Most cultures of staphylococci are hemolytic and many nonpathogenic strains are markedly hemolytic. This fact excludes the possibility of associating the presence of hemolysis with pathogenicity.<sup>3</sup> Certain strains of staphylococci produce free toxin, or exotoxin. In our strains of staphylococci, now under study, the exotoxin, with lethal and dermonecrotic properties, was the outstanding feature observed. That leukocidin was present in the filtrate of certain strains of staphylococci was established by Van de Velde<sup>4</sup> in 1894. He also noted the production of this toxin, which was thermolabile and independent of pigment production or hemolytic properties. It is evident that a filtrate of bacteria may contain split products that are toxic but are not true exotoxins. The filtrates from staphylococci have not received the

study recorded the classic toxin elaborated by the Klebs-Loeffler organism. However, the behavior of the staphylococcus filtrate, its toxoid forming properties, and its specific antigenic properties, leave little room for questioning the fact that this substance is a free toxin perhaps of complex nature, containing a hemolysin, a cell poison, leukocidin, and other dermonecrotic toxins. Antiserum has the property of binding this toxic filtrate.<sup>5</sup> According to our experience the staphylococcus shows no tendency to pass the filter and the filtrates are sterile to culture.

From the case of necrotizing ulcers occurring as a complication of erysipelas, a staphylococcus was obtained in pure culture. The clinical appearance of the pus presented all the characteristic features of a staphylococcal infection. This culture was transferred to a dextrose broth medium. A second culture was transferred to a broth medium free from sugar. These are called filtrates A and B. Filtrate C made from case 3 was obtained from sugar-free medium. The literature contains many observations on the inhibiting property of the sugars on toxin formation.<sup>6</sup> Filtrates were obtained following Burnet's technique.<sup>5</sup> The hemolytic properties of these filtrates were determined by the following method:

To a rack of tubes containing 1 cc of physiologic solution of sodium chloride, toxin was added in vary-

Fig. 2 (case 1)—Appearance five days subsequent to figure 1 showing phagedenic character of the ulcerations.

ing dilutions. To this mixture was added a 0.5 per cent suspension of washed rabbit red blood cells. The tubes were placed in a water bath at 36 C for one-half hour. The results are shown in table 1. Red cells from the rabbit were used because they are considered more resistant to this toxin and the results are said

resulting toxemia. This occurred in the rabbit inoculated with filtrate C.

Control rabbits receiving cutaneous injections of filtrates from a streptococcus cultured from the blebs occurring in a case of erysipelas showed no necrosis. The culture medium passed through the filter produced

Fig 4 (case 3)—Destructive ulceration of the upper eyelid developing in the course of the erysipelas.

The lesions resulting from the injection of 0.2 cc of filtrates A and B were excised for histologic study. Dr. Frank Hall of the pathologic department of the

Fig 5—Areas 2, 4, and 6 received respectively 0.1, 0.2, and 0.3 cc of filtrate A obtained from case 2 grown in broth containing dextrose. Areas 1, 3, and 5 received respectively 0.1, 0.2, and 0.3 cc of filtrate B obtained also from case 2 but grown in dextrose free broth. Note the inhibiting properties of dextrose on the dermonecrotic properties of the toxin filtrate. Photographed seventy-two hours subsequent to injection.

Kansas City General Hospital furnished the following histopathologic report:

The section marked "infiltrate A" shows subdermal inflammatory reaction of a necrotic character. The entire area involved is necrotic, the cells have undergone marked degen-

erative necrosis. No blood vessels can be made out in this section, so the blood vascular reaction cannot be described. The derma very close to the necrotic area is perfectly normal and shows no peripheral infiltration. The most marked change aside from the necrosis is found in the musculature. The

Fig. 6—Section of rabbit's skin receiving filtrate B intracutaneously. Biopsy done on fourth day following injection. Note the area of necrosis on right without inflammatory reaction.

Fig. 7—Areas 1, 2, 3, 4, 5 and 6 received respectively 0.1, 0.2, 0.2, 0.3, 0.4 and 0.5 cc of filtrate C obtained from case 3, grown in dextrose free broth and administered intracutaneously. Death occurred on the tenth day. Note spreading of area 6. This is the most potent staphylococcus filtrate we have obtained. Photographed seventy-two hours after injection.

muscle fibers have undergone complete necrosis and take a deep stain. The fibers have become granular and in some places it looks as though crystalline material has been deposited in the centers of the fibers.

The section marked "infiltrate B" shows changes identical with those found in the "infiltrate A."

Following the injection of this sterile staphylococcus filtrate into the vein of the ear of the rabbit, death occurs in from a few hours to several days, depending on the amount of toxin injected and its potency. Rabbit 2, weighing 2.5 Kg, injected in the ear with 0.4 cc per kilogram of body weight filtrate A, died five days later. Rabbit 3, receiving 0.45 cc per kilogram of body weight of filtrate B, lived for eleven days before death occurred. Rabbit 1, receiving 0.9 cc per kilogram of body weight of filtrate A, died thirteen hours later. Rabbit 6, receiving 2.3 cc per kilogram of body weight of filtrate A, died fourteen hours later. Control rabbits injected with the filtrates from the broth culture medium showed no unfavorable reaction. Filtrates from a streptococcus cultured from the blebs occurring in a case of erysipelas were nontoxic in intravenous doses of 3 cc per kilogram of body weight.

Fig. 8—In the back of a shaved rabbit area 1 received 0.1 cc of staphylococcus filtrate obtained from a furuncle, no ulceration was observed. Area 2 received 0.2 cc of the same filtrate, no ulceration developed. Area 3 received 0.1 cc of streptococcus filtrate obtained from the blebs occurring in a case of erysipelas. Area 4 received 0.2 cc of the same streptococcus filtrate. Areas 5 and 6 were injected with the broth culture medium. The filtrates and culture medium showed no dermonecrotic properties. Photograph made seventy-two hours subsequent to injection.

The postmortem changes subsequent to death from the intravenous administration of staphylococcus filtrate were not striking. On the instance in which death occurred within twenty-four hours subsequent to injection, macroscopic examination showed nothing of note aside from marked pigmentation of the liver. In the instances in which death occurred from three to five days subsequent to intravenous injection, marked emaciation and diarrhea occurred. The fur became rough and food was refused. Dr. Hall furnished the following report of the microscopic examination of the organs of rabbit 6, dying fourteen hours subsequent to injection.

The heart muscle shows alternate dark staining and light staining muscle fibers. The light staining fibers show con-

siderable longitudinal fibrillations. The darker muscle fibers show peculiar obliteration of the striations. There is no perivascular infiltration about the blood vessels.

The spleen shows marked acute splenitis. Examination with the high power lens shows the splenic sinuses filled with large histiocytes, many containing granules of blood pigment. The splenic follicles are almost obliterated.

The kidneys show marked passive congestion. There is some swelling of the proximal convoluted tubular epithelium. No casts are found. Many of the glomeruli are quite large and injected with blood corpuscles. There is a considerable amount of congestion of the blood vessels between the collecting tubules.

The liver shows narrowing of the cell columns with considerable blood in the liver sinuses between the cell columns. There is no increase of cells in the liver. The central veins are distended. No change is noted in the portal canal. No round cell infiltration is seen.

#### COMMENT

Necrotizing ulcers developing as a complication in the course of erysipelas are due to a staphylococcus having dermonecrotic properties. The necrotizing fac-

Fig 9—Section of heart muscle of rabbit 6 receiving 2.3 cc of filtrate A per kilogram intravenously showing degenerative changes in heart muscles. Death occurred fourteen hours after injection.

tor is contained in a bacteria-free filtrate and is presumably an exotoxin. Administered intravenously, it is lethal to rabbits. The lethal dose varies over a wide range. It depends on the ability of the staphylococcus in question to manufacture toxin. In our experiments the most potent toxin produced death in five days subsequent to the intravenous administration of 0.4 cc per kilogram of body weight. Larger doses of toxin produced death in as short a period of time as eleven hours. The postmortem examination did not show striking changes if death occurred after a few hours. If the dose of toxin was small emaciation was marked whether the toxin was administered intravenously or cutaneously. Diarrhea was usually present. In rabbits dying several days later, microscopic evidence of toxic damage to the heart, liver and spleen was noted. Hemolysis *in vitro* of human blood on blood agar plates is not necessarily a measure of the ability of the staphylococcus to produce free toxin. The intracutaneous injection of 0.1 cc of this toxin will produce necrosis of a rabbit's skin in thirty-six hours. A cul-

ture medium containing dextrose inhibits toxin formation. Filtrates of *Streptococcus erysipelas* showed no dermonecrotic properties in the rabbit's skin and were inert when injected intravenously in doses of 3 cc per kilogram of body weight. Filtrates from a non-hemolytic staphylococcus obtained from a furuncle showed no necrotizing properties although the organism produced yellow pigment. It is interesting to note that the staphylococcus is one of the group of organisms which Wright<sup>8</sup> named serophytes because of their ability to grow freely in unaltered human serum.

#### CONCLUSIONS

1 Necrotizing ulcers are occasionally encountered as a complication of erysipelas.

2 The presence of such ulcers enhances the gravity of the prognosis.

3 The ulcers occur in the loose, areolar tissue about the eyes.

4 Necrotizing ulcers complicating erysipelas result from a secondary superimposed infection produced by a staphylococcus possessing the ability to manufacture an exotoxin which is dermonecrotic and hemolytic.

## RESPONSE OF PERITONEAL TISSUE TO DUSTS INTRODUCED AS FOREIGN BODIES

JOHN W. MILLER, M.D.

R. R. SAYERS, M.D.

WASHINGTON, D. C.

AND

WILLIAM P. YANT, B.S.

PITTSBURGH

The response of the body tissues to various kinds of dust has been a subject of much interest in recent years. Mavrogordato, Gardner, Gye and others have conducted experiments on the action of inhaled dusts. Kettle<sup>1</sup> has studied the response to dusts injected into the subcutaneous tissues and intratracheally, and Policard<sup>2</sup> has used the cornea and conjunctiva in his recent studies. In 1924 experiments were begun at the Pittsburgh Station of the United States Bureau of Mines to determine the action and fate of various dusts when injected into the peritoneal cavity of guinea-pigs.<sup>3</sup> The conclusions reached at that time were that live animal tissue in all parts of the body tends to react in essentially the same manner to foreign bodies and that fibrous tissue is formed in the peritoneal cavity by quartz and is not formed by limestone and coal. This paper is a continuation of these earlier studies.

<sup>8</sup> Wright A. E. Brit. M. J. 2: 629, 1915.

From the Office of Industrial Hygiene and Sanitation, United States Public Health Service, and the Pittsburgh Experimental Station of the United States Bureau of Mines.

Read before the Section on Preventive and Industrial Medicine and Public Health at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 14, 1934.

Part of the expenses incurred in this study were defrayed by the Metropolitan Life Insurance Company. Mr. W. A. Selvig and Mr. A. H. Emery of the United States Bureau of Mines made the chemical and petrographic examinations of the dusts used in these experiments. <sup>1</sup> Kettle E. H. <sup>3</sup> Sayers R. R. Health Hazards in the Mining Industry. U. S. Bureau of Mines Report of Investigation 2660, December 1924.

Owing to the length of time required to obtain a reaction by inhalation methods and the desirability of determining the harmfulness of a dust in a relatively short time, other methods of introducing the dusts to be studied were considered. Injections into the peritoneal cavity seemed to give the most promise, because of the relatively circumscribed area of the cavity, the ease in controlling the amount of the dose, and the preservation of the sterility of the material introduced—a factor to be considered in inhalation and intratracheal methods. The mortality from peritonitis or peritoneal damage following intraperitoneal injection was found to be negligible. Identical reactions were found in each animal injected with the same dust under the same conditions and examined at the same time interval after injection. Therefore the fact that the reaction to the dust involves both epithelial and connective tissue is of no disadvantage.

The reaction is essentially the same microscopically as that produced in the lungs, and the gross appearance

In a later series, a Roller type air separator<sup>4</sup> was used. This method of elutriation did not separate all the dusts in the series into fractions of the same size, yet it did produce, with one exception, samples less than 5 microns in maximum measurement. The exception, soapstone, measured 8 microns as a maximum particle size. The median size of the dusts used in this series varied from 0.75 to 1.7 microns, with soapstone measuring 3.5 microns. Such small variations in particle size appeared to be of no importance in comparing the physiologic responses produced by the dusts. It can be readily seen that the air separated particles more closely approximate those inhaled under industrial conditions. While smaller particles were preferable because of their greater assimilation by the cells, the particles that had been passed through a 325 mesh sieve gave the same gross reactions and, in the case of all dusts mentioned in this study, can be used in place of the smaller particles obtained with greater difficulty. Water separation was not attempted, because of the possibility of removing soluble portions of the dusts and thus altering their chemical composition.

#### TECHNIC OF INTRAPERITONEAL INJECTIONS

A weighed portion of the dust and a few glass beads to facilitate suspension were placed in a small wide mouthed bottle and sterilized in a hot air oven for one hour at 150 C. After cooling, sufficient sterile physiologic solution of sodium chloride to make a 10 per cent suspension was added, the bottle was closed with a sterile rubber stopper, and the whole was thoroughly shaken. Owing to the fact that a suspension of fine dust causes a locking of the plunger of a hypodermic syringe, air-bulb syringes of 3 cc. capacity were used. Needles of 21 or 24 gage were found most suitable for the injections. The needles and syringes were sterilized in boiling water before use.

The hair on the right side of the animals' abdominal wall was clipped and tincture of iodine was applied. For injection, 2 cc. of the 10 per cent suspension, equivalent to 0.2 Gm. of dust, was introduced intraperitoneally into each pig. As the needle was withdrawn, a very small quantity was injected into the subcutaneous tissue to serve as a marker of the site of injection. This marker made it possible to observe whether any trauma was produced by the introduction of the needle into the peritoneal cavity and its effect on the reaction instituted by the dust.

Certain groups of animals were injected with air separated material and other groups with 325 mesh material. The former were killed and examined 7, 14, 30, 56, 90, 180 and 360 days after injection and the latter at intervals of 7, 14, 30, 56 and 112 days after injection.

#### DISTRIBUTION OF THE DUST IN THE PERITONEAL CAVITY

With the exception of bituminous coal the greater part of each of the dusts in this series was found in the peritoneum of the anterior abdominal wall, the most dependent portion of the peritoneal cavity. The site of the next largest collection was the omentum. Small nodules and dispersed collections of particles were also found in the inguinal canals, on the mesentery, liver, intestine, testes or uterus and diaphragm. A very little

Fig. 1—Above caliche, below, limestone. Appearance of nodules on anterior abdominal wall seven, thirty and ninety days after injection.

of the dust nodules is sufficiently differentiated to afford a means of classifying the physiologic response to the dusts. In the series studied here, there were three types of reaction, namely, an absorption or dissolution of the dust, a proliferative reaction, and an inert reaction. In the inert reaction the dust neither caused an increase in the size of the nodules nor disappeared from the tissues, instead there was more or less change in its distribution in the peritoneum. These reactions will be discussed more fully under the different groups of dusts.

#### PREPARATION OF THE DUSTS FOR INJECTION

It was desirable for the particle size of each dust in the series to conform as closely as possible to that of the other dusts used, and also to be as small as possible without a change in the physical or chemical composition. Particles passed through 100, 200 and 325 mesh standard sieves were used in one series of tests with several dusts.

The 325 mesh size was found to be the most suitable, because of the greater facility with which a reaction is produced. The particles obtained by passing a dust through a 325 mesh sieve were less than 43 microns in size.

<sup>4</sup> Roller, P. S. Construction of Accurate Air Separator. *Indust. & Engin. Chem.* 4: 341-343 (July 15) 1932.  
S. Bloomfield, J. J. The Size Frequency of Industrial Dusts. *Pub. Health Rep.* 48: 961-968 (Aug. 11) 1933.

was occasionally found on the posterior abdominal wall. In the case of bituminous coal, the greater portion was found in the omentum and mesentery, while a relatively small part was present on the anterior abdominal wall. As a basis of comparison in describing the reactions caused by the dusts, the nodules formed on the anterior abdominal wall were used, since they were more accessible and were more constant and uniform in appearance. The response in the omentum or at any other point in the peritoneal cavity was, however, the same as that found on the anterior abdominal wall. Nodules were only infrequently found in the peritoneum at the site of the entrance of the needle—so rarely, in fact, that it was safe to assume that the trauma produced by the introduction of the needle was negligible.

#### THE PERITONEAL RESPONSE TO THE VARIOUS DUSTS

**Calcite**—After being injected into the peritoneal cavity, calcite formed nodules that were irregular and more or less discrete but often clumped. A small amount of congestion and edema was noted about the edges of the nodules in the early stages, but this had subsided before the end of thirty days after injection. This congestion and edema were evidently due to the initial foreign body injury instituted by the dust. The nodules became progressively smaller as the interval between injection and examination increased, and this decrease in size was accompanied by the production of brown pigment particles, which were first noted at the edges of the nodules and later covered their entire surfaces and were found dispersed into the adjacent peritoneum. The original dust eventually disappeared, leaving a small area of fine brown pigment particles at the site of the nodule. These, in turn, soon disappeared without the formation of scar tissue. This type of reaction, namely, the disappearance of the dust from the peritoneal cavity, has been designated, for the sake of description, as one of absorption.

**Limestone**—Limestone caused a reaction of absorption similar to that of calcite. The rate in which the dust disappeared from the tissues was much slower than in the case of the purer Iceland spar. In 180 days after injection, practically all of the original dust had disappeared. After 360 days no original dust was present and the amount of brown pigment was materially less than was noted in 180 days. The initial foreign body irritation, the production of the brown pigment and the disappearance of the dust from the peritoneum without the formation of scar tissue was identical with the process produced by calcite.

**Precipitated Calcium Carbonate**—Precipitated calcium carbonate produced a tissue response very much like that of calcite and limestone. The formation of the nodules was identical in character, and the original dust disappeared in about the same length of time as in the case of calcite, yet more brown pigment was produced, which lingered in the tissues for a longer time than did that formed by calcite. This increased production of pigment might be attributed to the fact that the dust was in a state allowing easier assimilation by the cells. The pigment particles were much smaller and much more numerous than those produced by either calcite or limestone. No evidence of scar tissue formation was noted in any of the animals examined. The reaction was clearly one of absorption.

**Gypsum**—Gypsum eventually produced a response similar to that of calcite. In the early stages the dust

appeared to lie inert in the peritoneum without any appreciable change. By the end of thirty days a slight decrease in the amount of dust was noted, and by ninety days this decrease was marked. The nodules became progressively darker as the interval between injection and examination increased, but the production of brown pigment, noted in the other three dusts, was scanty or entirely absent. Fine dust particles, more or less isolated, were noted in the peritoneum. These may have been the remains of nodules or else particles disseminated by phagocytes. The diminution in size of the nodules was not as rapid as in the case of calcite, limestone and precipitated calcium carbonate, yet this response was sufficiently marked to designate the reaction as one of absorption.

**Portland Cement**—Portland cement produced a reaction slightly different from that caused by calcite, limestone, precipitated calcium carbonate and gypsum, yet the ultimate outcome appeared to be one of absorption. The initial foreign body irritation was quite severe—

Fig. 2—Above quartz, below chert. Appearance of nodules on anterior abdominal wall seven, thirty and ninety days after injection.

so marked in fact, that sixteen of thirty-six guinea-pigs injected with this dust died during the tests. This was probably due to the chemical properties of the cement. The animals that survived showed extensive peritoneal congestion and edema in the early stages. After this reaction had subsided, the dust decreased in quantity, with the formation of a light brown pigment similar to that produced by calcite, limestone and precipitated calcium carbonate. In 180 days after injection practically all of the dust and a large portion of the pigment had disappeared.

**Quartz**—After an initial stage of foreign body irritation, manifested by edema and congestion about the collections of dust in the peritoneum, quartz produced nodules that progressively increased in size. These nodules, when occurring in clumps, fused together, forming a large single mass. Numerous capillaries were present on the surfaces and throughout the nodules. The appearance was that of cellular proliferation and was apparently due to the chemical irritation supplied by the solution of the silica in the tissues. The maximum size of the nodules was observed ninety days after injection. After this period they became more firm, contracted and fibrous in appearance. At the end of

360 days this induration was quite marked. This type of reaction, for convenience of description, will be referred to as one of proliferation.

**Chert**—Chert caused a reaction similar to that of quartz, though the nodules produced by this dust were larger in size than those formed by the quartz. The color of the nodules, which was the same as that of the dust introduced, remained constant throughout the duration of the tests. The reaction produced by chert was decidedly one of proliferation.

**Soapstone**—Soapstone produced the same type of reaction in the first two weeks after injection that was noted in all of the other dusts, namely, an initial foreign body irritation. This early fixation reaction was not severe and subsided quite rapidly. As the time between injection and autopsy increased, the nodules, at first raised and rounded, became flattened and spreading. The edges became irregular, and numerous fine dust particles were noted in the peritoneum adjacent to the edges of the nodules. Collections of these particles were found at various other points in the peritoneum. The amount of dust in the peritoneal cavity found 360

days after injection was approximately the same as that found in seven days. The response of the peritoneal tissue to this dust is therefore one of inertness.

**Jewelers' Rouge**—Jewelers' rouge, or ferric oxide, behaved in the peritoneum in a manner similar to that of soapstone and silicon carbide. The nodules became flattened, and many fine dust particles were extensively disseminated throughout the peritoneum as the time interval between injection and examination lengthened. The amount of dust observed 360 days after injection was approximately the same as that found in seven days. The response of the peritoneal tissue to this dust is therefore one of inertness.

**Anthracite Coal**—Anthracite coal produced a more rapid response than did soapstone, silicon carbide or jewelers' rouge. Minute dust particles were noted in the peritoneum adjacent to the nodules as early as seven days after injection. By ninety days this distribution was quite extensive. In 180 and 360 days the quantity of this dispersed dust was less, though the amount of dust found in the peritoneal cavity was approximately the same as that found in seven days. It was concluded that anthracite coal was inert in reaction.

**Bituminous Coal**—Like soapstone, silicon carbide, jewelers' rouge and anthracite coal, bituminous coal appeared to be inert and insoluble in the peritoneum. The nodules behaved in a manner similar to those of the dusts that have been named, and the dispersion of the dust particles throughout the peritoneum was particularly widespread. With this dust very few nodules were found on the anterior abdominal wall, but the majority were consistently found in the omentum. Many small nodules and diffuse areas of dust particles were also found in every portion of the peritoneal cavity. The amount of dust present 360 days after injection was approximately the same as that found in seven days, therefore the reaction was one of inertness.

**Precipitator Ash**—Precipitator ash, or "fly ash," produced a reaction similar to that of the other inert dusts mentioned in this series. The nodules behaved similarly in their progress to those formed by soapstone. Relatively coarse, black particles were noted on the surfaces of the dark gray nodules. These were evidently carbon particles, as the dust was of mixed composition. The dissemination of the original gray dust composing the bulk of the sample, while not as extensive as that of the coals, was well marked and was like that noted with soapstone and silicon carbide. As there appeared to be no cellular proliferation or disappearance of this dust from the peritoneal cavity, it seems logical to class this dust as inert in type.

#### CHEMICAL AND PETROGRAPHIC ANALYSES OF THE DUSTS

**Calcite**—Pure Iceland spar was used, chemical analysis of which showed calcium carbonate 99.8 per cent and silica 0.1 per cent. Petrographic examination showed a high purity calcite. The median size of the particles was 1.4 microns.

**Limestone**—A high grade Pennsylvania limestone was used. The chemical analysis showed calcium oxide 54.4 per cent, magnesium oxide 0.4 per cent, iron and aluminum oxides 0.4 per cent and silica 1.5 per cent. Petrographic examination showed granular, irregularly rounded calcite. The median size of the particles was 1.45 microns.

Fig. 3—Above anthracite coal, below jewelers' rouge. Appearance of nodules on interior abdominal wall seven, thirty and ninety days after injection.

days after injection was approximately the same as that noted in seven days. The injected dust was not absorbed and did not initiate a cellular proliferation. The only change noted was that of the distribution of the dust in the peritoneum. The particles became more widespread in their dispersion as the interval between injection and examination increased, and this dissemination was shown microscopically to have been effected by macrophages. Since no dissolution of the dust or cellular proliferation occurred, this type of reaction will be referred to as one of inertness.

**Silicon Carbide**—Carborundum, or silicon carbide, produced essentially the same type of reaction as soapstone. The initial stage of foreign body irritation was not as severe, and the distribution of the fine dust particles in the later stages of the tests were more extensive. Though the nodules became more flattened and spreading, the amount of dust found in the peritoneal cavity 360 days after injection was approximately the same as that noted in seven days. The material is apparently a nonirritating, insoluble foreign body and is readily transported throughout the peri-

**Precipitated Calcium Carbonate**—This substance is a chemical by-product. The chemical analysis showed calcium carbonate 87.9 per cent, magnesium carbonate 10 per cent, magnesium oxide 0.1 per cent, iron and aluminum oxides 0.6 per cent, and silica 0.4 per cent. The median size of the particles was 1.28 microns.

**Gypsum**—The uncalcined, natural mineral was used. The chemical analysis showed silica 1.3 per cent. Petrographic examination showed approximately 30 per cent as calcite in the form of rounded granules and irregular rhomboidal crystals and approximately 70 per cent as fragmented particles of gypsum. The median size of the particles was 1.3 microns.

**Portland Cement**—The chemical analysis of the Portland cement showed calcium oxide 74.4 per cent, magnesium oxide 2.8 per cent, silica 21.1 per cent. Petrographic examination showed normal Portland cement. The particles were sharp and angular. The median size of the particles was 1.05 microns.

**Quartz**—Two specimens of quartz were used. One was ground rock crystal of high purity. Chemical analysis showed 99.4 per cent of silica. Petrographic examination showed clear, crystalline normal quartz. The median size of the particles was 1.7 microns. The other specimen was finely ground Pennsylvania quartz, commonly called flint. The chemical analysis showed 99.1 per cent silica. Petrographic examination showed normal quartz of high purity. The median size of particles was 1.6 microns.

**Chert**—A highly siliceous chert, the waste product from the concentration of lead and zinc ores, was used. Chemical analysis showed 76.1 per cent silica. Petrographic examination showed quartz and chert, stained with limonite, predominating. About 25 per cent of the silica was normal angular quartz fragments. The median size of the particles was 1.22 microns.

**Soapstone**—The chemical analysis of the soapstone showed total silica 49.9 per cent, calcium oxide 1.7 per cent and magnesium oxide 26.2 per cent. Petrographic examination showed about 30 per cent as tremolite, about 65 per cent as talc and about 5 per cent as dolomite. The median size of the particles was 3.5 microns.

**Silicon Carbide**—Pure manufactured silicon carbide was used. Petrographic examination showed no impurities. The median size of the particles was 1.15 microns.

**Jewelers' Rouge**—The jewelers' rouge was pure ferric oxide in a finely divided state. The chemical analysis showed ferric oxide 98.3 per cent and silica 1.5 per cent. Petrographic examination showed a high purity hematite as fine uniform particles. The median size of the particles was 0.95 micron.

**Anthracite Coal**—Two specimens of Pennsylvania anthracite were used. The chemical analyses were approximately the same. Petrographic examinations showed about 95 per cent as coal and about 5 per cent as inorganic material. Of the latter, about 60 per cent appeared as quartz and about 40 per cent as calcite, siderite and rutile. The median sizes of the particles were 0.75 and 1.11 microns, respectively.

**Bituminous Coal**—Two samples of Pennsylvania bituminous coal were used. Chemical analyses showed one to have 8.5 per cent ash of which 0.8 per cent was silica, and the other to have 8 per cent ash of which 3.5 per cent was silica. The median sizes of the particles were 1.15 and 1.19 microns.

**Precipitator Ash**—The precipitator ash was collected from stacks by electrical precipitation. Chemical analysis showed 44.7 per cent silica. Petrographic examination showed predominantly perfectly spherical fused glass, rounded semifused masses made up of crystallites, some quartz fragments, calcite and coal. The median size of the particles was 1.43 microns.

#### CONCLUSIONS

The tissue of the peritoneal cavity responds actively to a dust introduced as a foreign body, and this response is of such a character that it may be used as a basis for the classification of industrial dusts with reference to their pneumoconiosis producing properties. This response falls into three groups, namely, one of absorption, one of proliferation and one of inertness. While, in these experiments, animals were kept on test for as long as 360 days, the response is sufficiently well marked in ninety days to determine the type of reaction, and often conclusions can be reached in thirty days, particularly if the reaction is one of absorption or proliferation. The reaction elicited by each dust was constant and uniform in all the animals injected with that dust. The experiments of long duration reported here confirm the results noted in a previous paper.<sup>6</sup> It appears that this response of the peritoneal tissue to various dusts can be used as a test to determine the possible harmfulness of an industrial dust.

#### ABSTRACT OF DISCUSSION

DR A. J. LANZA, New York. At a time when the subject of the possible effects of industrial dust is of paramount importance, it is refreshing to see a clear-cut piece of laboratory work. The authors inject the dust intra-abdominally, and the results in the case of siliceous dust are in conformity with what would be expected from a knowledge of the clinical picture of the action of these dusts in the pulmonary tissues of human beings. This marks, I hope the beginning of a series of such experiments, which will give industrialists and physicians information as to whether or not any dust present in working operations has characteristics of harmful nature. The advantage of this method is that it does not take the length of time that is spent in the artificial inhalation dusting of experimental animals, which not infrequently has to be carried on for from three to even five years. In this case the results are obtained within weeks or a few months.

DR WILLIAM D. McNALLY, Chicago. Was a histologic study of the specimens made in the calcium experiment? There is an area extending farther than the calcium, and I can't quite agree that there is no change, because the area appears abnormal when compared with the surrounding peritoneal tissue. An area of normal tissue is present and, further, a white area that looks as if there was a calcium soap being formed. Similar pictures are seen in disease of the pancreas, in which there are erosions of the peritoneum and depositions of a calcium soap. If that should happen in the small alveoli of the lung with calcium definite damage would occur. I should like to have that explained.

DR E. R. HAYHURST, Columbus, Ohio. The study is a decided advance in available methods of estimating diagnosis and prognosis in industrial dust work. I do not believe, however, that such studies will answer all questions in relation to the harmfulness of so-called nonpoisonous dusts. I have seen dusts that were 99 per cent silica, which, because of peculiar physical properties, would not remain suspended in the air so that they could be inhaled, at least in amounts that would be likely to get beyond the normal nasal dust trap. Therefore, the testing of a "proliferative" dust by this method would not necessarily mean that it might damage the lungs in industrial

6 Miller J. W. and Sayers R. R. The Physiological Response of the Peritoneal Tissue to Dusts. Pub. Health Rep. 49: 80-89 (Jan. 19)

exposures May I ask what kind of tissue forms over these dust particles when they are inert or absorbed? I can understand the reaction in the proliferative type, but it seemed to me that the first two would also cause some sort of reaction, which might be seen microscopically if not in the specimens shown in the display in the Scientific Exhibit

DR JOHN W MILLER, Washington, D C Microscopic sections of the pigmented remains of calcite nodules showed a larger number of fat cells than did the other portions of the peritoncum I did not find any calcium in these sections by staining methods Both Dr Gardner and I think that the pigment is possibly of hematogenous origin, some of these particles responded to an iron reaction and some did not In answer to Dr Hayhurst's question, a thin capsule was noted over the dust nodules of the inert-reaction group, but the dispersion of particles was a characteristic feature in the peritoncum These particles were engulfed by macrophages, which fact was particularly well illustrated in the case of carbon particles This is a preliminary paper, reporting only a portion of the study

### CLINICAL CIRCULATORY EFFECTS OF DINITROPHENOL

A B STOCKTON, M D

AND

W C CUTTING, M D

SAN FRANCISCO

During the clinical use of sodium dinitrophenol (1-2-4) in obese patients, the occasional appearance of subjective symptoms such as tachycardia, dyspnea and profuse diaphoresis<sup>1</sup> suggested the necessity of investigating the effects of the drug on the circulation

Thirteen patients with apparently normal cardiovascular systems were selected for this study Six of the group were placed at bed rest in the hospital, and control observations of blood pressure, pulse rate, vital capacity and venous pressure made regularly at 8 a m, 2 p m and 7 p m The control period was continued until at least three consecutive results were in close agreement A mean of three or more control results

Chart 1—Mean per cent changes in systolic and diastolic blood pressure and in vital capacity of thirteen patients following the daily oral administration of 300 mg of sodium dinitrophenol Solid line systolic pressure line of dots and dashes diastolic pressure broken line vital capacity

was taken as the base The control period was never less than three days and was sometimes as long as five days A quantity of 300 mg of sodium dinitrophenol was then administered orally in three divided doses

From the Departments of Pharmacology and of Medicine Stanford University School of Medicine

Supported in part by a grant from the Rockefeller Fluid Research Fund of the Stanford University School of Medicine

Read before the Society for Experimental Biology and Medicine Pacific Coast Branch, at the American Association for the Advancement of Science Berkeley Calif June 21 1934

1 Tainter M L, Stockton A B and Cutting W C Use of Dinitrophenol in Obesity and Related Conditions J A M A 101 1472 (Nov 4) 1933

each day, and the circulation and vital capacity were observed for from four to twelve days

The ambulatory patients were treated in a similar manner, except that the same functions were observed once daily at 4 p m Before the observations were made, the patient was required to rest in a prone position without pillows for one hour

Chart 2—Mean per cent changes in pulse rate and venous pressure of the same group of patients Solid line venous pressure broken line, pulse rate

Blood pressure readings were taken by the same observer, using a standardized mercury manometer The pulse rate was counted for three full minutes, with intervals of five minutes between the counts, and an average used Vital capacity was measured by means of a Collins spirometer, the average of three different trials being used Venous pressure changes were measured by a direct method suggested by Dr William Dock and described by Rytand<sup>2</sup> In this method an intravenous needle inserted into the median cubital vein is connected by means of a Kauffman-Luer syringe to a water manometer The readings were made only after a period of three or more minutes without change in the level of the manometer The results obtained are presented as curves in the accompanying charts showing changes in the different physiologic functions observed

#### RESULTS

Vital capacity and systolic and diastolic blood pressure were not significantly affected by the sodium dinitrophenol Most of the individual variations fell between 10 per cent above and 10 per cent below the control level (chart 1)

Definite increases in venous pressure and in pulse rate occurred in ten of the thirteen cases studied These increases showed much fluctuation The individual variation in pulse rate was between -11.6 per cent and +30.1 per cent, and in venous pressure between -16.9 per cent and +49.5 per cent (chart 2)

The concurrent increases in pulse rate and venous pressure explained the maintenance of normal blood pressure in spite of the marked peripheral vasodilatation resulting from the dinitrophenol Patients stated that the sensation of warmth and the sweating occurred

2 Rytand D A The Effect of Digitalis on the Venous Pressure of Normal Individuals J Clin Investigation 12 847 (Sept) 1933

in waves likely to be excited by exertion, by a warm, humid atmosphere, or by drugs causing peripheral vasodilatation, such as acetylsalicylic acid or alcohol. In patients under observation during these periods of vasodilatation, maximum increases in venous pressure and in pulse rate were demonstrated. Chart 3 shows the results obtained in patient M, which were characteristic for other patients. Despite the variability in all observations, it was quite evident that, while no significant changes occurred in blood pressure and in vital capacity, there were definite increases in pulse rate and in venous pressure.

Observations by one of us (S) of blood pressure and pulse rate changes in a separate and larger group of seventy-five ambulatory patients indicated that there was an ultimate reduction in both systolic and diastolic pressures. These reductions were probably due to loss of body weight, since they persisted after the dinitrophenol had been discontinued. However, these observations are being extended in a larger number of

Chart 3—Consecutive actual changes in blood pressure, pulse rate, vital capacity and venous pressure in patient M receiving daily therapeutic doses of sodium dinitrophenol. First segment blood pressure changes represent millimeters of mercury; pulse, pulse rate per minute. Second segment P P X P R = pulse pressure times pulse rate.

ambulatory patients in order to determine the significance of the changes. A considerable time must elapse before results on several hundred patients are obtained and prepared for publication.

#### CONCLUSIONS

The oral administration to resting patients of sodium dinitrophenol in therapeutic doses, during short periods of time, caused no significant changes in vital capacity and in blood pressure.

There were significant increases in pulse rate and in venous pressure. These increases persisted during the medication and were maximum during the periods of peripheral vasodilatation caused by the drug.

**Intracranial Aneurysm**—In 1923, Symonds reported five cases of intracranial aneurysm in which the diagnosis was made during life. In two of his cases the diagnosis was confirmed by necropsy, in another case the necropsy was incomplete, and in the remaining two the patients were still living. This report served as the turning point from the time-honored tradition that an exact diagnosis of intracranial aneurysm was impossible during life. During the past few years several other papers have appeared containing the reports of cases in which a definite clinical diagnosis was established—Garvey, P. H. Aneurysms of the Circle of Willis, *Arch. Ophth.* 11 1032 (June) 1934.

## THE FATE OF THE "GOOD CHRONIC" CASE OF TUBERCULOSIS

### A YARDSTICK FOR THE RESULTS OF THORACOPLASTY

LAWRASON BROWN, M.D.

SARANAC LAKE, N. Y.

AND

HOMER L. SAMPSON, D.Sc.

TRUDEAU, N. Y.

Prof. Edward Archibald of McGill University, in describing the patients on whom he has performed the operation of thoracoplasty, has made use of the term a "good chronic" case of pulmonary tuberculosis, suggested to him, he states, by Brunner in his analysis of the operations of thoracoplasty performed in Sauerbruch's clinic. All patients coming to this severe operation have evidently well advanced cases of pulmonary tuberculosis, almost invariably with cavitation. The results obtained from thoracoplasty in this "good chronic" group are far better than those obtained in other groups, and in order to evaluate these results it becomes necessary to ascertain the results in a similar group in which no operation has been performed. Obviously the term "good chronic" implies the converse "bad chronic," and further study has brought out that an intermediate group, a group passing or slipping from the "good" to the "bad" chronic state, was of considerable importance in connection with the surgical treatment of pulmonary tuberculosis.

It is highly necessary to define what these terms imply. The criteria for a "good chronic" case are as follows: A cavity at least 2 cm. and usually larger in diameter must be present. The general condition must be favorable. The temperature and pulse must be normal during the period of observation of several months. The appetite and strength must be good and the patient must sleep well and be able to take some exercise. Expectoration may be present but must not be excessive. The number of tubercle bacilli in the sputum is not taken into consideration. Apart from the fact that the roentgenogram is used to detect or confirm the presence of cavity, the criteria are wholly clinical. Patients not conforming to these criteria would have to be classified as "bad chronics," but it soon became evident that the latter group was a broad one embracing many patients slipping from the better to the worse group. For this reason we think it best to recognize a "slipping" or intermediate group. We do this for the reason that in our opinion, patients in the "bad chronic" group do not as a rule respond any too favorably to surgical treatment. The patients most suitable for surgical intervention, if it is accepted that the "good chronics" do well in many instances without such treatment, are those slipping back from the "good chronic" group toward the "bad chronics."

In order to determine what happens to "good chronic" cases we studied 336 patients at the Trudeau Sanatorium (table 1) and forty-seven patients treated in the village of Saranac Lake. We noted the condition of the patients at the end of five and when possible at the end of ten years. Few of these patients received any form of surgical treatment and if so they did worse than those who received none. At the end of five years 80 per cent of the "good chronics" among the Trudeau patients were alive and only 38 per cent of the "bad chronics." Of the "good chronics" 54 per

cent were at work and of the "bad chronics" only 12 per cent. At the end of ten years the figures are, for the "good chronics," 64 per cent alive and 52 per cent at work, for the "bad chronics," 25 per cent and 11 per cent, respectively. The "good chronics" do

131 bad chronics	42	27	31

TABLE 5—Comparison of the Results of Medical and Surgical Treatment in "Good" and "Bad" Chronics

	Treatment	Time Elapsed in Years	Living	Dead	Work In.
200 good chronics	Medical	5	80	20	54
41 good chronics	Surgical (thoracoplasty)	0 10	8	15	
131 bad chronics	Medical	5	38	62	12
52 bad chronics	Surgical (thoracoplasty)	0 10	48	52	
266 effective artificial pneumothorax	Surgical	4 13	87 2	72 7	56 4
249 ineffective artificial pneumothorax	Surgical	4 13	20	70	5 6
142 thoracoplasty	Thoracoplasty	0 10	64	36	26

remarkably well and their conditions show little change in the number working at the end of ten when compared with those at the end of five years. During the first three years 14 per cent of the "good chronics" and 50 per cent of the "bad chronics" die, while at the end of five years the figures are respectively 19 per cent and 63 per cent and at the end of ten years 32 per cent and 75 per cent.

The figures for the small group of Saranac Lake cases show little differences, as can be noted from the accompanying tables.

From the figures at our command<sup>1</sup> we have been able to construct table 5, showing a comparison of the results of medical and surgical treatment in "good" and "bad chronics." The difference between the results of treatment in these two groups is very striking. Attention should be drawn to the very poor results obtained from ineffectual artificial pneumothorax.

It is of considerable interest that the figures recently collected by Hedblom show little difference from those collected some years ago by Alexander and published in his book on thoracic surgery. Roughly, one third of the cases are economic recoveries, one third of the patients are alive and one third of the patients are dead. We feel that in the future the thoracic surgeons in reporting their results should divide their cases into these three or other similar groups.

## Clinical Notes, Suggestions and New Instruments

### HYPERTHYROIDISM IN CHILDREN

CLARENCE K. JONES, M.D., CHICAGO

Hypertthyroidism in children is a rather rare disease. Occasionally a single case is reported, but most of the cases have been reported from the larger clinics. Dimsmore<sup>1</sup> of the Cleveland Clinic reported forty-eight cases in patients ranging up to 17 years of age, while Helmholz<sup>2</sup> reported thirty from the Mayo Clinic. Greene and Mora<sup>3</sup> from Richter's service reported twenty-six cases in their series, the ages ranging from 8 to 16 years inclusive. This represented 21 per cent of their 1,200 consecutive cases that came to operation. Twenty-two of these patients were girls and four were boys. One child, a girl, was 8 years old, two were 11, and one was 12, the rest of the patients were fairly evenly scattered over the next four year period. Cowden, reviewing the literature in 1923, found no case of hypertthyroidism in a boy under 10 years of age.

The symptoms in the cases cited were manifested for from two months to three years, the average being nine months. In Helmholz's series, tachycardia was noticed in all his thirty cases. Enlargement of the thyroid gland and nervousness were present in twenty-eight of the cases. Exophthalmos was a symptom in twenty-five. Loss of weight was noted in about half of the cases reviewed. Tremor, weakness, excessive appetite and free sweating were usually present.

From the foregoing it may be seen that the clinical picture of hypertthyroidism in children closely resembles that of the adult. The reason the loss of weight is not noticed in a greater number of cases is probably that the child is normally gaining several pounds annually at this age and that the toxicity from the hypertthyroidism is just about enough to offset the normal gain. In one case reported by Greene and Mora the gain was 7 pounds (3,175 Gm.) in spite of the toxic thyroid.

Existing factors were noted in several of the cases reviewed, such as tonsillitis, influenza, scarlet fever, colds and whooping cough.

The metabolic rate in Greene and Mora's series averaged 34.6 plus in 26 readings per child, the extremes being plus 86 and plus 13, the latter patient having been on iodine for seven

<sup>1</sup> We are indebted to Dr. J. N. Hayes and Dr. E. N. Packard for permission to use figures from their forthcoming book on artificial pneumothorax.

Read before the North Shore Branch of the Chicago Medical Society, March 6, 1934.

<sup>2</sup> Dimsmore, R. S. Hypertthyroidism in Children. Surg. Gynec. & Obst. 42: 172 (Feb.) 1926.

<sup>3</sup> Helmholz, H. F. Exophthalmic Goiter in Childhood. J. A. M. A. 87: 157 (July 7) 1926.

<sup>4</sup> Greene, E. I. and Mora, J. M. Thyroidectomy for Thyrotoxicosis in the Young. Surg. Gynec. & Obst. 53: 375 (Sept.) 1931.

weeks Helmholtz obtained readings varying from plus 11 to plus 55

In most of the cases reviewed, iodine was given prior to operation, by far the greater number of cases reacting favorably to the medication. Helmholtz stated that one of his cases showed no reduction in the metabolic rate after several weeks of compound solution of iodine.

The amount of thyroid tissue left at operation is usually greater than that left in the adult. It is ordinarily considered good surgery in the adult to leave no more thyroid gland than a piece equal to about the size of the distal phalanx of the thumb on the posterior capsule while it is the opinion of most surgeons today that three or four times that amount should be left in the child. Lahey<sup>4</sup> states that he prefers to do his operations on preadolescent thyroids in two stages with intervals of six weeks. However, it must be remembered that Lahey operates on most of his adult patients in two stages. Dinsmore felt it desirable to ligate the superior thyroid vessels some three months prior to the thyroidectomy.

At the Mayo Clinic there were two deaths following twenty-four operations, Greene and Mora had no fatalities in their series of twenty-six cases. Dinsmore fails to mention the mortality from the Cleveland Clinic. Recurrence was more common than in adult cases, but this may be accounted for by the necessity of leaving more thyroid tissue.

The following is a case of toxic thyroid.

#### REPORT OF CASE

L. C., a white boy, aged 10 years, brought to my office, June 2, 1928, complained of loss of weight, malaise, nervousness, inability to do school work, frequent bowel movements, and headaches.

The family history was negative except for the fact that I had operated on the father for hyperthyroidism, April 17, or about two weeks before examining this boy.

The patient had had measles, mumps, whooping cough, chickenpox, and tonsillitis. Tonsillectomy and adenoidectomy had been performed six years before. Six weeks before admission he had an acute cold with sore throat. The history further showed that shortly after the onset of this cold the present symptoms were first noticed.

The patient was frail, nervous, pale and emaciated, he weighed 68 pounds (30.8 Kg.), a loss of 10 pounds (4.5 Kg.) over a six weeks period. Tremor of the fingers was present and bilateral enlargement of the thyroid gland, especially of the right lobe. The pulse was 124, the hands were clammy and damp with perspiration. There was a slight bilateral exophthalmos, with some nystagmus. There was increased cardiac dullness, measuring 9 cm. to the left of the midsternal line. The urine showed a trace of albumin and a few leukocytes. Examination of the blood showed hemoglobin, 80 per cent, red blood cells, 4,660,000, white blood cells 11,200, differential count, normal, basal metabolic rate, plus 38.

The patient was put to bed with absolute rest, forced feeding with four feedings daily, and compound solution of iodine 3 minims (0.18 cc.) three times a day. During the next two months the pulse varied from 110 to 130. All other subjective and objective symptoms showed little or no change during this rest period of more than two months, so the patient was sent to St. Luke's Hospital for observation and treatment.

On admittance to the hospital the basal metabolic rate was plus 40, or an increase of two points over the test made more than two months before, in spite of the fact that he had been on iodine continuously and in bed during the entire period. The blood picture was practically unchanged and examination of the urine was negative.

After a few days rest and observation, an operation was decided on, and on August 17, or about two and one-half months after the initial visit, a thyroidectomy was done under gas anesthesia. Most of the right lobe was removed and about two thirds of the left. The wound was closed with a subcuticular stitch without drainage. The patient had a stormy time during the first four days after operation the pulse varying between 140 and 168 but by the fifth day it had dropped to

84. Iodine was continued daily, 5 minims (0.3 Gm.), during this period. The boy left the hospital ten days after the operation, at which time he was feeling fine, the pulse averaging about 80.

The pathologic report showed extensive hyperplasia of the thyroid alveoli with lymphocytic infiltration, only a few of the alveoli containing normal colloid material.

A metabolic test taken two months after operation gave a reading of minus 11. The weight was 84 pounds (38 Kg.) and the pulse 73. All other subjective and objective examinations were negative. Periodic check ups have been made over the last five years and to date there has been no return of symptoms, the boy developing into a normal young man of average weight and with a stable nervous system.

## Therapeutics

### THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.

CHICAGO

NOTE—In their elaboration, these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, Dr. Bernard Fantus. The views expressed by the various members are incorporated in the final draft prepared for publication. The series of articles will be continued from time to time in these columns.—Ed

#### THERAPY OF ANTHRAX

The diagnosis is given under Carbuncle.

#### PROPHYLAXIS IN ANIMALS

The carcass of an infected animal, which must not be skinned or opened, should be destroyed by burning, if possible, or otherwise by thoroughly covering with powdered unslaked lime and burying it, at least 6 feet deep, in an unfrequented fenced-off place. Ground contaminated with discharges should be burned over. If the animal dies in a stable, everything contaminated must be disinfected and, if possible, burned.

Animals should be protected by not being permitted to graze on land known or suspected to be infected and being kept during an outbreak from exposure to all insects that may act as carriers, until the animals are immunized.

Combined active and passive immunization should be accomplished by subcutaneous injection of antiserum and of vaccine. Immunity is acquired in ten or twelve days and lasts for at least a year.

#### PROPHYLAXIS IN MAN

Workers who handle suspected material, such as hides or wool, should be compelled to wear gloves and overalls while handling it. Three rooms should be provided for these workers: one in which they leave their work clothes, a second room, a lavatory in which they must cleanse the hands, face and other exposed parts thoroughly, paying special attention to keeping the finger nails clean, and a third room where they have left their street clothes. Wool sorters should be protected against possibly infected dust by wearing masks.

Slight abrasions and even small pimples should receive prompt treatment, and antiserum should be employed on mere suspicion of infection.

<sup>4</sup> Lahey, F. H. Primary Hyperthyroidism in Children. S. Clin. North America 9: 1327 (Dec.) 1929.

## TREATMENT

Anthrax antiserum should be administered at the earliest possible moment, locally as well as systemically.

Local injection is done after iodization of the skin surrounding the lesion, from 10 to 12 cc of the serum being injected through two or three punctures just outside the indurated border of the lesion and rather deeply (from 1 to 1½ inches) into the subcutaneous tissue at the base of the induration, in such a way as to circumscribe the lesion. Injections are repeated at intervals of twenty-four, twelve or, in severe cases, of six hours, until from four to six injections have been given or, rather, until the inflammation, which is increased after the first few injections, shows definite evidence of subsiding.

Systemic administration in nonsepticemic cases is carried out by means of intravenous injections of 50, 100 or 200 cc of antiserum every twelve to six hours (according to the severity of the case) until the disease is controlled, then intramuscular injections are given for several days longer.

In septicemic cases, i. e., those presenting a positive blood culture, 200 cc of antiserum is injected intravenously every three hours until the blood culture is negative.

Local treatment consists of absolute rest, elevation, and warm borie acid compresses until the eschar separates. No excision or cauterization is necessary. If an abscess forms, mere incision is enough. In properly managed cases the wound heals with a surprisingly small scar.

The fever regimen (q v) is followed.

## Council on Physical Therapy

THE FOLLOWING ARTICLE HAS BEEN ADOPTED BY THE COUNCIL ON PHYSICAL THERAPY AND THE COMMITTEE ON STANDARDIZATION AND DRUGS<sup>1</sup> OF THE SECTION ON OPHTHALMOLOGY OF THE AMERICAN MEDICAL ASSOCIATION.

H. A. CARTER, Secretary

### A PRACTICAL COMPARISON OF SOME INSTRUMENTS USED IN ORTHOPTIC TRAINING

GEORGE P. GUIBOR, M.D.  
CHICAGO

Because of the large number of instruments offered for the training of the fusion faculty in cases of squint, it would seem to be of value to discuss the indications for the use of some of these instruments and the results to be obtained.

These instruments may be classified according to their construction into

- 1 Instruments depending on the use of prisms to produce the superposition of images
- 2 Instruments depending on the reflection by mirrors to produce the superposition of images
- 3 Combinations of 1 and 2
- 4 Instruments depending on the projection of light forms on a screen to produce the superposition of images

From the Department of Ophthalmology, Northwestern University Medical School.

<sup>1</sup> The members of the Committee on Standardization of Instruments and Drugs are Dr. Sanford R. Gifford, Chicago, chairman; Dr. Francis Heed Adler, Philadelphia; Dr. Clifford Walker, Los Angeles; Dr. Jonas Friedenwald, Baltimore, Md.; and Dr. John MacNee, New York City.

The following list includes most of the instruments employed in the United States and England.

#### I Prism refracting instruments

##### (a) Stereoscope

- 1 Standard stereoscope (made in various models)
- 2 Variable prism stereoscope
- 3 Training stereoscope
- 4 Kinetic stereoscope
- 5 Telebinocular
- 6 Stereophorometer
- 7 Kratometer
- 8 Phoriascope
- 9 Stereocampimeter
- 10 Correct-eyescope (made especially for drawing)

##### (b) Normalizer

##### (c) Panocular

#### II Mirror reflecting instruments

- 1 Cheiroscope
- 2 Amblyoscope
- 3 Synoptiscope
- 4 Synoptophore
- 5 Stereo-orthopter
- 6 Orthoptoscope

#### III Combinations—stereocampimeter with mirror attachment

#### IV Projection of light in screen—myologic unit

In using any of these instruments, several facts must be remembered. First, no instrument, even if it is advertised as an automatic training device, will replace personal supervision and hard work in the training of fusion, the checking of progress and the determining of suppression. Second, all instruments have defects and limitations which are apparent only after orthoptic training has been attempted over a period of time with such equipment. Third, as the instrument becomes more technical and mechanical it requires more personal supervision and its practical uses can be less easily varied to suit individual cases. Fourth, the tendency to make use of elaborate and psychologically impressive instruments should be discouraged unless such equipment accomplishes definite results not obtainable with more simple apparatus.

As types of prism deflecting instruments, the ordinary Brewster or Holmes stereoscope or its modifications as listed are all valuable instruments. The simple hand stereoscope, as well as its more expensive modifications, appears to answer most of the requirements given for an efficient instrument. By varying the illumination and using large colored pictures before the suppressed eye, or by drawing pictures in the stereoscopes adapted for this purpose, it is usually possible to overcome suppression.

By the use of prisms, cases of squint of the accommodative type of as much as 35 degrees may be made to fuse with the stereoscope. By varying the distance between charts and reducing the amount of prism necessary to superimpose the images and later substituting prisms of opposite sign which call for more muscular effort, all the various steps in orthoptic training may be accomplished with the stereoscope. With the stereoscope, much depends on the type of card employed. With the split charts, which contain a few simple objects in marked stereoscopic relief and in which the distance between charts may be varied, such as those of Sattler and the author, it is surprising how often patients with squint of long standing will fuse at the first or second attempt.

In divergent squint, however, of an amount greater than 20 degrees, the use of the stereoscope is usually impossible until necessary surgical procedures have been performed to reduce the angle of squint

With the many cards at one's disposal, the routine can be made so variable and stimulating that young children will cooperate and enjoy the exercises for as long as an hour. Parents can learn the use of the stereoscope readily and can cooperate in home training.

Objective methods for checking subjective or psychologic reactions have been formulated.<sup>1</sup> The cost of this instrument is exceedingly small.

The objections to the small hand stereoscope are that there is some prismatic distortion at times, that it is limited to squint of 35 degrees, or less, depending on the type of squint, and that no kinetic or rotatory stimulus can be produced with this rigid instrument.

As a type of mirror reflecting instrument, the one most commonly employed is the amblyoscope of Worth (and its modifications the synoptophore and the synoptiscope). This instrument has both diagnostic and therapeutic uses. It may be used to diagnose the degree of squint, normal or abnormal correspondence as well as the fusion ability. It is easily movable. With the more recent stereoscopic charts, and if variation of light is utilized, stereoscopic ability may be well trained and may be maintained during the building of fusion amplitude and duction. No prismatic aberration is present. It may be used to train vertical imbalances. The cost of this instrument is modest. It seems important to emphasize the advantages of the synoptophore and synoptiscope in that cyclophorias may be diagnosed and partially overcome with these instruments. The variation of the illumination in these instruments is accurately gaged.

The disadvantage of the amblyoscope is that few stereoscopic charts applicable to it are available at the present time, so that variability in routine is difficult to secure. Until more stereoscopic charts are available, one can seldom depend on the amblyoscope entirely for fusion and duction training. More charts are available for the synoptophore and synoptiscope. These instruments, however, are large and expensive and will probably find their use chiefly in institutions where large numbers of patients are being trained.

As regards the more elaborate instruments in which the principle of fusing moving objects is employed, a few words are necessary. It has been my experience that most patients stimulated to overcome suppression by these instruments can do so with one of the more simple instruments, employing mirrors or prisms. It does not seem to have been proved that fusion of the moving targets in these elaborate instruments has a marked effect on the muscles and the fusion sense superior to that obtained by overcoming prisms of varying degree in the ordinary type of duction training with the stereoscope or amblyoscope.

The assertions that such instruments overcome amblyopia more rapidly than may be done with other means certainly rest on no foundation whatever, in my opinion. No instrument will take the place of prolonged monocular occlusion and atropinization for this purpose, the effect of the latter procedures being limited to a certain percentage of cases, and chiefly to those seen at an early age.

## Council on Pharmacy and Chemistry

### NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

**DEXTROSE** (See New and Nonofficial Remedies, 1934, p 270, and THE JOURNAL, April 7, 1934, p 1154)

The several accepted dextrose solutions and dextrose in physiologic solution of sodium chloride marketed in Vacoliter Containers are also supplied in Half Size Vacoliter Containers.

**DIPHTHERIA TOXOID, ALUM PRECIPITATED (REFINED)** (See New and Nonofficial Remedies, 1934, p 393)

E. R. Squibb & Sons, New York  
*Refined Diphtheria Toxoid Alum Precipitated Squibb* (See THE JOURNAL Feb 24 1934 p 605) —Also marketed in packages of ten 0.5 cc vials representing ten immunizing doses.

**BUTYN** (See New and Nonofficial Remedies, 1934, p 52)

The following dosage form has been accepted:  
*Ophthalmic Ointment Butyn 2% and Metaphen 1 10 000*. Contains 2 per cent of butyn with metaphen 1 10 000 in a base of petrolatum. Manufactured by the Abbott Laboratories, North Chicago, Illinois.

**SCARLET FEVER IMMUNITY TEST** (See New and Nonofficial Remedies, 1934, p 406)

Parke, Davis & Co., Detroit  
*Scarlet Fever Streptococcus Toxin for the Skin Test P. D. & Co.* (See New and Nonofficial Remedies 1934 p 406) also marketed in packages of one 10 cc vial containing sufficient for 100 tests.

**RABIES VACCINE** (See New and Nonofficial Remedies, 1934, p 378)

Parke, Davis & Co., Detroit  
*Rabies Vaccine (Cumming)* (See New and Nonofficial Remedies 1934 p 380) also marketed in packages of seven vials each containing one dose.

**NORMAL HORSE SERUM** (See New and Nonofficial Remedies, 1934, p 362)

Parke Davis & Co., Detroit  
*Normal Horse Serum P. D. & Co.* (See New and Nonofficial Remedies 1934 p 363) also marketed in packages containing one 1 cc rubber stoppered vial.

**DUOTAL** (See New and Nonofficial Remedies, 1934, p 150)

The following dosage form has been accepted:  
*Duotal Tablets 5 grains*  
Manufactured by Winthrop Chemical Co. Inc. New York.

**AGAR** (See New and Nonofficial Remedies, 1934, p 25)

The following dosage form has been accepted:  
*Agar Agar Shreds Reinschild*  
Prepared by the Reinschild Chemical Co. New Rochelle, N. Y.

**NEO-SYNEPHRIN HYDROCHLORIDE** (See THE JOURNAL, June 16, 1934, p 2024)

The following dosage form has been accepted:  
*Neo-Synephrin Hydrochloride Emulsion (Aromatic)*. Neo-synephrin hydrochloride 0.25 per cent, sodium benzoate 0.4 per cent, camphor 0.07 per cent, menthol 0.052 per cent, oil of red thyme 0.17 per cent in a mineral oil and water emulsion containing acacia. The product is preserved with chlorbutanol 0.5 per cent.

**PROCAINE HYDROCHLORIDE** (See New and Nonofficial Remedies, 1934, p 60)

The following dosage form has been accepted:  
*Procaine Neo-Synephrin Hydrochloride Hydrodermic Tablets*. Each tablet contains procaine hydrochloride 0.02 Gm., neo-synephrin hydrochloride 0.0003 Gm., sodium chloride 0.007 Gm. and potassium sulphate 0.004 Gm. One tablet dissolved in 1 cc. of distilled water yields a solution containing procaine hydrochloride 2 per cent, neo-synephrin hydrochloride 0.03 per cent, sodium chloride 0.7 per cent and potassium sulphate 0.4 per cent.

## Committee on Foods

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION, AND FOR GENERAL INFORMATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

### ADVERTISING OF AMERICAN HONEY INSTITUTE

**Sponsor**—American Honey Institute, Madison, Wis., is a trade association for promoting the general welfare of the honey industry, investigating its problems, and disseminating information on honey.

**Occurrence, Composition and Nutritional Values of Honey**—Honey is deposited by bees in the cells of honeycomb, which the insect forms out of wax secreted by its body. It is gathered by the bees chiefly from the nectar of flowers and the exudations of leaves. The sucrose of the nectar is almost wholly inverted into dextrose and levulose. The nectar becomes concentrated in the hive by loss of moisture. The flavors of honey are due largely to the characteristic esters found in the nectar of different flowers.

The United States Department of Agriculture definition and standards for the various forms of honey follow:

1 Honey is the nectar and saccharine exudations of plants gathered, modified and stored in the comb by honeybees (*Apis mellifica* and *A. dorsata*), is levorotatory, and contains not more than 25 per cent of water, not more than 0.25 per cent of ash, and not more than 8 per cent of sucrose.

2 Comb honey is honey contained in the cells of honeycomb.

3 Extracted honey is honey which has been separated from the uncrushed comb by centrifugal force or gravity.

4 Strained honey is honey removed from the crushed comb by straining or other means.

The nutritional values of honey are essentially those of carbohydrates as a class, it contributes little to the minerals of the diet and is devoid of vitamins.

**Analyses\*** (representative analyses for various American honeys)

## FARMER JONES BRAND PURE COUNTRY SORGHUM SYRUP

**Manufacturer**—American Syrup & Sorghum Company, St. Louis

**Description**—Sorghum syrup or concentrated, clarified sorghum cane juice.

**Manufacture**—The juice is expressed from sorghum cane stalks and is partially neutralized with dilute lime water, brought to a boil, filtered under pressure with the aid of infusorial earth, concentrated under "vacuum" to a semisyrup, heated to boiling, again filtered under pressure with the aid of infusorial earth and vegetable carbon, concentrated by boiling under "vacuum" to 81.5 per cent solids, and filled into friction top cans.

**Analysis** (submitted by manufacturer) —

**Calories**—30 per gram 85 per ounce

**Claims of Manufacturer**—For cooking, baking and table use.

## HERSHEY SYRUP GENUINE CHOCOLATE FLAVOR

**Distributor**—Chocolate Sales Corp., Hershey, Pa.

**Manufacturer**—Hershey Chocolate Corp., Hershey, Pa.

**Description**—Chocolate flavored syrup prepared from sucrose, water, cocoa and invert sugar.

**Manufacture**—The cocoa used is prepared as described for Hershey's Breakfast Cocoa (*THE JOURNAL*, March 17, 1934, p. 843) with the exception that the fat content is reduced to 9 per cent. The invert sugar ingredient is prepared by hydrolyzing sucrose with U. S. P. hydrochloric acid and subsequently neutralizing the acid with U. S. P. sodium carbonate.

Weighted amounts of the ingredients are mixed with violent beating in steam jacketed kettles. The mix is heated to boiling and flowed into filling machines, from which it is packed in steam heated cans. The canned syrup is processed at 88°C for twenty minutes.

## CAPILLARY PRESSURE AND CAPILLARY PERMEABILITY

The capillaries have generally been regarded as minute, inert, thin-walled tubules connecting the terminations of the smallest arteries with the commencement of the smallest veins and conducting blood through the body tissues in whatever quantity the arterioles might supply. During the past few years, however, a large amount of evidence has accumulated demonstrating conclusively that the capillaries perform other functions. Indeed, a recent commentator<sup>1</sup> has stated that the capillaries form one of the most important units of the entire circulatory system. Modern studies have shown that the capillaries are independently contractile and are capable of sensitive adjustment to the circulatory needs of the body tissues which they supply.<sup>2</sup> Also they perform the vital function of controlling the interchange of substances between the blood and the fluid bathing the body tissues. The importance of the capillaries as a filtering system is in part the result of the large total area of their walls. The capillaries of the muscles of an average man, for example, have a total area of approximately 6,300 square meters, or more than 3,000 times the area of the entire body surface. Furthermore, so efficient is the capillary wall as a filter that, if there were no restraining forces, the entire plasma volume of an average man would pass through the capillaries into the body tissues within ten seconds. Obviously, the movement of fluid between the blood and the body tissues depends fundamentally on the nature and permeability of the dividing membrane, the capillary endothelium. In a recent comprehensive review, Landis<sup>3</sup> has discussed the relation between capillary pressure and capillary permeability to the exchange of fluid between the blood and the body tissues.

The movement of fluid through the capillary wall depends primarily on the balance between capillary blood pressure and the colloid osmotic pressure of the blood, the former force promoting the filtration of fluid from the capillaries and the latter favoring retention or absorption. Measurements show that these two opposing physical forces are approximately equal. Capillary pressure, as determined by the long period, microcannulation technic, varies from 12 to 32 mm of mercury, colloid osmotic pressure shows a similar value equivalent to from 22 to 29 mm. By the same method, Landis has also shown that a gradient of pressure exists in the capillary itself, the pressure in the arterial portion definitely exceeding that in the venous end. Furthermore, the capillary pressure in the arterial portion exceeds the colloid osmotic pressure, thus favoring the filtration of fluid from the capillaries, whereas the reverse is true in the venous end, the opportunity for fluid absorption is thereby enhanced. In general, those factors which increase capillary pressure promote an increased filtration of fluid through the endothelium, whereas a decrease in pressure favors a retention of fluid. Such variations in capillary pressure may be elicited by changes in arterial tone, freedom of venous outflow, posture or temperature.

Another physical factor of some importance in regulating the movement of fluid through the capillary wall is that of tissue pressure. This force opposes the filtration of fluids into the tissues. Tissue pressure is effective only within limits, however, as it fails under prolonged, excessive filtration, presumably because of the imperfect elasticity of the tissues.

Complex changes in capillary pressure and capillary permeability may be initiated by such agents as variations in temperature, tissue activity and injury. Heat may increase the filtration of fluid through the capillary wall by producing capillary dilatation, by causing a rise in capillary pressure or by actual injury of the endothelium, resulting in an increased permeability of the endothelium to colloids and a consequent lowering of the effective osmotic pressure of the plasma proteins. Functional activity of the tissues induces a hyperemia and a simultaneous rise in capillary pressure, thus favoring an increased movement of fluid into the tissues. The accumulation of carbon dioxide and slight change in hydrogen ion concentration that occur during vigorous tissue activity appear to exert little if any effect on the permeability of the capillaries. Anoxemia, however, if extreme, may produce a temporary increase in permeability, which may be great enough to reduce the effective colloid osmotic pressure of the blood to half its normal value. Local injury of the capillaries may set up a series of complex responses, including vasodilatation, rise in capillary pressure, altered rate of blood flow, increased endothelial permeability and, finally, stasis. All forms of local or general edema produced by injury are due fundamentally to increased

<sup>3</sup> Landis E. M. Capillary Pressure and Capillary Permeability Physiol Rev 14 404 (July) 1934

capillary permeability with the easy passage of proteins and water through the endothelium

Is the movement of fluid through the capillary wall controlled by simple physical forces, such as those discussed, or is there an active intervention of the endothelium? This question still seems to be an open one. Apparently, many of the facts concerning fluid balance, particularly in the intact animal and in cases of clinical edema, cannot be explained in terms of simple physical forces. However, Landis has pointed out that not until the physical factors are adequately understood will the search for "vital" intervention prove productive.

In view of the many contributions elucidating the question of capillary function, most physiologists will undoubtedly agree with Landis that the capillaries form a most important unit of the circulatory system, responding individually in a delicate manner to the circulatory needs of the immediately adjacent tissues, and controlling effectively the interchange of substances between the blood and the fluid bathing the body tissues.

#### FLIES, FILTH AND BACTERIA

Real understanding of the place of flies as vectors of disease probably dates from the report of the Typhoid Commission of 1898. Thus Vaughan,<sup>1</sup> who had been one of the members of this commission, states that typhoid was less frequent among those who ate in screened mess rooms than among those who took their food in unprotected quarters. Flies were found swarming over infected fecal matter in the latrines and the same ones visiting and feeding on the food prepared for the soldiers in the mess tents. Now it is generally recognized that the house fly also plays a part in the distribution of conditions other than typhoid.

The exact role of the common fly as a carrier of disease probably varies greatly in different localities. A recent report by Parisot and Fernier<sup>2</sup> is significant in this connection. Their particular interest in the subject arose from the fact that in the rural districts of the department of Meurthe-et-Moselle, as the American expeditionary forces frequently testified, it is customary for manure heaps to be placed in front of the houses—the size of the heap bearing mute witness to the number of livestock belonging to the owner. Naturally flies are especially numerous in these districts, and although no figures are quoted by the authors it is indicated that disease, especially of the gastro-intestinal tract, is unusually frequent.

In order to make a rough estimate of flies as a potential bacterial reservoir, Parisot and Fernier carried out bacterial counts on flies caught by hand. Ten flies were placed in a bottle, each bottle having a capacity of about 20 cc. To each bottle 10 cc of sterile physiologic solu-

tion of sodium chloride was added. The flies were kept in this solution for thirty minutes and agitated frequently. With a sterile pipet yielding twenty drops per cubic centimeter, one drop of the liquid was withdrawn and diluted 1:1,000. This was seeded on gelatin or agar and the colonies were counted at the end of three days on gelatin and forty-eight hours on agar after incubation at 37 C. In order to determine the number of bacteria corresponding to one fly, the colonies given by the count had to be multiplied by 20,000 to allow for the dilution. Naturally the final figures are thus only approximate. They also carried out a special test for *B. coli* by preparing ten tubes of peptone broth treated with phenol to 1:25 per thousand. Into the first tube they introduced twenty drops of the liquid used for washing the flies. This quantity was decreased step by step to one drop of a 1:10 dilution in the ninth tube, the tenth serving as a control. The tubes were placed in the incubator for five days at 38 C and the presence of *B. coli* was determined by testing the cultures for indole production according to the method used for water analysis. On this basis the approximate number of *B. coli* per fly could be estimated.

As a result of these studies they felt that they could state that each fly without distinction of origin carried microbes ranging in number from 60,000 to over 25 million. Both in regard to total bacterial flora and number of *B. coli* carried, those flies coming in contact with unprotected manure heaps were heavier reservoirs than those caught in town flats or especially in forests. Thus in the flies caught in the immediate proximity of manure heaps the total bacterial content varied from over 10 million to over 26 million, and in all instances more than 200 *B. coli* per fly were also found. On the other extreme were the flies caught in forests, which contained from 60 thousand to 602 thousand microbes. In only one instance was a *B. coli* colony found.

An interesting part of these investigations concerned the sterilizing effects of the sun's rays on the bacterial flora of flies. When a group of flies was exposed to the sun's full rays for two hours at from 30 to 40 C the count was 160,000; in control flies there was a bacterial count of 2,540,000 colonies at the moment of capture. Similar but even more pronounced was the drop in bacterial flora of flies caught near manure heaps.

Since the work of the Typhoid Commission there has never been any doubt that flies carrying pathogenic micro-organisms can readily seed foodstuffs. The truth is again demonstrated by the results of Parisot and Fernier. After only one minute contact between the fly *Musca domestica* and an ordinary agar plate, ninety-three colonies were counted after twenty-four hours. Furthermore, contact of only a few minutes was found sufficient to seed milk, from which enormous bacterial proliferation could occur even after two hours.

While it is true that these studies emanate from rural districts in France, renewal of the knowledge of the

bacteria carrying ability of flies may be particularly apropos in view of the widespread gastro-enteritis and summer diarrhea in this country this year

### THE AGLOMERULAR KIDNEY

Older pathologists believed that the ultimate fate of the kidney glomerulus in chronic nephritis is fibrinous degeneration with the formation of a permanent hyaline scar. The ratio of normal glomeruli to hyaline scars, therefore, was taken as a reliable index to the extent of the kidney degeneration. Doubt as to the validity of this assumption has recently been expressed by pathologists, who conceive the possibility of complete absorption of degenerated glomeruli without the formation of permanent scars.

Joelson Beck and Moritz<sup>1</sup> of the Laboratory of Surgical Research, Western Reserve University School of Medicine, for example, made histologic sections of dog kidneys at varying intervals after unilateral urethral obstruction. From these sections they inferred a probable reduction in the total number of glomeruli which was greater than that indicated by the percentage of hyaline glomerular remnants.

This inference is confirmed by Moritz and Hayman,<sup>2</sup> who have applied to the problem some of the newer methods of quantitative glomerular assay. To count the total number of glomeruli in a kidney, the Cleveland investigators perfused intact kidneys with physiologic solution of sodium chloride followed by a prussian blue injection mass. Blocks of the injected kidneys were taken for routine histologic study. Aliquot parts of the same kidneys were macerated in 50 per cent hydrochloric acid. Since the injected glomeruli are resistant to this acid, they appear as deeply stained blue balls in the digestates. The number of injected glomeruli, therefore, is counted by means of a ruled watch glass. From this number the number of noninjected normal glomeruli and of recognizable hyaline scars is readily determined. Applying this technic, the Cleveland investigators found that, within sixty days after partial urethral obstruction plus unilateral exposure to x-rays in rabbits as many as 70 per cent of all glomeruli may be completely absorbed from the exposed kidney without leaving microscopically demonstrable hyaline masses. In presumably normal human kidneys they found the average number of apparently normal glomeruli to be 1,282,800. In chronic renal disease they found several cases in which the total number of demonstrable glomeruli was reduced to 500,000 or even to 300,000 per kidney. Only 2 to 6 per cent of this number might be represented by hyaline or fibrinous masses. From one half to two thirds of all glomeruli of these kidneys had apparently disappeared without leaving microscopically demonstrable traces.

## Current Comment

### PRACTICAL PATRIOTISM

The Department of Health of New Haven, Conn., has instituted a campaign to prevent the sale of fireworks for the Fourth of July. On the cover of the July bulletin of the department<sup>1</sup> is a tabulation of Fourth of July accidents from fireworks for New Haven and Bridgeport for the last six years. In 1929 New Haven had fifty-one such accidents and Bridgeport seventy-four. The following year New Haven had 143 and Bridgeport 211. In that year Bridgeport adopted an ordinance prohibiting the sale and use of fireworks and New Haven rejected a similar ordinance. In the following four years New Haven had 152, 79, 83 and 104 accidents, while Bridgeport had 7, 6, 4 and 2. Such graphic representation is more than convincing of the desirability of similar ordinances to control elsewhere the unnecessary damage resulting from patriotic celebrations of the nation's independence.

### CYTOPLASMIC ANTIBODIES

The recently developed technic for obtaining practically undiluted cytoplasm for immunologic study should yield valuable immunochemical data and modify many theories of specific allergy and specific immunity. The well confirmed fact that certain experimental allergies and immunities are not accompanied by demonstrable "antibodies" in the blood stream and the recently suggested possibility that homologous intracellular and extracellular "antibodies" may be of different specificities<sup>1</sup> demonstrate the need for some such cytoplasmic technic. Study of intracellular specificities has usually been attempted by extracting minced tissues with physiologic solution of sodium chloride, glycerin, alcohol or other solvents, or by perfusing intact organs with Ringer's solution. Such techniques at best yield but dilute solutions of the intracellular products. To obtain relatively undiluted cytoplasm, therefore, Seegal and Khorazo<sup>2</sup> of Columbia University expressed tissue juices by means of a hydraulic press. The tissues were first cut into small fragments and then minced with a large volume of filter paper. The resulting grumose mass was wrapped in cheese-cloth and subjected to a pressure of about 16,000 pounds to the inch. About 15 or 20 per cent by weight of the tissue was recovered in the expressed juice. The pressure was found sufficient to break up all tissue cells, no intact cells being demonstrable in the residue. As a sample of the application of this technic, the Seegals<sup>3</sup> made a quantitative study of the cytoplasmic antibodies in certain hypersensitive tissues. Following unilateral injection of typhoid vaccine into the anterior chamber of the rabbit's eye, for example, the local specific agglutinin titer of the press juice at times was from two to four

times that of the blood stream and from ten to twenty times that of the aspirated aqueous humor. Occasionally intracellular agglutinins were demonstrated with no demonstrable agglutinins in the adjacent extracellular fluids.

## Medical Economics

### SAN DIEGO CENTRAL CLINIC SERVICE

The Central Clinic Service of San Diego originated with a suggestion from the Health Council of the Community Welfare Council. The objective was to provide an organized method of meeting the medical needs of the resident indigents and others whose incomes would permit either a part or full pay service. The Central Clinic Committee is composed of representatives of the county medical society, the community welfare council, the county and city health departments, county hospital advisory board, health and development department of the city schools, navy relief, Mercy Hospital and San Diego Hospital. An executive secretary and staff operate under the supervision of the board of directors. The principal functions of this executive staff are to conduct a social service investigation to determine resources and fees to be charged and to direct patients to the physician of their choice or, if no choice exists, to a list of physicians in alphabetical order.

Patients come to the Central Clinic Service from four main sources, the physician, hospital, clinic or by direct application of the patient himself. By far the most important source is the physician, as is shown by table 1, covering the year 1933 and first six months of 1934.

TABLE 1—Sources from Which Patients Came to Clinic  
Year 1933

	Number	Per Cent
Referred by physicians	541	40.7
Referred by self	219	15.4
Referred by county	247	18
Referred by Mercy Hospital	87	6.3
Referred by San Diego Hospital	20	1.3
Referred by school clinic	103	7.6
Referred by other agencies	133	9.8
Jan 1 1934 to June 30 1934		
Referred by physicians	328	50.7
Referred by self	106	16
Referred by county	68	10.3
Referred by Mercy Hospital	26	3.9
Referred by San Diego Hospital	5	0.7
Referred by school	68	10.3
Referred by other agencies	54	8.2

There has been a continuous growth in the work of the clinics and in the proportion of families that are able to pay full or part fees.

TABLE 2—Distribution of Wages

241 or 53.8%,	of this group and 30.4% of the total number of families earned below \$75 monthly
140 or 31.3%,	of this group and 17.6% of the total number of families earned between \$75 and \$110 monthly
37 or 7.1%,	of this group and 4% of the total number of families earned between \$110 and \$125 monthly
10 or 2.2%,	of this group and 1.3% of the total number of families earned between \$125 and \$130 monthly
25 or 5.6%,	of this group and 3.1% of the total number of families earned between \$130 and \$135 monthly

The fees collected in 1933 amounted to \$22,850.39. In the first six months of 1934 they were \$18,888.56. The character of the population served is shown by the fact that, of 794 families given reduced fees in 1933, 448, or 56.4 per cent were earning regular wages of some amount. The distribution of these wages is given in table 2.

Information on which this article is based is obtained from the Bulletin of the San Diego County Medical Society (Jan. 19 1934) and from material furnished by the executive secretary of the clinic.

Of the 794 families, 346 earned irregular wages or had other sources of income such as compensation, commission, pensions, or were unemployed. These were distributed as in table 3.

There are 182 physicians in the San Diego County Medical Society who agreed in January 1933 to take Central Clinic Service patients.

"As much time as we know must be spent by all families in 'making ends meet' it has been surprising to learn how few of them have actually figured medical costs into monthly or annual budgets.

"One of the important factors in the work of the Central Clinic Service has been to analyze expenditures with heads of families, to make suggestions and to plan monthly allotments, for medical service. It has been gratifying to find that this service is successful and that families have profited by the experience.

TABLE 3—Income of Families Given Reduced Fees

129 or 37.3%,	of this group or 16.2% of the total number of families were unemployed
122 or 35.3%,	of this group or 15.4% of the total number of families earned irregular wages
16 or 4.6%,	of this group or 2% of the total number of families had compensations
31 or 8.9%,	of this group or 3.9% of the total number of families earned commissions
48 or 13.9%,	of this group or 6% of the total number of families had pensions

"'Steering' patients is one of the real jobs of the Central Clinic Service. The 20 per cent of patients sent to physicians at full fee were not all bargain hunters who came to the agency seeking lowered fees. Many of them were persons who were at a loss how to arrange for adequate care. The explanations of the parts played by diagnostic and treatment service of the laboratories, x-ray departments, specialties of all kinds has been important. Interpretation of the social situation of the patient to the physician undertaking the treatment has been equally important.

"Many cases have been undertaken as Central Clinic Service cases only to find that, once the service has been arranged, the patients can make their own further plans. Having assurance that costs could be controlled if necessary has been a factor in the patients' undertaking diagnostic or treatment procedures.

"Gratitude to the referring physician and to the whole service has been the outstanding point of view of patients and their families.

"The chance to have the service of the family physician or the specialists within fees that they can pay has given many patients real gratification. It has meant that the values of the patient-physician relationship have been preserved, that medical service of the finest type has been available to all members of this community.

"If social problems arise, the patients are referred to social agencies which can assist or advice is given by the Central Clinic Service workers. Cooperation between agencies has been a policy always observed.

"Each case is approached from the point of view of the family in relation to the present medical problem. The record kept is a modification of the usual medical-social face-sheet used in most case work practice. The patient shares in making the plan, he examines his own resources and those of his family. Both assets and liabilities, social and financial, are considered, situations are faced frankly. Relatives who can assist are asked to do so. But patients are taken into the plan and the success depends on the skill of the social worker in establishing in the patient the sense that he is making his budget and at his own standard of living.

"Policies regarding eligibility for reduced fees are based necessarily on the medical service involved. A family which would not be given reduced fees for minor dental service might be eligible for major surgery.

"Life insurance is generally considered an asset. However, if the family is overinsured on the general family budget the cashing of some policies is encouraged. This is true, too, if the family is obviously letting present needs suffer to save for the indefinite demands of the future.

"The owning of homes or the buying of moderately priced homes does not in any case exclude patients from the service. The purchase or retention of property for income or speculation, however, places the family in another category.

"The owning of automobiles does not exclude from service, but the purchase of expensive cars or luxuries in furniture and household equipment does.

"Reduction of fees is on a sliding scale and these above-mentioned factors are all taken into consideration.

"Patients are quick to recognize that the purpose of the Central Clinic Service is to give them adequate medical service and the cooperation of the majority of the families is splendid.

"The year shows that the applicants are made up of sincere persons, occasionally misguided, occasionally querulous, as a result of ill health or poverty, but eager for the most part, to be self dependent.

"The plan of fee setting for cases requiring hospitalization has been to use the part-pay hospital fee as a basis for the surgeons' fee and to pay the anesthetist and assistant in proportion.

"The original plan of fees outlined in Dr. Hall Holder's study of Central Clinic Service published in February 1933 is in use now. The basic surgical fee to hospitals is \$3.50 per day including operating room service, routine medicines, and a minimum supply of dressings. Four-bed wards are used except in those cases where a private room is considered necessary by the physician. Private-duty nursing has been on the same basis.

"Nursing service has been limited to a few days or nights and patients, for the most part, have accepted that the physician's judgment shall determine the type of nursing service required.

"It has been almost a universal experience that if requests are made for special services, not medically necessary, the patients are not within the part-pay group.

"Part of the work of the Central Clinic Service is to plan the surgical service with the patients, outlining the facilities involved, explaining and interpreting those necessary for the welfare of the patients. This is an important and detailed social service function.

"The secretary and the board of directors cannot speak too highly of the attitude of all cooperating agencies. The Central Clinic Service average of twelve hundred telephone calls a month bespeaks the constant relationship of the service with physicians, hospitals, druggists, ambulance service, and nursing service in working out the individual cases.

"Both the executive-secretary and the field worker are members of the American Association of Social Workers and are 'registered social workers' under the standards recently adopted by the California Conference of Society Work."

The reception of the plan by the community may be judged to some extent from the following editorial in the San Diego Union, Aug. 20, 1934:

"San Diego County's medical society undertook a new experiment in cooperating with its members' clientele some eighteen months ago when it established the Central Clinic. Now, after an extremely encouraging beginning, the society asks local employers to help extend the service.

"As many readers will recall from published reports, the Clinic was designed to meet the need of persons who wished to pay their way but who could not carry the full cost of medical or surgical treatment. To solve this problem an office was established under a competent social worker who was responsible for fixing the amount that any particular applicant could pay. On their part approximately 65 per cent of the Society's members agreed to abide by the decision of the central office.

"The experiment is a success. It has been widely discussed and, we are informed, has been copied in other communities. Viewed from the layman's point of view, this success is understandable. Obviously the physicians made a real sacrifice when they surrendered some of their freedom of action by accepting the aid of a third party in arriving at an equitable fee in any given instance.

"This sacrifice should win them a sympathetic hearing in calling upon local employers to cooperate by either making loans to their employees against future wages or by working

out some other means of spreading the cost of emergency treatment over a considerable period.

"All parties admit that the cost of medical care is sometimes prohibitively high. We congratulate the physicians in attacking this problem locally. And we believe that they have made sufficient progress to justify their request that business concerns help broaden the Clinic's usefulness."

## Association News

### MEDICAL BROADCASTS

#### Columbia Broadcasting System

The American Medical Association broadcasts on a Western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45, central daylight saving time. The next three broadcasts will be as follows:

September 27 Swimming Pool Sanitation, J. F. Hammond, M.D.  
October 4 Autumn Leaves, W. W. Bauer, M.D.  
October 11 Multiple Births, W. W. Bauer, M.D.

#### National Broadcasting Company

Through the courtesy of the National Broadcasting Company, the American Medical Association will resume broadcasting over the blue network on Oct. 2, 1934. Broadcasts will be scheduled each Tuesday afternoon from 4 to 4:15, central standard time. The number of stations, and their identity, to which this program will be available will be published in THE JOURNAL as soon as available. Topics and speakers for October are as follows:

October 2 Curiosities of Medicine, Morris Fishbein, M.D.  
October 9 School Health Problems, W. W. Bauer, M.D.  
October 16 Research in Medicine, A. C. Ivy, M.D.  
October 23 Reading About Health, W. W. Bauer, M.D.  
October 30 'Diphtheria Must Go', W. W. Bauer, M.D.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

### CALIFORNIA

**Sale of Dinitrophenol Restricted**—Physicians licensed to practice medicine in California will have sole charge of the distribution of dinitrophenol in the future, in accordance with a resolution adopted by the state department of health, August 20. Since dinitrophenol has already been responsible for a number of deaths, the board forbids any one other than a licensed physician to prescribe, dispense or sell this product.

**Gifts for Research**—Among gifts presented to the University of California recently were \$2,500 from C. S. Howard and \$800 from other citizens of San Francisco for support of research on poliomyelitis now in progress at the George Williams Hooper Foundation under the direction of Karl F. Meyer, Ph.D. A gift of \$5,000 from the Rockefeller Foundation for the study of chemical aspects of vitamins and hormones under Dr. Herbert M. Evans, Berkeley, was also announced.

**Society News**—At a joint meeting of the San Francisco District Dental Society and the San Francisco County Medical Society, September 4, the following dentists presented the program: Leland E. Carter, D.D.S., "Dental Radiographic Interpretation"; A. W. Ward, D.D.S., "Focal Infection"; and Henley Miller, D.D.S., "Aspects of Oral Surgery." Dr. Walter L. Biering, Des Moines, Iowa, President, American Medical Association, addressed the Alameda County Medical Association, September 6, on "The Educational Function of the American Medical Association."—A symposium on epidemic poliomyelitis formed a part of the program before the health officers' section of the American Public Health Association at Pasadena, September 3-6. The speakers included Drs. Jay D. Dunshee, state health officer, James P. Leake of the U. S. Public Health Service, and Karl F. Meyer, Ph.D., San Francisco.

## ILLINOIS

**Encephalitis Continues to Increase**—For the week beginning September 3, forty-nine new cases of epidemic encephalitis were reported in Illinois, indicating a new high weekly prevalence level for the state this season, the Illinois State Department of Health reports. The department points out however that, since this total is only slightly higher than the forty-seven cases for the previous week, the peak wave has probably been reached. It was stated that three epidemic centers, Fulton, Peoria and Vermilion counties, reported eleven, twelve and seventeen cases respectively for the week of September 3, giving a total of forty. Elderly persons continue chiefly to be the victims, although a number of cases have been reported among children and young adults.

**Society News**—Dr Sidney O Levinson, Chicago, discussed infantile paralysis before the Iroquois County Medical Society at Watseka, September 13.—The Pike County Medical Society was addressed in Pleasant Hill, July 26, by Drs Kirk Shawgo on appendicitis, Milton E. Bitter, normal pregnancy, its care and delivery, Frank Cohen, allergy, and Walter M. Whitaker, diarrhea in children. All are from Quincy.—Dr Frederick B. Balmer, Chicago, discussed "Medical Economics as an Essential Part of a Physician's Education" before the Peoria City Medical Society at its annual fish fry at the Illinois Valley Yacht and Canoe Club, September 5.—At a meeting of the Adams County Medical Society in Quincy, September 10, Dr Clayton J. Lundy, Chicago, discussed the treatment of rheumatic disease. A motion picture on "The Mechanism and Electrocardiographic Registration of the Normal Heart Beat" was also shown.—Dr William Thalheimer, Chicago, addressed the Fulton County Medical Society, August 15, on poliomyelitis.

## INDIANA

**University News**—The medical library of Indiana University recently received 130 volumes from Dr Joseph N. Study, Cambridge City. Six volumes on internal diseases and a separate medical index were contributed by Mr Robert R. Litz of the Medical and Dental Equipment Exchange, Indianapolis.

**Society News**—Dr Oscar N. Torian, Indianapolis, discussed childhood anemias before the Carroll County Medical Society at Brimhurst, August 17.—Dr John H. Warvel, Indianapolis, addressed the Clinton County Medical Society in Frankfort, September 6, on diabetes.—Dr Jean P. Pratt, Detroit, addressed the Tippecanoe County Medical Society at Lafayette, September 13, on "Endocrine Disturbances Peculiar to Women."

## IOWA

**Society News**—At a meeting of the Van Buren County Medical Association at Keosauqua, August 10, Drs John H. Peck, Des Moines, discussed "Our Responsibility in Tuberculosis," and Daniel J. Glomset, Des Moines, "Coronary Disease."—Dr Owen H. Wangenstein, Minneapolis, among others, addressed the Scott County Medical Society, July 26, on "Diagnostic and Therapeutic Considerations in the Management of Acute Abdominal Lesions."—Speakers before the annual meeting of the Dallas-Guthrie Counties Medical Society and its women's auxiliary in Woodward, August 2, included Drs Thomas A. Burcham, Des Moines, on "Problems of the State Society," and Stuart W. Harrington, Rochester, Minn., "Diagnosis and Surgical Treatment of Carcinoma of the Breast."—Dr James C. Donahue, Centerville, addressed the Davis County Medical Society in Bloomfield, July 11, among others, on "Fracture of Cervical Vertebrae."—At a meeting of the Floyd County Medical Society in Charles City, June 26, Dr James B. Miner Jr read a paper on "Clinical Types of Nocturnal Dyspnea."—Dr Oliver J. Fay, Des Moines, among others, addressed the Cerro Gordo County Medical Society, August 14, on principles of medical practice.

## KANSAS

**Dr Mills Appointed Editor**—Dr William M. Mills, Topeka, has been appointed editor of the *Journal of the Kansas Medical Society*, succeeding Dr Earle G. Brown. He will be assisted by a newly appointed editorial board, the selection of which is now being made by the executive secretary committee.

**Society News**—Dr Walter H. Nadler, Chicago, will speak before the Shawnee County Medical Society, October 1, on "Diagnosis and Treatment of Diabetes Mellitus."—The Wyandotte County Medical Society was addressed, September 18, by Dr William W. Abrams on hypoglycemia. The society was addressed by Dr Charles F. Taylor, Norton, on tuberculosis and hospital facilities.

## KENTUCKY

**Course in Pediatrics**—A graduate course in pediatrics will begin at the Children's Free Hospital, Louisville, October 10, and continue for ten weeks, under the auspices of the American Academy of Pediatrics. A fee of \$5 will be charged for the course. In addition to the lectures and round table discussions, the newer diagnostic and therapeutic measures will be demonstrated.

**Society News**—At a meeting of the Mason County Medical Society, July 26, Dr Granville S. Hanes, Louisville, discussed rectal conditions.—A recent session of the Pulaski County Medical Society was addressed by Dr Louis Frank, Louisville, on "Cancer of the Uterus," and Dr Aura J. Miller, Louisville, the pathology involved.—Speakers before the Seventh Councilor District Medical Society at Crab Orchard, July 26, included Drs Winston U. Rutledge, Louisville, on "Fungal Infections of the Skin," and Fred W. Rankin, Lexington, "Lesions of the Large Bowel and Rectum." A resolution was passed at this meeting commemorating the death of Dr James B. Kinnaird, Lancaster.

## MARYLAND

**Typhoid Carrier Discovered**—In August, typhoid in a young man was reported to the Baltimore Health Department. Investigation disclosed no probable source of infection, but inquiry in the patient's family revealed that his mother had had the disease about forty years previously. Specimens proved positive for typhoid.

**Vaccination Law Enforced**—The Baltimore Health Department has requested school authorities to adhere strictly to the vaccination law which forbids teachers to accept a pupil who does not present a certificate of successful vaccination. Parents have been urged to consult their family physicians and in those cases in which it is necessary a list of clinics has been furnished.

## MICHIGAN

**New Health Unit**—With headquarters in Hillsdale, the new health unit for Hillsdale County began to function, September 1. The W. K. Kellogg Foundation sponsors the unit with the cooperation of the state and county. Dr Edward G. McGavran is director of the unit.

**Society News**—Dr Frank G. H. Maloney, Ironwood, was chosen president of the Upper Peninsula Medical Society at its recent annual meeting in Ironwood, succeeding Dr John J. Walch, Escanaba. The next annual convention will be held in Iron Mountain, with the Dickinson-Iron County Medical Society as host.

**Farewell Gifts to Dr Warnshuis**—Organizations with which Dr Frederick C. Warnshuis, formerly of Grand Rapids, has been associated for many years presented him with gifts on his departure recently for California to become secretary of the California Medical Association. The Kent County Medical Society gave a farewell party, at which a radio was presented to Dr Warnshuis. The council of the Michigan State Medical Society gave him a wrist watch and the house of delegates a traveling bag, in recognition of his long service as secretary of the society. In addition, the house of delegates adopted a resolution expressing appreciation of his work as secretary and editor of the society's journal and as secretary of the State Board of Registration in Medicine. The staff of Butterworth Hospital, Grand Rapids, also entertained Dr Warnshuis at a dinner and presented him with a desk set.

## MINNESOTA

**Graduate Course**—The University of Minnesota Medical School, Minneapolis, will offer a short graduate course for physicians, September 24-25. Half days will be devoted to a consideration of diabetes, tuberculosis, the heart and a fracture clinic, while Monday evening will be given over to a discussion of cancer. The fracture clinic will be given by the staff of the Minneapolis General Hospital.

**Society News**—Speakers before the Wabasha County Medical Society at Lake City, July 5, included Drs Rudolph C. Radabaugh, Hastings, on "Pioneer Medical Conditions in the County," and "Fecal Impaction Following Cholecystitis"; Francis J. Savage, St. Paul, "The Work of the State Medical Association During the Past Ten Years," and "Fractures of the Humerus"; Emory Covell Bayley, Lake City, "Report of Operation for Strangulated Hernia on a Four Weeks Old Premature Infant," and J. Grafton Love, Rochester, "Treatment of Head Injuries."

**Southern Medical Meeting**—The Southern Minnesota Medical Association held its annual meeting at Mankato, August 13. Speakers included the following physicians:

Edward T. Evans Minneapolis Backache  
Lee W. Barry St. Paul, Dysmenorrhea  
Owen H. Wangenstein Minneapolis Abdominal Pain  
Henry W. F. Woltman Rochester Headache  
Louis A. Brunsting Rochester Itching  
Philip W. Brown Rochester Diarrhea  
Gilbert J. Thomas Minneapolis Hematuria  
Arlie R. Barnes Rochester Irregular Pulse  
Thomas J. Kinsella Oak Terrace Surgery in Pulmonary Tuberculosis  
Edward L. Tuohy, Duluth Management of Essential Hypertension  
Arthur E. Hertzler Hilstead, Kan., Functional Disorders of the Gastrointestinal Tract  
Joseph C. Michael and Burton P. Grimes Minneapolis End Results in the Malarial Treatment of Dementia Paralytica

Clinics and demonstrations were also a part of the program. Dr. Sidney A. Slater, Worthington, was elected president, Drs. Charles W. Mayo, Rochester, and Joseph C. Michael, Minneapolis, vice presidents, and Harold C. Habein, Rochester, secretary.

### NEW MEXICO

**Public Health Meeting**—Dr. Eugene P. Simms, Alamo, was elected president and Dr. Walter E. Kaser, Las Vegas, vice president of the New Mexico Public Health Association at its annual meeting recently. A resolution adopted at the meeting empowered Dr. John Rosslyn Carp, Santa Fe, state health officer, to appoint a health education committee to disseminate information about public health problems of the state. George I. Sanchez, who was elected president of the committee at a meeting in Albuquerque, August 14, and Drs. Carl Mulky and Charles Howe Eller have accepted membership on the committee and others will include representatives of newspapers, parent-teacher associations, the Catholic Church and parochial schools and the Protestant churches.

### NEW YORK

**Society News**—Dr. William Justus Merle Scott addressed the Medical Society of the County of Monroe, Rochester, at a special clinic at Strong Memorial Hospital, August 16, on "Treatment of Gastric Versus Duodenal Ulcers."—Dr. Stuart B. Blakely, Binghamton, spoke on "Psychology in Obstetrics" before the Broome County Medical Society, September 11.

#### New York City

**Dr. Holden Made Professor Emeritus**—Dr. Frederick Clark Holden, who has been associated with University and Bellevue Hospital Medical College since 1919, has retired as professor of obstetrics and gynecology and has been appointed professor emeritus. Dr. William Emery Studdiford Jr. has been promoted to professor of obstetrics and gynecology, effective September 1. Dr. Richard Charles Bodo has been made associate professor of pharmacology.

**Survey of Slum Areas**—An inventory of real property in Manhattan by the Tenement House Commissioner and New York City Housing Authority has brought out the fact that nearly a fourth of the families lack ordinary sanitary conveniences. The figures show that 157,749 homes are without central heating plants, 120,622 have no tub or shower bath, 60,742 are without running hot water and 11,576 lack private indoor toilets. These conditions were found not only on the East Side, the recognized tenement district, but in other and supposedly more prosperous sections as well.

**Hospital News**—The Beth David Hospital has purchased the Manhattan General Hospital and expects to occupy it within a year. With the additional ward space to be provided the capacity of Beth David Hospital will be increased to 250 beds. This institution has been at its present location since 1910. The medical staff of the Jewish Memorial Hospital will be reorganized and enlarged in anticipation of the completion of its new building, according to *New York Medical Week*. Information concerning staff positions and application blanks may be obtained by writing Jacob Carlinger, superintendent. The address is Dyckman Street and River Road.

**Course in Dental Medicine**—The fourth lecture course in dental medicine will open at Mount Sinai Hospital, October 9, with Dr. Ernst P. Boas as the speaker on "Physical Diagnosis: Clinical Observations in Relation to Dental Conditions." The following completes the series:

Dr. Samuel H. Geist November 13 Importance of Prenatal Care  
Harry Sobotka Ph.D. December 11 Chemistry of the Saliva and Its Influence on the Tissues  
Dr. Paul Klemperer January 8 Histopathologic Studies of the Dental Tissues  
Dr. Philip Finkle February 12 Arthritis and the Teeth  
Dr. Albert A. Berg March 12 Treatment of Oral Surgical Lesions from the Viewpoint of the General Surgeon  
Harry A. Goldberg D.D.S. April 9 Dental Infections Their Significance and Treatment—Local and Systemic

### NORTH CAROLINA

**Outbreak of Malaria**—About 500 persons have been stricken with a malignant form of malaria in Camden County, newspapers reported August 6. Bruce Mayne of the U. S. Public Health Service and Dr. Joseph C. Knox, Raleigh, state epidemiologist, went to the scene to investigate.

**Society News**—Drs. Margaret Caroline McNairy, Lenoir, and Glenn R. Frye, Hickory, addressed the Catawba Valley Medical Society, July 10, on antepartum care and late toxemias of pregnancy, respectively. Dr. John D. Rudisill, Lenoir, discussed a recent outbreak of anthrax in and near that town.

**Personal**—Dr. Robert S. McGeachy, Greenville, has resigned as health officer of Pitt County to accept a similar position in Halifax County. Dr. Zack P. Mitchell, Weldon, has transferred from Halifax to Vance County. Dr. Needham E. Ward Jr., Durham, was named temporary health officer of Pitt County.

### OHIO

**Memorial for Dr. Shipley**—Funds are being solicited by a civic committee of Canton to equip an emergency unit at the Aultman Hospital, Canton, as a memorial to the late Dr. Ralph T. Shipley, for many years chief of staff of the institution. Dr. Shipley died July 7. The committee hopes that all contributions will be received by October 1.

**Dr. Hertzler Lectures**—Dr. Arthur E. Hertzler, professor of surgery, University of Kansas School of Medicine, will deliver the annual graduate lectures of the Academy of Medicine of Lima and Allen County, October 8-12. Ten lectures comprise the series which will be devoted to "Surgical Pathology," "Surgical Diagnosis" and "After-Care of Surgical Cases."

**Poetry Contest**—The Academy of Medicine of Cleveland announces that a poetry contest for members will close, November 10, the winner to receive a silver cup. The material may be presented in any of the classic forms but must not exceed forty lines, it must be the original work of the candidate. All contributions should be sent to the editorial board, which has designated an outside authority to serve as judge.

**Health at Columbus**—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended September 1, indicate that the highest mortality rate (161) appeared for Columbus and that the rate for the group of cities as a whole was 93. The mortality rate for Columbus for the corresponding period last year was 108 and for the group of cities, 96. The annual rate for eighty-six cities for the thirty-five weeks of 1934 was 116, as against a rate of 11 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

### OREGON

**State Medical Meeting at Corvallis**—The sixtieth annual meeting of the Oregon State Medical Society will be held at Corvallis, September 27-29, with headquarters at the Hotel Benton. Guest speakers will be:

Dr. William C. Woodward Chicago director Bureau of Legal Medicine and Legislation American Medical Association The Pending Cullis Initiative Measure  
Dr. Walter L. Bierring Des Moines Iowa President American Medical Association Heart Disease and the General Practitioner  
R. R. Parker U. S. Public Health Service Hamilton Mont. Rocky Mountain Spotted Fever  
Dr. Sterling Bunnell San Francisco Primary Operation for Intracapsular Fracture of the Femoral Neck

Oregon physicians who will participate include:

Dr. Andrew J. Browning Portland Practical Considerations of Glaucoma  
Dr. Ernest A. Woods Ashland Infections of the Nose and Throat with Reference to Foreign Protein Therapy  
Dr. Joseph B. Bilderback Portland Vitaminized Foods  
Dr. John Guy Strohm Portland Acute Gonorrheal Infection in the Male  
Dr. Charles E. Hunt Eugene, Recent Trends in Obstetric Analgesia A National Survey  
Dr. Albert W. Holman Portland, Functional Endocrine Disturbances of the Female Sex Organs  
Dr. T. Homer Coffey Portland Treatment of Angina Pectoris  
William Levin Dr. P.H., Portland Tularemia and Its Incidence in Oregon  
Dr. Arthur J. McLean Portland Fracture of the Vertebrae with Spinal Cord Lesions Indications for Laminectomy

Dr. Woodward will also address a joint meeting of civic clubs on "Why Regulate the Practice of the Healing Arts?" The eighth annual golf tournament will be held at the Corvallis Country Club, Saturday afternoon, and the annual banquet will be Friday evening at the Hotel Benton.

## PENNSYLVANIA

**State Medical Meeting at Wilkes-Barre**—The eighty-fourth annual session of the Medical Society of the State of Pennsylvania will be held in Wilkes-Barre, October 1-4. Guest speakers will be

- Dr. Frederick C. Holden, New York, Why Women Die in Childbirth—Some of the Reasons and Remedies
- Dr. George W. McCoy, Washington, D. C., Research Work of the National Institute of Health
- Dr. C. Macfie Campbell, Boston, Psychiatry from the Standpoint of the General Practitioner
- Dr. Herrman L. Blumgart, Boston, Clinical Management of Patients Before and After Total Ablation of the Thyroid for Chronic Heart Disease
- Dr. Jerome P. Webster, New York, Deforming Scars: Causes, Prevention and Treatment
- Dr. John Sbelton Horsley, Richmond, Va., Diagnosis and Treatment of Cancer of the Large Bowel
- Dr. Charles N. Spratt, Minneapolis, Glaucoma: Results with Sclerecto-Iridodialysis
- Dr. William V. Mullin, Cleveland, The Blood in Otolaryngology
- Dr. I. Newton Kugelmass, New York, Clinical Control of Hemorrhagic Disturbances in Childhood
- Dr. Arthur F. Abt, Chicago, Leukemia in Childhood
- Dr. Howard Fox, New York, Diseases of the Tongue
- Dr. George G. Smith, Boston, Treatment of Tumor of the Bladder

The annual golf tournament will be held at the Fox Hill Country Club, Pittston, Monday, October 1.

## Philadelphia

**President's Message to County Society**—Dr. Seth A. Brumm, president of the Philadelphia County Medical Society, in an address before the board of directors of the society at the opening of the season's activities, September 12, outlined recommendations of policy for the coming year. Dr. Brumm asserted that it is the duty of the society to uphold the ten principles of medical practice adopted by the House of Delegates of the American Medical Association at the eighty-fifth annual session in June. He said "the vigorous national policy of the American Medical Association must be followed by equally vigorous and intelligent economic policies by every state society, and the policies of the state societies must be supported and augmented by vigorous county medical society programs." In this connection he recommended closer cooperation between the medical profession and the lay health agencies of Philadelphia. "I believe the time has come when these agencies should be properly coordinated in order that their activities may be always intelligently directed by reason of the medical profession acting in an advisory capacity and with the added thought that all medical activities in Philadelphia should be and always remain under the jurisdiction of the medical profession," he declared. In a discussion of the civic relations of the society Dr. Brumm urged cooperation with the city department of health and touched on treatment of indigent patients at hospital clinics. It is especially important, he said, that hospital staffs guard against outside interference in order that the civic relation between the medical profession and the public shall remain at all times above reproach. In connection with continued education of the physician, Dr. Brumm recommended appointment of an advisory committee of medical educators to work with the society's committee on education in the formulation of a definite policy for efficient medical instruction adapted to the needs of the members.

## TENNESSEE

**University News**—Among changes in faculty positions announced by Vanderbilt University School of Medicine are the promotions of Dr. Seale Harris Jr. to associate professor of medicine and Jack M. Wolfe, Ph.D., to assistant professor of anatomy. The university also announces the publication in two volumes of the lectures delivered by Sir William B. Hardy and Dr. Francis R. Fraser in 1931 and 1933 under the Abraham Flexner Lectureship.

**Health at Nashville**—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended September 8, indicate that the highest mortality rate (184) appears for Nashville and that the rate for the group of cities as a whole was 101. The mortality rate for Nashville for the corresponding week of last year was 165 and for the group of cities, 94. The annual rate for the eighty-six cities for the thirty-six weeks of 1934 was 115, as against a rate of 11 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

**Society News**—Drs. Walter C. Alvarez and Frederick A. Willius, Rochester, Minn., addressed a special meeting of the Nashville Academy of Medicine and Davidson County Medical Society, July 31, on "Diagnosis and Treatment of Diarrhea" and "Newer Concepts of Coronary Disease," respectively. At the meeting of the Chattanooga and Hamilton County Medical Society, September 6, Dr. Robert C. Robertson, Chattanooga, spoke on Direct Fixation on Hip Fractures. Dr. Jewell M. Dorris, Memphis, addressed the Giles County Medical Society, July 26, on "Diagnosis and Treatment of Head Injuries." Speakers at the July meeting of the Hardin Lawrence-Lewis-Perry-Wayne Counties Medical Society, Savannah, July 31, were Drs. John H. Tilley, Lawrenceburg, on "Acute Abdominal Symptoms Arising from Ovarian Pathology," Phillip C. Schreier, Memphis, "Treatment of Cervical Erosions and Its Relationship to Cancer," and Walker L. Rucks, Memphis, "Infant Feeding." Dr. James E. Cottrell, Philadelphia, addressed the Knox County Medical Society, July 10, on infantilism and dwarfism.

## VIRGINIA

**Typhoid from Spring Water**—Twelve cases of typhoid with two deaths have been reported from Edgewood, near Roanoke, as a result of using water from a contaminated spring.

**Personal**—Dr. Edwin L. McQuade, recently health officer of Albemarle County, has been appointed director of rural health work for the state department of health to succeed Dr. Irl C. Riggan, who was recently made state health officer.

## WEST VIRGINIA

**Toxoid Replaces Toxin-Antitoxin**—The West Virginia Department of Health announces that henceforth one-dose toxoid will be distributed for immunization against diphtheria instead of toxin-antitoxin. Physicians who still prefer the older preparation may have it on request.

**Society News**—Dr. Rome H. Walker and Mr. Joe W. Savage, Charleston, president-elect and executive secretary, West Virginia Medical Association, addressed the Greenbrier Valley Medical Society at Roncove, August 21, on medical economics. The Fayette County Medical Society was addressed at its meeting in Oak Hill, August 14, by Dr. Walter E. Vest, Huntington, on "Lung Abscess," and Dr. George E. Gwinn, Beckley, on "Newer Developments in the Treatment of Tuberculosis." At a meeting of the Logan County Medical Society in Logan, August 15, papers were presented by Drs. Oscar B. Biern and Richard B. Easley, Huntington, on "Medical Aspects of Cholecystitis and Cholelithiasis." Dr. Carl S. Bickel, Wheeling, discussed placenta praevia and toxemia of pregnancy before the Tyler-Wetzel Bi-County Medical Society at New Martinsville, recently. Dr. Waitman F. Zinn, Baltimore, addressed the Monongalia County Medical Society, Morgantown, August 7, on "Acute Infections of the Middle Ear and Its Complications."

## WISCONSIN

**Presentation of the Gold Seal**—At the annual dinner of the State Medical Society of Wisconsin in Green Bay, September 13, the gold seal of the society was presented to Dr. Arthur W. Rogers, Oconomowoc, president of the Waukesha County Medical Society and of the Milwaukee Academy of Medicine and formerly president of the state society, to Dr. Rock Sleyster, Wauwatosa, editor of the state society's journal, formerly president and secretary of the society, and now vice chairman of the Board of Trustees of the American Medical Association, and to Dr. Olin West, Chicago, Secretary and General Manager of the American Medical Association.

**Society News**—Dr. George H. Ewell, Madison, addressed the Columbia County Medical Society at the Wisconsin Dells, August 13, on "Diagnosis and Treatment of Diseases of the Rectum and Anus." At a meeting of the Polk County Medical Society, July 19, Drs. William T. Peyton, Minneapolis, and William A. O'Brien, St. Paul, discussed the diagnosis and treatment of malignant conditions and relationship of public health and the medical profession, respectively. Dr. Maynard H. Fuller, Green Bay, addressed the Shawano County Medical Society, July 26, on "Industrial Eye Injuries." Speakers before the Tenth Councilor District Medical Society at Iron River, August 15, included Dr. Myron O. Henry, Minneapolis, on "Supracondylar Fractures of the Humerus." Drs. Harold E. Marsh and Carl S. Harper, Madison, were guest speakers at a meeting of the Ninth Councilor District Medical Society at Marshfield, August 16, on "Treatment of Thrombophlebitis with Leeches" and "Toxemia of Pregnancy," respectively.

## WYOMING

**Rocky Mountain Spotted Fever**—Twenty-one deaths from Rocky Mountain spotted fever have occurred in a total of ninety-one cases reported for the year 1934 up to August 1, according to *Colorado Medicine*. It is pointed out that the northern two thirds of Wyoming produced all the cases, while the southern one third was entirely free. The wood ticks appeared earlier than usual this year and in greater numbers. The supply of the Spencer-Parker vaccine which is distributed free by the U S Public Health Service from Hamilton through the state health departments, was inadequate, this year less than half of the persons who wanted to be vaccinated could be accommodated.

## GENERAL

**Society News**—The Radiological Society of North America will hold its twentieth annual meeting at the Hotel Peabody, Memphis, Tenn., December 3-7. Further information may be obtained from the secretary, Dr Donald S Childs, 607 Medical Arts Building, Syracuse, N Y.

**Bequests and Donations**—The following bequests and donations have recently been announced:

St Vincent's Hospital New York \$65 000 by the will of the late Mrs Margaret Havens Hurlburt.

Mount Sinai and Beth Israel hospitals New York \$5 000 and \$2 500, respectively by the will of the late Harry M Goldberg. Each will also benefit from the residuary estate.

New Rochelle Hospital Association New Rochelle N Y \$10 000 by the will of the late Florence M Childs.

New Rochelle Hospital, \$1 000 by the will of George W Kuchler.

White Plains Hospital Association \$5 000 by the will of the late Clara B Brown.

**Officers of Academy of Ophthalmology and Otolaryngology**—Dr Frank E Burch, St Paul, was chosen president elect of the American Academy of Ophthalmology and Otolaryngology at the annual session in Chicago, September 10-14, and Dr Wells P Eagleton, Newark, N J, became president, other officers elected included Drs William Thornwall Davis, Washington, D C, Samuel Iglauer, Cincinnati, and Marie F Weymann, Los Angeles, all vice presidents, and William P Wherry, Omaha, secretary, reelected. The academy's medal of honor was awarded to Dr Carl Koller, New York, who first introduced cocaine as a local anesthetic fifty years ago. In the absence of Dr Koller, who was unable to attend because of illness, the medal was received by his daughter, Mrs James Becker, Highland Park, Ill.

**Mississippi Valley Tuberculosis Meeting**—The annual joint meeting of the Mississippi Valley Conference on Tuberculosis and the Mississippi Valley Sanatorium Association will be held in Cedar Rapids, Iowa, September 27-29, at the Hotel Montrose. In a symposium on the pathology of tuberculosis the following physicians will take part: Drs Frank P McNamara, Dubuque, Iowa, Charles A Doan, Columbus, Samuel A Levinson, Henry C Sweaney and Richard H Jaffe, Chicago, and Harold E Robertson, Rochester. Dr Henry Kennon Dunham, Cincinnati, will conduct an x-ray clinic Thursday evening, and among physicians who will deliver addresses are:

Dr Nathaniel G Alcock, Iowa City, Genito Urinary Tuberculosis.

Dr Michael H Ehert, Chicago, Clinical Types of Skin Tuberculosis and Their Biological Significance.

Dr Jacob J Wiener, Bedford Hills N Y, Status of the Tuberculous Patient Following Discharge from the Sanatorium with Medical Treatment Episodes and Collapse Therapy.

Dr Frederic Maurice McPhedran, Philadelphia, The X-Ray Film in Pulmonary Diagnoses—Standardization of Technique and Apparatus.

At the annual banquet Friday evening speakers will be Drs Walter L Bierring, Des Moines, President of the American Medical Association, and H Kennon Dunham, Cincinnati, president of the National Tuberculosis Association.

## Government Services

## U S Public Health Service

Passed Asst Surg Harold D Lyman relieved at Windsor Ont. Canada and assigned at the Relief Station Washington D C.

Passed Asst Surg Waldemar C J Dreesen relieved at Washington D C about September 15 and assigned at New Orleans (Algiers).

Passed Asst Surg Cassius J Van Slyke relieved at Chicago and assigned at Ellis Island.

Sr Surg Grover A Kempf relieved at Berlin Germany and assigned to Washington D C.

Surg Paul D Mossman relieved at Albuquerque N M and assigned at the marine hospital Ellis Island.

Surg Frank V Meriwether, relieved at New Orleans and assigned at the marine hospital Ellis Island.

Drs Frederick J Brady, and Thomas H Tomlinson Jr have been appointed and commissioned as assistant surgeons in the regular corps of the service.

## A Large City Without Fatal Automobile Accidents

While automobile traffic continues to take a terrible toll, which in spite of every effort of the authorities tends to increase, the shipping and industrial town of Sunderland, with a population approaching 200,000, is able to announce that it has no deaths from automobile traffic. This surprising result caused the minister of transport to inquire of the mayor the reason for the freedom of the town from fatal accidents. His answer shows that the reason can be given in one word—education. For a considerable time the police have given particular attention to traffic problems and in a tactful way have exercised a control that has had the effect of reducing unnecessary fast driving. Cautions, written and verbal, have been issued when necessary and only in serious cases, now reduced to a minimum, have proceedings against drivers been taken. By means of a local "safety week" the public has been made aware of the seriousness of the position as regards road accidents resulting from carelessness. Warning posters are displayed on boards made by members of the fire department. Transparencies bearing a warning are given to drivers and affixed to windshields and windows of all types of automobiles. The theaters show a slide two or three times daily bearing advice on the avoidance of accidents. Instruction in safety first principles is given in schools throughout the year. During three or four periods of the day the police assist across the street children going to and coming from school. This has a most beneficial effect in training the children to be careful in crossing the street. When the schools reassemble after the holidays, 20,000 warning leaflets will be distributed by the police to children between 6 and 13 years of age. The shop keepers and other residents of the town display warning posters issued by the National Safety First Association. It is to be noted that this praiseworthy effort has not produced any undue slowing or congestion of traffic.

## The Dangers of Sewers

From time to time fatalities occur among men working in sewers. Some of the larger authorities issue fairly comprehensive instructions for this work, but there is a want of uniformity. As no investigation had been made by any government department or advice issued, the Ministry of Health a year ago appointed a committee to inquire into the subject. In the report it is pointed out that the dangers to men entering sewers or sewage tanks are of two kinds: (1) flooding and (2) gases. As a precaution against the former, bars or chains should be provided at all manholes in sewers, so that they can be fixed across the sewer below the point at which the man is working. Gases are classified as asphyxiating, poisonous and inflammable. The composition of air in sewers usually differs little from that of the outside atmosphere, but it may be much modified by stagnation in the sewer, due to structural defects, or by the admission of gases or liquids which readily vaporize. When stagnation occurs, the solid matter undergoes fermentation and absorbs oxygen from air in the sewer. If there is little ventilation, the evolved gases gradually displace the air, so that the sewer atmosphere becomes irrespirable from reduction of its oxygen content. Of the gases that gain admittance to sewers, coal gas is the commonest, but acetylene, from decomposition of unspent calcium carbide, is occasionally found. Either may give rise to an explosive mixture. Of the vaporizable liquids that enter sewers, inflammable wastes from dry cleaning works are occasionally encountered, but gasoline is by far the com-

monest and may cause dangerous explosions. In sedimentation tanks the gases to be feared are usually those produced in the early stages of fermentation—carbon dioxide and hydrogen sulphide, but in septic tanks they are those produced in the later stages—methane and carbon dioxide. The dangers of asphyxiation from irrespirable gases can be removed only by adequate ventilation of sewers and tanks. The greatest risk in this country is that of poisoning by hydrogen sulphide. The first and principal precaution is to prevent accumulation of sewage or sludge by cleaning out tanks and, when necessary, sewers at frequent intervals.

It is laid down that with reasonable care accidents should not occur. The tests and precautions for ensuring safety are simple and should be strictly observed. Before any man enters a sewer or tank it should be ventilated. Tests must then be made for hydrogen sulphide (by exposing lead acetate paper for five minutes), for asphyxiating conditions (by a safety lamp) and for inflammable gases (by a detector lamp). All the men should be versed in the tests, and a life line should be worn by the first man entering a sewer or tank until safety has been established. So long as any man is in a sewer, three manholes (the one entered and that on each side) should be kept open and two men posted at the entry manhole. Smoking and the use of naked lights should be forbidden. Rescue kits should be carried by every sewer gang and kept apart from the ordinary tools, the man in charge of the gang being responsible. It should include at least two life lines and one breathing apparatus.

#### Public Health Service Under Indian Administration

That the cessation of British rule and the establishment of self government has disadvantages of which those who clamored for self government appear to have been oblivious can be illustrated in various parts of the world. In a letter to the *Times*, Mr C. L. Dunn, formerly a director of public health in the United Provinces, India, points out that, while there has been an increase in the number of hospitals and dispensaries since the health service was transferred to Indian Ministers in 1921, there has been a serious deterioration in the equipment of many hospitals and the qualifications for the personnel have been lowered. The United Provinces government reported on this deterioration in buildings and equipment to the Simon commission, and Mr Dunn vouches for a decline in the standards of cleanliness, discipline and efficiency generally, which has taken place in many hospitals in the United Provinces. In Assam they have been reduced in number and their qualifications lowered. In Bombay, Bihar and Bengal, though there has been an increase in the local staff, the provincial public health personnel, there has been a lowering of qualifications. In the Punjab the provision is so scanty that there is only one health officer and one sanitary inspector for approximately every million of the population, and in 1931 a committee of the provincial council recommended the abolition of the entire public health department. In the Central Provinces this has actually taken place. In Madras a great many of the so-called health officers have very low qualifications and some no special health qualifications at all.

In the engineering branch of the public health departments there has also been a setback. In 1921 each major province had a special branch of this kind, responsible for drainage, water supplies and other sanitary works and staffed by well qualified engineers. Progress in the introduction of drainage schemes, water supplies and other services was continuous. But since 1921 the great majority of qualified engineers doing this work have been dismissed and replaced by unqualified Indian operatives. As a result not only has progress stopped but many local bodies have failed to maintain existing drainage schemes and waterworks in repair. Waterworks are continually

breaking down, even in important cities and nuisances caused by defective drainage are almost unbelievable.

The main cause of all this deterioration is the maladministration of local authorities, to which convincing testimony is borne year after year in the reports of provincial governments. So little recognition is there of the value of efficiency that in one province the superintending engineer of the public health department was censured by the legislative council for reporting the facts, and the minister under whose authority the report was printed undertook that the officer should be asked to modify his report. Any good work that is being done, such as the inauguration of maternity and child welfare activities and missions to lepers, are due to voluntary agencies and receive little help from the governments.

#### Deafness Caused by Pneumatic Drills

The antinoise campaign has been described in previous letters. Local authorities in London are considering the adoption of silencers for pneumatic road-braking machines on account of the protests made by hospitals and the public in residential areas. A pneumatic drill probably creates more noise than any other device used in the streets of London, and experiments have been in progress for some time to mitigate the nuisance. Silencers have been brought to the notice of the local authorities and in some cases taken up by them. But the contractors object to their use because of a small loss of efficiency. It has been found that about three fourths of the noise produced is due to the "bark" of the exhaust air after compression, and all attempts to muffle it produced prohibitive back pressure in the drill, with consequent loss of power. The latest type of silencer is claimed to lessen the noise of escaping air by 60 or 70 per cent, with a loss of well under one tenth in efficiency. Apart from the effect on the nerves of the public, the noise of the unsilenced drills in time produces partial deafness in nearly all those who work them.

#### Research on the Storage of Food

The progress made by research on the transport and storage of fish, fruit and vegetables is shown in the annual report of the Food Investigation Board, which has just been issued. The work was undertaken with the object of improving the food supply of Great Britain. It was found that fish can be kept in good condition aboard a trawler in crushed ice for as long as ten or twelve days. For trawlers that make trips involving long absence from port, the exact conditions for brine freezing and cold storage of the common sorts of white fish were worked out. Work has been done on the herring with the aim of improving the smoking of this fish by defining the conditions required for producing kippered herrings of high quality. It was found that if herrings are rapidly frozen in brine and stored at a low temperature they will retain their quality for a considerable period. Kippers made from them after four months' storage are barely distinguishable from those made from the freshest fish.

#### CHILLED MEAT

The trade in frozen mutton and lamb has been thoroughly investigated in cooperation with various interests in New Zealand and Australia. The most important advance as regards beef was the demonstration on a semicommercial scale by the Low Temperature Research Station that it can be held in perfect condition in a chilled state for as long as sixty or seventy days in an atmosphere containing from 10 to 20 per cent of carbon dioxide. Provided the necessary gas tightness can be secured in the refrigerated spaces of ships, Australia and New Zealand can send their beef to the United Kingdom in chill. Recently the Low Temperature Station showed that bacon and pork can be stored successfully for considerable periods in high concentrations of carbon dioxide. This is

important, as bacon cannot be stored successfully for any length of time merely by the use of cold, and consequently it has not been feasible to import it from Australia and New Zealand.

#### GAS STORAGE OF FRUIT

Much of the board's work, especially on fruit, cannot find its full application unless it is accompanied by parallel work overseas. Successful cold storage of fresh fruits depends on a number of factors. Different varieties do best at different temperatures. The work on the gas storage of fruits is of more value to the home than to the overseas producer. Remarkable individuality was found in the response of different varieties of English apples to atmospheres containing different proportions of oxygen and carbon dioxide. In the present state of knowledge it is impossible to foretell how a particular fruit or a particular variety of fruit will respond to an abnormal atmosphere of given composition. It is thus essential to ascertain by trial the exact requirements of the fruit in question. But the general principle of gas storage has been shown to be beyond dispute though its possibilities as an alternative to cold storage are largely unexplored.

#### British Medical Association to Meet in Australia

The 103d annual meeting of the British Medical Association will be held in Melbourne next year during the week beginning September 9, under the presidency of Sir Richard Stawell, consulting physician to the Melbourne Hospital and to the Children's Hospital, Melbourne. The work of the meeting will be divided into fourteen sections, and it is noteworthy that the presidents of these are in all cases drawn from Great Britain. Lord Horder, medicine, Sir Thomas Dunhill, surgery, J. S. Fairbairn, obstetrics and gynecology, A. E. Barclay, radiology and radiotherapeutics, Robert Hutchison, diseases of children, Prof. Edwin Bramwell, neurology and psychologic medicine, Prof. E. W. Hey Groves, orthopedics, F. F. Muecke, otorhinolaryngology, Prof. A. Murray Drennan, pathology and bacteriology, Sir H. J. Gauvain, public medicine, including tuberculosis, industrial and tropical hygiene, and the history of the development of medicine in Australia, J. M. H. Macleod, dermatology, E. K. Le Fleming, medical sociology, A. J. Ballantyne, ophthalmology, and Sir William Willcox, pharmacology, therapeutics and anesthesia.

#### The International Congress of Neurologists

The fourteenth International Congress of Neurologists was held in the Salpêtrière Hospital, in the amphitheater in which Charcot taught. Dr. Vurpas delivered the opening address, on "The Method to Follow in the Observation and Coordination of the Neurologic Facts." The question discussed was "Study on the Vegetative Centers in the Mesencephalon." Mr. Laruelle of Brussels presented a paper on the anatomy of the median diencephalon and of the upper centers of the region that forms the wall of the third ventricle, and discussed the various cell types, the topography of the nuclei, and the question of vegetative localization. He opposes the view of Karplus and Kreidl and holds that the vegetative centers are not restricted to the diencephalon but extend upward toward the cortex.

J. Lhermitte discussed the role of the hypophysis and the anatomoclinical syndromes ascribable to the hypothalamic vegetative apparatus. He suspects the existence in the hypothalamus of a double polarity, one of a nervous order and the other of a hormone nature. Thus one can differentiate, on the one hand, the syndromes of hypophyseal origin (acromegaly, gigantism, Cushing's disease, Simmonds' disease or hypophyseal cachexia), and on the other hand syndromes involving the tuber cine-

reum and the infundibulum: diabetes insipidus, narcolepsy, obesity and lipodystrophies, adiposogenital syndrome, premature sexual development, and the like. He discussed the possible relations between the genital glands and the hypothalamus in hematopoiesis and considered the relations between the hypothalamus and epilepsy, and its influence in certain mental disorders. Passing over such vegetative disorders as salivary, sudoral, lacrimal and sebaceous hypercrimias, arterial hypertension and peptic ulcers, he emphasized merely from what angles study of these questions should be pursued. Physiologic specificity of the centers revealed by histology in the diencephalon, nature of the lesions provocative of the syndromes observed, and their grouping under general syndromes. Many members of the assembly (Nicolesco, Marmesco, Façon, Bruch, Andre Thomas, de Martel, Ayala and others) reported observations of cases illustrating the pathology of the hypothalamus. Andre Thomas contributed a paper on thermic regulation and the part played therein by the region of the infundibulum and the tuber cinereum, basing his contentions on experimental tests and on numerous anatomic observations. Cerebral tumors, for example, may be revealed by certain febrile disorders. But the tumors are not always localized in the region of the infundibulum and the tuber cinereum. Surgical hyperthermia appears associated particularly with disequilibrium of intraventricular pressure and possibly with a reaction of the choroid plexuses. In epidemic encephalitis thermic disorders exist, and their lesions are distributed, by a process of selection, throughout the diencephalon and the mesencephalon. In fact (according to Thomas), one cannot define the role of the region of the tuber cinereum and the infundibulum toward thermoregulation or fever without including many other regions of the neuraxis that cooperate with it. If the tuber cinereum exerts a preponderant influence such that it can be accorded the significance of a brain center, it must be recalled that more or less remote lesions may modify the thermic curve, either by acting at a distance on the infundibulum or by some other mechanism. Aside from experimental research, one must recognize that most observations based on pathology supply arguments of probability rather than of certainty in favor of a center in the tuber cinereum or the hypothalamus.

#### French Assembly of General Medicine

The twelfth session of the French Assembly of General Medicine was devoted to a study of the dietary habits of certain regions with relation to the public health. The communications furnished by the physicians of the provinces constitute a remarkable survey of the various types of alimentation, from which results the local predominance of various types of diseases of the digestive tracts and of organic disorders. For example, gout and urinary lithiasis are unknown in the peasants who drink only cider. On the other hand, the latter are more exposed to poor dentition and to gastric ulcer that may lead to cancer. The war served to increase in the rural districts the consumption of meat, to which the peasants became accustomed during their service in the army. The conclusions that summarize the discussions and that were unanimously accepted by the assembly were the following: The diet of the French people is usually ample. An inadequate diet is found chiefly in hovels but also among the well-to-do classes through ignorance of what constitutes a suitable diet, and, particularly among the women owing to the fear of losing their slender figures. Physical education and sports, which are increasingly favored, have a tendency to establish a more rational diet. Alcoholism is less frequent among the younger generation, which is disciplined by athletics and the various sports. Hygiene has left its marks on puericulture. Cholera infantum has become a rarity and has ceased to be the social scourge it was a number of years ago. In the remote rural districts this result

appears to be due to the action and instruction of the family physician. The assembly called to the government's attention four points that are important: 1 The bread is frequently of poor quality and poorly baked. There is unanimous opposition to bread containing chemical products. 2 The supervision of milk is inadequate. Milk from poorly nourished and unhealthy cows should be rejected. 3 Rural school children are often puny because they lack suitable lunches and are reduced to one warm meal a day, and that in the evening. 4 Physicians demand that the government supervision, which has proved effective for oysters, be extended to other types of shellfish and that the raising of bivalves in waters into which sewers empty shall be prohibited.

#### Monument to Dr Roux

The monument erected to the memory of Dr Roux in the gardens of the Hôpital des enfants-malades was dedicated recently in connection with the holding of the international congress of French speaking pediatricians in Paris. The monument consists of a large low relief, the work of the sculptor Rouché, which represents the eminent scientist in his laboratory examining a microscopic specimen. At the dedicatory ceremonies Dr Martin, who was the collaborator of Roux at the Institut Pasteur in his discoveries of antidiphtheritic serotherapy, gave a biographic sketch of the scientist, interspersed with personal reminiscences, while Professor Marfan emphasized the importance of this discovery. The ceremonies were attended by many official delegates.

#### Hereditary Cutaneous Diseases and Consent to Marriage

In an address before the medical society of Frankfurt-on-Main, Schmidt-La Baume warned against exaggeration in the medical consultations on marriage. Only a small number of hereditary diseases are of practical importance. In research on these diseases, race, family and twin relationships constitute excellent research material. In studying familial pathology, great caution must be exercised, as some diseases must have left traces in almost every family tree. A common source of error is the inaccuracy of statements with regard to family trees. One must distinguish carefully between medical diagnoses and statements derived from the family history. If a certain disease is dominant, it is more important to study complete groups of siblings than to search through a large number of generations. Many siblings, however, do not attain the age in which the disease appears. It will be understood that recessive diseases are not recognized until late as hereditary diseases. A denial, by the consultant, of approval of a contemplated marriage should be based only on absolutely certain results of hereditary research.

The attempts to build up a rigid system characterizing the various hereditary diseases are still rudimentary. Among the large number of cutaneous diseases many eliminate themselves, many others are rare and many are not so important, as the damage they cause is slight. For example, the presumably dominant varices are not sufficient reason for withholding consent to marriage. Of importance are chiefly bullous conditions, keratoses and blastomas. Of the bullous conditions especially epidermolysis dystrophica and epidermolysis simplex deserve attention. Hereditary transmission in the latter case being dominant and in the former recessive. If the family history of a candidate for marriage shows these diseases the medical consultant may with justice advise caution or actually prohibit marriage. According to the literature pemphigus vulgaris is hereditary but since it will be impossible to find a family tree

that furnishes unequivocal proof of this contention, it is not a valid reason for refusing consent to a marriage. In the case of light dermatoses, hereditary influences have been demonstrated with certainty, hence consent to marriage should under all circumstances be withheld. Folliculoses and hidroses have only a cosmetic interest, it should, however, be emphasized that acne vulgaris is of a highly hereditary nature. Ichthyosis congenita is of a recessive hereditary nature, the new-born with this disorder usually die from its effects. Keratoma palmare, which renders patients incapable of doing any form of manual work, is of a pronounced hereditary type. Xeroderma pigmentosum is a severe type of disease that usually leads to the formation of malignant tumors, marriages between persons with too high a degree of consanguinity are frequently associated with this condition. In the family trees one finds a morbidity of 25 per cent, there is evidence therefore of a typically recessive disease. In the three last named diseases, permission to marry should be refused under all circumstances. Of the anomalies affecting the males, onychogryposis and anonychia are of a dominant hereditary nature, but these conditions do not assume an important role in connection with consultations on marriage.

Malignant tumors are by no means uniform in their hereditary aspects. Recklinghausen's disease is sometimes dominant but not regularly so, sterilization is demanded in some quarters. Psoriasis, or at least the predisposition to it, is of a dominant hereditary nature, however, in only one case out of seven does the person thus menaced develop the disease. There is no adequate reason to warn a person thus menaced against marriage. Infectious dermatoses are not of practical importance in this connection. An urgent warning is uttered against exaggerations with reference to cutaneous disorders in connection with heredity and great caution should be observed in the matter of withholding consent to marriage.

As far back as the closing years of the last century, an international congress in Paris demanded prohibition of marriage in the presence of venereal disease. The consultation centers for venereal patients are not much frequented. The crusade against venereal disease must be carried on in an entirely different manner than in the past. The preliminary instruction should be given in the upper classes of the common schools. In contradistinction to gonorrhea, syphilis is exceedingly important for posterity. If syphilis is treated in the primary stage, a negative serologic test must be demanded over a period of two years. But if syphilis is not treated until the secondary stage is reached, not only the serum test but also examination of the cerebrospinal fluid must be negative for at least five years before consent to marriage can be given. In connection with the examination, it must be borne in mind that malaria may induce a positive Wassermann reaction. In the case of congenital syphilis, this test cannot be influenced by treatment but sometimes becomes negative spontaneously after a period of years. In the presence of neurosyphilis and/or a visceral involvement, marriage must be prohibited under all circumstances, the candidates for marriage being informed of the exact situation. The greatest caution should be used toward all new antisyphilitic remedies for the complete testing of their efficacy must be extended over generations. Until such extensive research has been completed there is no question of a serious competitor of arsphenamine. It cannot be too strongly emphasized that a person with syphilis is an absolutely unsuitable partner for marriage.

#### Moral Offenses During the Postwar Period

According to extensive research by Dr Julier, the number of offenses against good morals recorded for 1913 (18,862 cases) has not been equaled in any year (up to 1930) since the war. In 1926 the total was 16,441, following which a retrogression

set in, the total number for 1930 having been 13,630. The first year after the war (1919), a marked reduction in the total number of recorded offenses is observable, but the reduction is due to postwar laxness in following up cases and hence permits no conclusions with reference to real conditions. The figures for incest reached the peak for the prewar period in 1913, from 1919 on they showed a gradual increase and reached their postwar peak in 1925. The underlying cause cannot be unemployment, for this crime shows a high incidence also in the rural districts. Incest with violence applied to children shows an almost uninterrupted increase, with its peak in 1926, and continues then along about the same level, which corresponds to the prewar figures. Exhibitionism reached its peak in 1926, which was followed by a considerable decline. Homosexual crimes of men increased markedly between 1921 and 1924 and then declined. On the other hand, the increase of cases of abuse of authority by guardians, private educators and others is due mainly to ethical deterioration following a period of reduced sense of moral responsibility. In 1930 there were recorded 244 such cases, as against 130 in 1913. As to the participation of juveniles themselves in such crimes, incest accompanied by violence exceeds among male juveniles all other punishable offenses in frequency and, in particular, far exceeds the incidence of criminal moral offenses among female juveniles. In these statistics, however, it must be borne in mind that official statistics comprise only cases in which a sentence was imposed by the court of first instance, so that the numerous offenses committed by unknown persons, the acquittals, the withdrawals of charges, and cases in which secrecy was observed for moral reasons, are not included.

#### Reorganization of the Public Health Service

In the reorganization of the public health service, which has frequently been discussed in these letters, the federal government has adopted new measures. In the past, in the various *lander* of the German reich the administration of the public health service was in the hands of government health officers, which were linked up with the lower administrative bodies. In view of their multiplicity of tasks, the health officers were unable to satisfy the constantly increasing demands particularly as regards the providing of financial aid for those in need of welfare care and treatment, so that the communes turned over to their own communal physicians the task of securing financial aid and treatment for the needy, and also the officers of the social insurance system and of the organizations for the care of war victims began to appoint their own confidential physicians. Other centers, then recognizing the importance of health values for the people, began to be active in this field. But the fact cannot be ignored that these tasks require a uniform administration. The law that goes into effect, April 1, 1935, furnishes the basis for such reorganization. This law provides that, for the uniform administration of the public health service in the cities and rural districts, bureaus of health shall be created and directed by government health officers. The duties of these bureaus are (1) execution of the medical tasks of the sanitary police, administration of hereditary and racial matters, including consultations on marriage, enlightenment of the people in hygienic subjects, care of the health of school children, consultation services for mother and child, welfare aid for the tuberculous, for venereal patients, for persons with physical handicaps, for invalids and for drug addicts, (2) medical cooperation in measures for the promotion of proper care of the body, including physical exercise, and (3) the activities of the health bureaus, the courts and the confidential physicians, so far as they are entrusted to the health officers. In addition, further duties of the character of those of confidential physicians may be assumed in the field of social insurance, that is, in the *krankenkassen* and the like.

The hospitals, the sanatoriums and the convalescents' homes, on the other hand, are to remain under the same administration as before. These bureaus of health are government institutions, toward the support of which the cities and the rural districts will contribute. In some instances, existing institutions of the cities and rural districts will be allowed to take over the functions of the newly created bureaus of health, in which event the central government will contribute to their financial upkeep, since, in general, the reich contributes to the support of the public health service. The bureaus of health are also empowered to charge fees, in accordance with a fee schedule to be established by the federal minister of the interior. In short, this new law will effect a uniform reorganization of the public health system under the direction and general supervision of the federal minister of the interior.

#### Celebration of the Professorship of Emile de Grosz

Dr Emile de Grosz, professor of ophthalmology at the University of Budapest, president of the International Trachoma Committee and leader of the Budapest postgraduate medical courses, solemnized the thirty year jubilee of his professorship. Since January 1904 he has been head of the Budapest eye clinic. For this occasion his pupils edited a souvenir volume. During these thirty years, 659,068 outpatients have attended his clinic, while the number of inpatients amounted to 52,032.

The ruling principle at his clinic is the motto of his predecessor, the celebrated clinician Arlt: "*Salus aegroti suprema lex esto*." In his clinic the welfare of the patient is supreme, and the didactic feature is secondary. The main requirement of practical medical teaching is that the behavior of the teacher with the patients should serve as an example to the students.

During the thirty years, 4,326 glaucoma patients were admitted to the hospital and more than 10,000 glaucomatous outpatients were attended at the clinic. Of the patients admitted to the hospital, 18.6 per cent had no light sensation at all, and the rate is still higher among the outpatients.

In the development of his clinic, Professor Grosz has paid particular attention to the development of a library. The grant for this purpose from the ministry was inadequate, and Grosz had to look for another source of money to be able to augment the library. Eventually this was found in fees paid to him by the so-called extra patients attending the clinic. In the jubilee booklet, Professor Grosz complains of the high prices of books and periodicals, rendering difficult their purchase. He mentions one book, the "*Kurzes Handbuch*," each volume of which costs 185 marks, the whole work of seven volumes 1,780 pengos (about \$510), for which sum quite a nice little house can be purchased in one of the suburbs of Budapest. The subscription to German ophthalmologic periodicals varies between 60 and 120 marks.

The clinic has a complete library of rare books on the work of ophthalmologists. Most precious among them are Jacob Schalling's "*Ophthalmia sive disquisitio hermetico-gallenica de natura oculorum*," which appeared in German and Latin in 1615 in Erfurt. Georg Bartsch's "*Augendienst*," published in Dresden in 1583 which, as the first ophthalmologic manual, reached three editions and a valuable book Vopiscus Fortunatus Plempius's "*Ophthalmographia sive tractatus de oculo*," the first edition of which appeared in 1632 in Amsterdam. A curious book is that written by Laurentius Heister, professor of surgery and anatomy at the University of Altdorf, "*Apologia de cataracta glaucomate contra Wolhusii*" (1717). This book was written by Heister in defense of his earlier published book against Woolhouse, a contemporary English physician.

De Grosz's eye clinic is equipped with a modern bacteriologic and serologic laboratory, a pathologic-histologic section that attracts many distinguished foreign guests. During the course of last year prolonged studies in the latter laboratory were made by O Schlopf of Tübingen and S R Gifford and T D Allen of Chicago. During the course of the past thirty years more than 300 publications of pathologic reference appeared, mainly in foreign medical journals, written by the staff of de Grosz's clinic. An integral part of the clinic is the optical laboratory, which is a museum of optical instruments. All scientific optical instruments can be found here. The teaching staff of de Grosz's clinic consists of one adjunct, three assistants, three salaried juniors, three unsalaried assistants and five unsalaried juniors. The number of students who attended Professor de Grosz's lectures during the thirty years was 8,763. The attendance was greatest in the second session of the 1918-1919 school year, 708, and the smallest, 117, in 1928-1929.

Aug 30, 1934

### Celebration of the Fourth Centenary of the Discovery of Canada

To add to the ceremonies organized by the Canadian government for the celebration of the fourth centenary of the discovery of Canada by Jacques Cartier, the thirteenth Congress of French-Speaking Physicians of North America held a joint session with the twenty-third annual Congress of the French-Speaking Physicians of Europe, which convenes alternately at Paris and in some large city of Belgium or Switzerland. The joint congress was attended by 143 French physicians, five of them professors at the Faculté de médecine de Paris, under the conduct of Prof Emile Sergent and Prof Henri Hartmann, several professors from Lyons, Bordeaux and Marseilles, a number of physicians and surgeons from the hospitals of Paris and the provinces, and a group of Belgian and Swiss physicians. Likewise a number of physicians from the United States, including Prof Max Einhorn of New York, were in attendance. The chief topics considered were "Pancreatitis," "Hypoglycemic States" and "Pyretotherapy." On the opening topic (pancreatitis) papers were presented by Albert and Jean Lesage of Quebec, Professors Cade and Ravault of Lyons, and Rambeaud and Albert Puech of Montpellier. P Brocq, surgeon to the "hopitaux de Paris," and Professor Berard of Lyons gave an account of their studies on the surgical treatment. It appears that pancreatitis, in the first stage of edema, sometimes clears up spontaneously. Einhorn shared that view and reported successful results obtained with duodenal intubation. Brocq questioned these results, however, and expressed his doubts as to whether a true case of pancreatitis was involved. On the second topic (hypoglycemic states), Prof Marcel Labbe of Paris, Dr Jean La Barre of Brussels and Professors Lemieux and S Leblond of Ghent furnished three papers describing the role played by the various endocrine glands. The third topic (pyretotherapy) was considered by Charles Richet Jr of Paris, Henri Roger of Marseilles, and Fribourg-Blanc, A Halphen and Jacques Auclair of Paris, the last two speakers dealing chiefly with the use of short waves and diathermy. The diseases in which pyretotherapy has been tried during recent years were reviewed, including dementia paralytica, septicemia, gout and diabetes. The speakers emphasized that the results of pyretotherapy are rather uncertain being sometimes most remarkable and sometimes temporary or even almost nil, without any assignable reason to explain the widely different therapeutic effects. The subject is still controversial, and extended experimentation will be necessary to clarify the situation. The numerous unofficial communications dealt with widely different subjects, as is usual. International congresses with too exten-

sive programs are like vast expositions to which every one brings his product and at which attention is generally dissipated. They are clearing houses for medical ideas. To get the full value of attendance at such a congress, a report of the proceedings should be read later. The sessions, which lasted four days, were held simultaneously in two different auditoriums. In addition, every morning, in five hospitals, lectures were delivered by eminent foreign specialists, French or Belgian. Particular attention may be called to the lectures of Prof Pierre Duval on "Postoperative Azotemia," of Professor Hartmann on "Stenosing Rectitis," of Professor Fiessinger on "Les gros foies de surcharge," of Professor Sergent on "The Results of Thoracoplasty and of Phrenicectomy," of Dr Oscar Mercier on "The Diseases of the Neck of the Bladder," and of J N Lavergne on "The Diagnosis of Hydronephrosis."

Emphasis was laid on research on tuberculosis. Professor Arlong of Lyons presented a study on the avian bacillus and the tuberculous virus, while Dr Edouard Morin offered a paper on the same subject. A special section was devoted to mental hygiene and to psychiatry, to which the Canadian physicians made important contributions. The congress, which was presided over by Prof Albert Paquet of Quebec, was the occasion for many social functions. On the opening day the foreign conventionists proceeded to the cemetery for the purpose of depositing floral wreaths on the tomb of Prof Arthur Rousseau, who had been chosen to preside at the congress but who died several months ago. A eulogy in his memory was delivered by Prof Emile Sergent.

## Marriages

MALVERN BRYAN CLOPTON, St Louis, to Mrs Rachel Lowe Lambert of Princeton, N J, in Rindge, N H, July 10

JOHN SASSER MCKEE JR, Morgantown, N C, to Miss Betty Ambler McGill of Appomattox, Va., June 30

JOHN RICHARD SHANNON MAYS, Macon, Ga, to Miss Geraldine Barrett of Hendersonville, N C, June 2

ANDREW MUNCY GROSECLOSE, Roanoke, Va, to Miss Mary Katherine McLaughlin of Richmond, July 5

HERBERT STEPHAN DIECKMAN, Evansville, Ind, to Miss Ona Emily Boyd of Indianapolis, May 24

HENRY SOFOROUS BOURLAND, Drexel Hill, Pa, to Miss Inez Reeves at Bradford, Iowa, June 22

HENRY PERRINE COLMORE, San Juan, P R, to Miss Mary Virginia Thomas of New York, June 23

FRED GLENN DE BUSK, San Francisco to Miss Maurine A Jenkins of St Paris, Ohio, June 17

THOMAS CYPRIAN LAWFORD to Miss Doris Louise Petty, both of Hilton Village, Va, July 7

JOHN MARSHALL WINKFIELD, Strasburg, Va, to Miss Mary G Boland of Reading, Pa, July 2

CHARLIE FRANK MANGES to Mrs Susie Robinson Ware, both of Blacksburg, Va, July 2

MATTHEW J BOLAND, Hamburg, Pa, to Miss Eleanor Mundy of Tamaqua, May 31

ORVILLE LINDSAY ABBOTT, Bellflower, Ill, to Miss Truth Kirk at Bloomington, June 16

ARTHUR WILLIAM ABTS to Miss Frances Reinhart, both of Humphreys, Neb, June 15

GALITAN NEWTON WILSON to Mrs Louise Amiot, both of Vernon, Texas, June 16

WILLIAM DEVITT, Allenwood, Pa, to Miss Lida Wendle of Lewisburg recently

HUGO ALFRED AULER to Miss Mary Blanton, both of Austin, Texas, June 12

VIRGIL C DAVES, Vienna, Ga, to Miss Henrilea Gross of Alamo, June 3

MARK DANIEL to Miss Evelyn Lipkin, both of New York, recently

## Deaths

**William Campbell Posey** ☉ Radnor, Pa., University of Pennsylvania School of Medicine, Philadelphia, 1889, Chairman of the Section on Ophthalmology of the American Medical Association, 1909-1910, and at one time member of the Advisory Committee on Trachoma Among the Indians, member of the American Academy of Ophthalmology and Otolaryngology, member and past president of the American Ophthalmological Society, fellow of the American College of Surgeons, since 1922 member of the board of directors of the National Society for the Prevention of Blindness, formerly professor of diseases of the eye, Philadelphia Polyclinic for many years on the staffs of the Wills Hospital, Howard Hospital, Children's Hospital and the Chestnut Hill Hospital, Philadelphia Abington (Pa.) Memorial Hospital and the Westerly (R. I.) Hospital, co-author of "Treatise on Diseases of the Eye, Ear, Nose and Throat," "The Eye and the Nervous System" and "The Wills Hospital of Philadelphia", author of "Hygiene of the Eye", aged 68, died suddenly, September 5 of cerebral hemorrhage while aboard the liner *Rer* en route to the United States from Naples, Italy

**William Cline Borden** ☉ Lieut. Colonel, U. S. Army, retired Washington, D. C., Columbian University Medical Department, Washington, 1883, entered the army as an assistant surgeon in 1883, veteran of the Spanish-American War was promoted through the various grades to that of lieutenant colonel in 1909 when he retired for disability in line of duty returned to active service during the World War as chief of the surgical service, Walter Reed General Hospital, 1917-1919 member of the House of Delegates of the American Medical Association in 1904, professor emeritus of surgery, formerly dean, professor of surgery, medical ethics and histology, George Washington University School of Medicine, professor of military surgery, Army Medical School, and professor of surgical pathology and military surgery, Georgetown University School of Medicine, 1898-1907, a founder and fellow of the American College of Surgeons, surgeon in chief at the George Washington University Hospital, 1909-1931, aged 76, died, August 18, at his summer home in Chaumont, N. Y.

**Maurice Fishberg** ☉ New York, New York University Medical College 1897, clinical professor of medicine, University and Bellevue Hospital Medical College, 1915-1928, vice president of the New York Academy of Sciences, 1909-1910, consultant to the Montefiore Hospital County Sanatorium, Bedford Hills, N. Y., author of "Materials for the Physical Anthropology of the Jews," "The Jews—A Study of Race and Environment," and "A Treatise on Pulmonary Tuberculosis", aged 62, died suddenly, August 30, of heart disease

**Hugh Wilkinson** ☉ Kansas City, Kan., Rush Medical College, Chicago, 1901, past president of the Wyandotte County Medical Society, secretary of the Kansas City Southwest Clinical Society, fellow of the American College of Surgeons, served during the World War, surgeon to the Bethany Methodist Hospital, on the courtesy staff of St. Margaret's and the Providence hospitals, aged 57, died, August 14, of coronary thrombosis

**Joseph Baxter Emerson**, New York, University of Virginia Department of Medicine, Charlottesville, 1876, member of the Medical Society of the State of New York and the American Otolaryngological Society, for many years on the staffs of the Englewood (N. J.) Hospital and the Manhattan Eye and Ear Hospital, aged 80, died, July 24, at the home of his daughter near Charlottesville, Va., of carcinoma

**Carl Ferdinand Bookwalter** ☉ Chicago, Johns Hopkins University School of Medicine, Baltimore, 1910, assistant professor of otolaryngology, Northwestern University Medical School, fellow of the American College of Surgeons, on the staff of the Passavant Memorial Hospital, aged 54, was found dead, September 10, in a hotel at Danville, Ill., of a gunshot wound, presumably self-inflicted

**Paul Edward Allen**, Cherokee, Iowa, State University of Iowa College of Homeopathic Medicine, Iowa City 1910, member of the Iowa State Medical Society, past president of the Cherokee County Medical Society, on the staff of the Sioux Valley Hospital, aged 51, died, July 2, of streptococcal infection

**Benjamin Alexander Owen** ☉ Perry, Okla., Maryland Medical College, Baltimore, 1905, also a pharmacist, past president and secretary of the Noble County Medical Society, county superintendent of public health, aged 59, died, July 17, in the Enid (Okla.) Hospital of carcinoma of the pancreas

**Shirley Dan Folsom**, Muscatine, Iowa, Hahnemann Medical College and Hospital, Chicago, 1917, member of the Iowa State Medical Society, served during the World War, on the staff of the Benjamin Hershey Memorial Hospital, aged 47, died suddenly, July 22, of acute dilatation of the heart

**Philip Charles Douress**, Trenton, N. J., Jefferson Medical College of Philadelphia, 1912, member of the Medical Society of New Jersey, served during the World War, police surgeon, on the dispensary staff of St. Francis Hospital, aged 46, was killed, August 30, in an automobile accident

**Charles Ernest Howard**, Cogswell, N. D., American College of Medicine and Surgery, Chicago, 1905, served during the World War, aged 54, died, July 29, in the Veterans Administration Facility, Fargo, of chronic nephritis, cirrhosis of the liver and Korsakoff's syndrome

**Charles Hunter Drake**, Birmingham, Ala., Tulane University of Louisiana Medical Department, New Orleans, 1906, member of the Medical Association of the State of Alabama, served during the World War, aged 57, died, August 14, of chronic hypertension and hemiplegia

**Floyd McKennan Baldwin**, South Pasadena, Calif., Rush Medical College, Chicago, 1903, served during the World War, formerly operated a hospital bearing his name in Redfield S. D., aged 58, died, August 16, in the Palo Alto (Calif.) Hospital, of cerebral hemorrhage

**Henry Graham Bartlett**, Benton Harbor, Mich., Chicago Homeopathic Medical College 1896, member of the Michigan State Medical Society, formerly health officer of St. Joseph, aged 64, died August 21, of cerebral hemorrhage and mitral insufficiency

**George Curtis Ellis**, Chicago, Rush Medical College, Chicago, 1918, on the staff of the Provident Hospital, aged 44, died September 2, in the Albert Merritt Billings Hospital, of carcinoma of the rectum with metastasis to the liver

**Max Green**, Philadelphia, Jefferson Medical College of Philadelphia, 1903, member of the Medical Society of the State of Pennsylvania, on the staff of the Mount Sinai Hospital, aged 64, died, August 19, of heart disease

**Leon Deville**, San Diego, Calif., College of Physicians and Surgeons, medical department of the University of Southern California, Los Angeles 1911, aged 60, died, June 7, of acute myeloid leukemia and bronchopneumonia

**Philip Benjamin Fry** ☉ Benicia, Calif., College of Physicians and Surgeons of San Francisco, 1902, past president of the Solano County Medical Society, aged 62, died, August 21, of fatty degeneration of the heart

**Frank Hinchey**, St. Louis, Missouri Medical College, St. Louis, 1894, member of the Missouri State Medical Association, on the staff of the Missouri Baptist Hospital, aged 66, died August 9, of heart disease

**William H. Wilson**, Washington, D. C., Howard University College of Medicine, Washington, 1907, clinical instructor in surgery at his alma mater, on the staff of Freedmen's Hospital, aged 51, died, June 27

**John Brockinton Pressley**, Santa Rosa, Calif., University of California Medical Department, San Francisco, 1882, aged 74, died, June 22, in the Santa Rosa Hospital, of chronic endocarditis and myocarditis

**Robert H. Harrison**, Houston, Texas, Medical College of Ohio, Cincinnati, 1883, aged 73, examining surgeon to the Southern Pacific Hospital, where he died, July 14, of myocarditis and angina pectoris

**Charles Stuart Hutchison**, Los Angeles, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898, aged 60, died suddenly, August 4, of cerebral hemorrhage

**William H. Harris**, Augusta, Maine, University of Vermont College of Medicine, Burlington 1888, member of the Maine Medical Association, aged 72, died, June 13, of arterio sclerosis and nephritis

**Churchill Charles Franklin** ☉ Trenton, N. J., Harvard University Medical School, Boston, 1925, aged 37, died, July 25, in St. Francis Hospital, of tuberculous arthritis and pulmonary tuberculosis

**Henry Sumner French**, St. Paul, University of Minnesota Medical School, Minneapolis, 1920, aged 41, died, August 2, in the Ancker Hospital, of injuries received when struck by an automobile

**Joseph Schofield Winters**, Bessemer, Ala., Louisville (Ky.) Medical College, 1890, member of the Medical Association of the State of Alabama, aged 67, died, August 5, of cerebral hemorrhage

## Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted, on request.

### TUBERCULIN TESTING AND INCIDENCE OF TUBERCULOSIS

To the Editor—I have read with some interest your article on tuberculin testing which appeared in *Queries and Minor Notes* in *The Journal* May 26 and I feel that your comments are not sufficiently comprehensive. You have presented but one phase of a highly controversial subject and that giving the view of what is probably a minority of those interested in this work.

All will agree that a person who reacts to tuberculin has been exposed to tubercle bacilli but I question strongly that seeking this source often results in finding an open case of tuberculosis unless the reactor happens to be an infant or very young child in which case owing to the limited number of people with whom he comes in contact it is frequently possible to determine such a source. But as the child grows older and his circulation among the population becomes wider, the possibility of detecting such a source becomes remote and in the case of adolescents and adults the task assumes such proportions as to require a spirit of investigation and a corps of searchers such as few could possibly possess.

Even when a definite tuberculous lesion is demonstrable in the child it is no simple matter to find the original source of infection at home. In a recent article Edwards (*Am. Rev. Tuberc.* 27:611 [June] 1933) states that in the examination of the families of a large number of children who have been diagnosed as having tuberculosis of childhood only a single case of adult pulmonary tuberculosis could be found.

It is true that the positive test establishes the fact that the tissues are sensitive or allergic to the products of growth of tubercle bacilli, but it is by no means so certain as is implied that such people are more likely to develop tuberculosis and fare poorly because of this allergy. Quite the contrary view is held by many. You neglected to mention that many careful students of the subject including Parke Krause, Opie and Heimbeck, are convinced that there is developed within the individual simultaneously a relative degree of immunity to the disease and if he should contract it a certain amount of resistance.

In discussing this subject Myers (*Am. Rev. Tuberc.* 27:121 [Feb.] 1933) quotes the work of Heimbeck who showed that of 185 pupil nurses who had negative tuberculin reactions when they entered training fifty-three contracted the disease, whereas among 152 classmates who were positive but three developed tuberculosis. Surely this does not show any particular predilection for the disease among those who have had a previous experience with tubercle. The same author, Myers in a previous publication (*Recent Facts on Transmission of Tuberculosis*, *The Journal* Aug. 1, 1931, p. 316) describes seven cases that had recently come to his attention among nurses and medical students none of whom reacted to tuberculin at the beginning of their training but who soon acquired the infection together with symptoms of the disease when they were assigned to a tuberculosis hospital. Obviously the fact that they had not been previously infected was no asset to them, no mention is made of their classmates who had positive reactions, but probably their experiences were more favorable.

Opie (*Tr. Col. Phys. Philadelphia* 1927) draws the conclusion that 'Latent tuberculosis of childhood confers immunity against subsequent infection, but resistance is limited and transient. Pulmonary tuberculosis of adults is not derived from the disease of childhood, but it is the result of new infection and pursues a chronic course because some immunity induced by preceding disease still persists.' Willis (*Am. Rev. Tuberc.* 17:240 [March] 1928) has shown in animal experimentation with the tubercle bacillus that relative immunity and resistance increased with the virulence of the organism, that they receded with healing of the infection but that they still persisted in latent form and that they were immediately reactivated by reinfection. Such resistance is illustrated very effectively in those people who develop the exudative lesion described by Wessler and Jaches and who are able to heal it entirely with an absence or minimum of symptoms, also in those with productive lesions which remained stationary or progressed slowly over a great many years allowing the patient to lead a comfortable and useful existence.

I feel that it is decidedly objectionable to broadcast the statement that the person who reacts positively to the test is a potential case of a reinfection type of tuberculosis because of the implication that such people are in danger of developing tuberculosis. It is true that no one possesses absolute immunity to the disease but it has yet to be shown that those who have had a primary infection are more likely to succumb than those not so infected. It is contrary to the facts as they are known, else how explain the fact that in large cities with an overwhelming proportion of the population infected the mortality rates are so relatively low?

It is my impression that the amount of tuberculin generally used in testing is 0.1 mg. Assuming this to be the case I think your statement 'The dose of tuberculin used in testing school children causes no harm whatever, even if the child has a reinfection type of disease' is one to which many pediatricians would take issue for the feeling is distinctly held by many that it may reactivate dormant bacilli and may cause a spread in active lesions. One not infrequently observes a large local inflammatory area, sometimes even vesicle formation at the site of inoculation and a rise in temperature, it is reasonable to suppose that such local and constitutional reaction is coexistent with the stimulation of the original focus in the lung or hilus.

The views expressed in your answer are contrary to those held by many prominent phthisiologists. One would think that in discussing such a subject these opposing opinions should be stated in order to avoid presenting to the medical public one extreme view of a controversy.

John Francis Cross, Yakima, Wash., Creighton University School of Medicine, Omaha, 1921, member of the Washington State Medical Association, aged 39, died, June 29, of coronary thrombosis.

Peter V. Faucher, Quebec, Que. Canada, Laval University Faculty of Medicine, Quebec, 1887, professor of materia medica and therapeutics at his alma mater, aged 69, died, July 3.

James Randall Wilder, Washington, D. C., Howard University College of Medicine, Washington, 1888, aged 68, died, July 7, of chronic duodenal ulcer, stenosis and pulmonary edema.

Bernard Francis McDermott, Los Angeles, College of Physicians and Surgeons, Baltimore, 1897, aged 61, died, June 8, of cerebral thrombosis and chronic nephritis.

John Martin Helgesen, Beloit, Wis., College of Physicians and Surgeons, Keokuk, Iowa, 1897, aged 61, died suddenly, July 25, in Cassville, of cerebral hemorrhage.

William L. Higginbotham, Sherman, Texas, University of Tennessee Medical Department, Nashville 1891, formerly a druggist, aged 77, died, July 13, of heart disease.

George Higginson, Nashville, Tenn., Vanderbilt University School of Medicine, Nashville, 1891, aged 69, died, August 15, of pulmonary abscess and Parkinson's disease.

Frank Hiram Edwards, Los Angeles, Chicago Homeopathic Medical College, 1895, Rush Medical College, Chicago, 1901, aged 61, died, August 17, of heart disease.

Edward Stephen O'Brien, San Francisco Medical College of the Pacific, San Francisco, 1879, aged 80, died, June 1, of chronic myocarditis and bronchopneumonia.

Joe Elmer Widner, Chicago, Niagara University Medical Department, Buffalo, 1890, aged 65, died, July 31, of chronic nephritis, arteriosclerosis and myocarditis.

George H. Haas, Allentown, Pa., Hahnemann Medical College and Hospital of Philadelphia, 1887, aged 74, died, July 20, of carcinoma of the intestine.

Walter Louis Perrott, Palo Alto, Calif., Cooper Medical College, San Francisco, 1898, aged 69, died, June 30, of myocarditis and cirrhosis of the liver.

Benjamin Blake Dutton, Hartfield, Va., Washington University School of Medicine, Baltimore, 1872, aged 83, died suddenly, July 6, of heart disease.

William H. Snively, Tampa, Fla., Medical College of Ohio, Cincinnati, 1881, aged 82, died, July 26, of cerebral hemorrhage and arteriosclerosis.

Harbard Smith, Smithville, Ga., University of Georgia Medical Department, Augusta, 1893, aged 74, died, July 12, of arteriosclerosis and uremia.

Bennett Clark Hyde, Lexington, Mo., University Medical College of Kansas City, 1895, aged 62, died suddenly, August 7, of cerebral hemorrhage.

Charles Maynard Smith, Johnsonburg, N. Y., University of Buffalo School of Medicine, 1888, aged 69, died, July 9, of paralysis agitans.

Robert Crosby, Vancouver, B. C., Canada, University of Toronto Faculty of Medicine, 1898, aged 64, died, July 5, of angina pectoris.

Alice Morgan Goss, San Francisco, Hahnemann Medical College and Hospital, Chicago, 1890, aged 78, died, June 26, of myocarditis.

Charles Stillman Mann, San Francisco, University of California Medical Department, San Francisco, 1890, aged 70, died, June 15.

Charles Sylvester Maguire, San Francisco, University of California Medical Department, San Francisco, 1893, aged 63, died, June 14.

James M. Hensley, Bellaire, Ohio (licensed in Ohio in 1896), aged 82, died, July 25, in Springfield, of cerebral hemorrhage.

L. Anna Ballard, Lansing, Mich., Woman's Hospital Medical College, Chicago, 1878, aged 86, died, August 23, of angina pectoris.

Samuel A. Wright, Hallandale, Fla., Northwestern Medical College, St. Joseph, Mo., 1883, aged 91, died, July 25, of uremia.

Harriet Herr, New York, Eclectic Medical College of the City of New York, 1889, aged 65, died, July 21, of uremia.

Charles Curtis Bliss, Pasadena, Calif., Bellevue Hospital Medical College, New York, 1874, aged 83, died, June 26.

Frank Ellsworth Lane, San Diego, Calif., Tufts College Medical School, Boston 1898, aged 68, died June 29.

In the article by Opie previously referred to he states that the significance of the reaction diminishes with increasing age. It is widely taught that the tuberculin test is of value in infants and young children because of its aid in detecting primary tuberculous lesions and because it may thus help to point out an infecting adult it is of value in older children because of its aid in detecting lesions although in these children they are exceedingly benign as a rule it is of value in adults because of its aid in excluding tuberculosis when negative, but when positive in an adult who shows no lesion on roentgen examination it is of no significance. It indicates only that at some period of life tubercle existed in the individual.

My object in writing this is not to urge that early tuberculinization of the entire population would solve all our problems but to call attention to the fallacy of the suggestion that the individual who shows a positive reaction is in danger of developing pulmonary tuberculosis. It seems to me that there is a more rational and reasonable middle path.

E. W. BILLARD, M.D., New York.

ANSWER—There is a source of tubercle bacilli for every child or adult who reacts positively to the tuberculin test. If one makes careful observations, the positive test in a child often results in finding the open case of tuberculosis.

It is true that Edwards (*Am. Rev. Tuberc.* 27:611 [June] 1933) found only one case of adult pulmonary tuberculosis in eighty-one families in which the first diagnosis was of a childhood form. However, he does not state how many previous deaths had occurred from tuberculosis in those families. Moreover, 45.5 per cent of the living members of those families were not examined. If all had been examined, and still only one case of open tuberculosis was found, it would have been worth the effort, since a single open case may transmit tubercle bacilli to hundreds of persons in a community. However, Edwards' group yielded a much smaller incidence of pulmonary tuberculosis than the groups studied by most other workers. For example, Rathbun (*Tr. Nat. Tuberc. A.*, 1929) made careful examinations of twenty-four families in which a school child was found to have the childhood type of tuberculosis. He found that in 54 per cent a parent was at that time ill with tuberculosis or had died of the disease, while in another 17 per cent parents had suspicious lesions.

There is no doubt that children rather often contract their disease from tuberculous patients outside their families, but even here when one seeks the source among school teachers and other associates one is quite frequently rewarded by finding it. Jordan has recently brought to light some interesting facts concerning the exposure of children by teachers. In fact, in his rural district he has found eleven teachers with frank tuberculosis, most of whom had never previously had their disease suspected. Seeking the source of the positive tuberculin reactor's lesion frequently takes the physician to the food handlers and other persons who come in contact either directly or indirectly with the public. It may also take him to the veterinarian, who sometimes finds the source among dairy cattle.

To be sure, the more recently the reaction makes its appearance, the easier it is to find the source. This is true not only of infants and children but also of adults who have been periodically negative to the tuberculin test. If the test is administered from every six to twelve months and it becomes positive, it is obvious that the exposure time is not far distant. It is much easier to trace the source in such a case than in one whose test has been positive for many years. Nevertheless a careful search should be made for the source of every positive tuberculin reactor.

Evidence is at hand to show that children who are sensitive to tuberculin are more likely to "develop tuberculosis and fare poorly" than those previously negative to the test. Myers has recently shown that among the first 1,000 children examined at the Lymanhurst School for Tuberculous Children in 1921 and 1922 of those who could be traced up to 1934, approximately one half had positive tuberculin reactions in 1921 and 1922 and the other one half reacted negatively at that time. Of the positive reactors traced, 9.65 per cent had or have since developed clinical tuberculosis, whereas only 1.08 per cent of those originally negative to the test have developed this form of disease. The average age of these children examined in 1921 and 1922 is in 1934 only 20.8 years. Therefore they have not attained the age when the greatest destruction occurs from tuberculosis.

Chadwick has found that children with positive tuberculin reactions and evidence of the first infection type of disease manifested roentgenographically provide five times as many clinical cases of tuberculosis within the next five years as those who had only positive tuberculin reactions on the original examination. It appears, therefore, that where actual observations have been made there is abundant evidence that the child with the positive tuberculin reaction, which always means a first infection type of tuberculosis, is not as good a risk as the child with a negative reaction. On the basis of what has

already been observed, it is estimated that from 10 to 20 per cent of the children with positive tuberculin reactions will be found to have or will develop clinical tuberculosis before they reach the age of 45 years.

Therefore is it decidedly objectionable to broadcast the statement that "the person who reacts positively to the test is a potential case of a reinfection type of tuberculosis"? No one has questioned the conclusions of Park, Krause, Opie, Heimbeck, Willis, Wessler and Jaches, and many others concerning the development of a relative degree of immunity in tuberculosis. In the previous communication the work of these authors was not omitted because of neglect but because it was assumed that their point of view is understood by all.

Attention was called to the work of Heimbeck, who showed that, of 185 student nurses who had negative tuberculin reactions when they entered training, fifty-three "contracted the disease," whereas among 152 classmates who were positive only three developed tuberculosis. In fact, all of the 185 who had negative reactions on admission contracted the disease before graduation, that is, they contracted the first infection type of tuberculosis, as manifested by a positive tuberculin reaction. In only fifty-three of them were there symptoms or demonstrable lesions by other phases of the examination. In fact in thirty-seven erythema nodosum was present, in twenty-two pleurisy was present, and so on. In some, more than one symptom was present. Among those who had pulmonary infiltrations demonstrated, Heimbeck called attention to their characteristics, which were for the most part those of the first infection type of tuberculosis. Thus, this group of 185 girls largely because of their exposure to tuberculosis in line of duty went through in Dr. Heimbeck's presence what the 152 who entered his institution sensitive to tuberculin had gone through before they came to him. The three with positive reactions on entrance could develop only the reinfection and destructive type, which is a far more serious matter. Here the time interval comes into play also. The first infection type may be manifested within three weeks after exposure yet the reinfection type may not develop to detectable proportion for months and even years after reexposure so that the three cases in this class by no means represent the end of the story. Further follow up in the years to come will give a different outcome. This can be predicted since sufficient numbers of cases have been followed now, and the course of their tuberculosis recorded, to justify an estimate of the ultimate morbidity.

The same oversight as to type of disease developed is true in the seven cases cited by Myers (*THE JOURNAL*, Aug. 1, 1933). As for statistics on the outcome of the two classes, that is, positive and negative reactors, the best study available is by Shipman and Davis (*Am. Rev. Tuberc.* 27:474 [May] 1933), who showed that more students who entered with positive reactions fall ill within the next ten years than those who entered with negative reactions. Since the characteristics of the first infection type of disease are the same at all age periods, it is safe to assume that the outcome of the disease in students of nursing and medicine everywhere will approximate the outcome in the children examined at the Lymanhurst School, which has been cited, that is, positive reactors had or developed clinical tuberculosis in a ratio of 9 to 1 with negative reactors over a period of eleven or twelve years.

It would appear that the first infection type of tuberculosis has been looked on as a great protection to the body when in reality the natural protective mechanism of the body deserves most of the credit. If it were not for this natural protective mechanism of the human body, most certainly tuberculosis would destroy far more people than it does. When tubercle bacilli first enter the body and find lodgment in the tissues there is no allergy present. Therefore there is no specific reaction on the part of the tissues. The focus of bacilli is met as that of a foreign body. The attempt to wall it off through the proliferation of fixed tissue cells is well under way before allergy can be detected. This attempt is so successful as to bring the tubercle bacilli under control quickly and to hold them under control in a high percentage of cases. It is difficult to see how immunity is of great importance, since the protective mechanism was at work before there was time for immunity to develop. Nor can this control of the bacilli be explained on the basis of racial immunity, since Indian, Negro and Mexican children meet the first infection with tubercle bacilli with the same defensive mechanism and control it equally well. When tubercle bacilli subsequently reach the tissues, whether from exogenous or endogenous sources a specific reaction takes place. Many of the bacilli are fixed at the site of lodgment and because of allergy, necrosis and cavitation frequently occur, as well as fibrosis.

Careful observations have revealed that in many large cities there is not an overwhelming percentage of the population

infected with tubercle bacilli. Tuberculin tests administered to children and young adults in many cities have been a revelation to physicians, for they have shown that relatively low percentages have been contaminated. To be sure, in some sections of large cities, such as Philadelphia, one may find communities where very little has been done to protect against exposure to tubercle bacilli and where 80 per cent or more of the young adults react positively to the test. In the same cities, however, one finds other sections where considerable attention has been paid to communicable diseases, including tuberculosis, and where a relatively small percentage of the young adults react positively to the test. Evidently the reduced mortality from tuberculosis has gone hand in hand with the reduced incidence of positive reactors.

The initial dose of tuberculin has been carefully studied. Most of the workers who have used 0.1 mg. of old tuberculin as the initial dose are of the opinion that it does no harm. However, some believe that 0.01 mg. should be used as the first dose. It is true that the characteristics of a positive tuberculin reaction are an area of edema at and around the site of the injection, with an area of hyperemia surrounding the edema. Without such a reaction the test is not positive. There is no reason to judge that because of this local reaction a reactivation of the tuberculous focus will occur. The chief trouble seems to be that many physicians are confusing the intracutaneous test with a very small dose of tuberculin with the old subcutaneous test, in which a large dose of tuberculin was administered and in which the positiveness of the reaction was determined largely by constitutional symptoms and even demonstrable reaction round the tuberculous focus, as manifested by the appearance of or increase in rales or collateral inflammation demonstrated by the x-ray film. The pediatrician or physician in any other phase of medicine who has done only the occasional tuberculin test or none at all might take issue with the statement that the test causes no harm, but those who have performed thousands of tests will not take issue. The new pure protein derivative will probably replace old tuberculin and a standard dose and technic will be recommended.

The statement that the positive tuberculin test in an adult who shows no lesion on roentgen examination is of no significance and "indicates only that at some period of life tubercle existed in the individual" does not suffice. In the finding of the first infection focus of tuberculosis, which practically always results in a positive tuberculin reaction, the x-ray film is of little avail. By it, 75 per cent or more of the lesions are missed as demonstrated by Miller (*Am J Roentgenol* 26 191 [Aug] 1931) and others who have carefully studied x-ray films made ante mortem and compared the observations with what has been found post mortem. In reality, the positive test at any age in life indicates tubercle formation with living tubercle bacilli present, otherwise the test would not remain positive. To state to a patient that a positive reaction "indicates only that at some period of life tubercle existed in the individual" is very misleading. One should always add that tubercle still exists. The recent pathologic observations of Robertson (*Am J Pathol* 9 711 [supplement] 1933) are convincing, particularly his concluding statement that "one can almost say 'Once infected, always infected'."

To argue for tuberculinization of the entire population and to bring this about would in all probability set the clock of tuberculosis back a century. When it probably was true that nearly every one had been infected with tubercle bacilli, the mortality rate from tuberculosis in this country was extremely high, for example, a century ago approximately 450 persons from each hundred thousand of population lost their lives from tuberculosis every year, whereas at present when the incidence of positive reactors among persons of high school and even university age has dwindled to 25 or 30 per cent the mortality has decreased to an almost unbelievable figure, in fact, less than 50 persons among each hundred thousand of population lose their lives from tuberculosis each year in many parts of this country. It is difficult to see "a more rational and reasonable middle path" since it is true that positive tuberculin reactors provide practically all the cases of clinical tuberculosis.

#### EFFECTIVE TREATMENT FOR BEE STINGS

To the Editor—Is there any effective treatment for bee stings other than local applications, which may aid in combating the more severe reactions that sometimes occur?

P. N. L., Chicago

ANSWER—In the June 1934 issue of *Bees and Honey*, page 117, the use of epinephrine intramuscularly or intravenously in a dosage of 1 cc. of 1:1,000 solution is recommended for the treatment of bee stings. It has been recognized for some time that there is a local and sometimes a general allergic reaction following bee stings which may be due to

pollens, formic acid or some atopic substance inoculated at the time of the sting. The general reaction is typically allergic, consisting of labored breathing, urticaria, edema, or any of the characteristic symptoms. As might be expected, epinephrine is said to provide the same relief in this sort of reaction as it does in reactions to other foreign proteins. While epinephrine is preferable for the relief of acute symptoms, for prolonged relief the oral administration of ephedrine suggests itself in a dosage of from 0.025 to 0.1 Gm. (one-half to 2 grains). This treatment may afford considerable relief if instituted as soon as any unusual or untoward symptoms appear following the stinging. Probably the treatment is equally applicable to stings or bites of a number of other insects as well.

#### EFFICACY OF RABIES VACCINE

To the Editor—Please state in what percentage of cases prevention of rabies is obtained by the administration of the Semple rabies vaccine in human beings and animals that have been bitten by a rabid dog.

M. D.

ANSWER—There is, of course, no way of determining how many deaths from rabies would have occurred without prophylaxis, but the efficacy of the Semple vaccine (phenol killed) as compared with others is indicated by the following tabulation of the latest figures available relating to mortality according to the method of treatment among Europeans given prophylaxis against rabies.

Method	Number Treated	Deaths	Mortality per Cent
1. Dried or glycerinated cords	25 600	47	0.18
2. Modified dilution methods	19 033	20	0.11
3. Killed phenol vaccines	19 196	22	0.11
4. Heated vaccines	27 967	32	0.11
5. Ether killed	31,034	32	0.10
6. Mixed treatments	28 659	36	0.13

When due consideration is given to various factors, such as position and severity of the bite and intervention of the clothing, there is no evidence beyond probable error to indicate superiority of any one of these methods of treatment (*Quart Bull Health Organization of the League of Nations* 2 553 [Dec] 1933). No figures are available as to animals bitten and subsequently given prophylactic treatment.

#### PROTEIN IN DIET IN HYPERTENSION

To the Editor—Each day I see patients who have hypertension particularly of the arteriosclerotic group. The question of diet always arises. If the function of the kidneys is not impaired as measured by the concentration test and the blood nitrogen, and if there is no edema I do not restrict the patient's protein or salt. Patients tell me that other physicians have kept them on a very strict diet and they hesitate to follow out my instructions. In fact, some of these patients have a secondary anemia from the restricted protein intake. Many patients are convinced that red meats (not white meat or fish) and salt are harmful to patients with high blood pressure. As a young internist I have been criticized for allowing my patients to have meat, eggs, fish and cheese under the conditions outlined. Medical teaching at my alma mater Washington University Medical School in St. Louis and recent literature have emphasized the necessity of at least two thirds to one gram of protein per kilogram of body weight daily. Even in cases of nephritis with albuminuria one gives a higher protein diet if the serum albumin is diminished. I am in charge of the diabetic clinic and diabetic service at the University of Tennessee Medical School and also teach dietetics to the senior medical students. Therefore I would appreciate a letter from you stating the present medical opinion regarding protein and salt in the diet of hypertension that I can read to the students. Please make a definite statement for the benefit of others regarding any difference between red and white meats.

JACOB ALPERIN M.D. Memphis Tenn.

ANSWER—The present consensus regarding dietary protein in hypertensive arterial disease is exactly along the lines indicated in the query. Extravagant claims have been made for the value of rigid protein restriction but equally convincing data are presented with liberal protein feeding. If the body does not obtain from two thirds to one gram of protein per kilogram of body weight daily the tissues are broken down to give this protein yield, the protein catabolism is not significantly depressed by protein starvation. Mosenthal has emphasized that restriction of carbohydrates and fats, particularly in obese hypertensive patients, is far more important than protein restriction. Liberal protein feeding does not appreciably alter the arterial tension. Long continued radical restriction of protein may do great harm by the depletion of the tissue reserves, exacerbation of anemia (common in arterial hypertension) and diminution of the resistance to infection. The recent work of Castle has reemphasized the necessity for adequate protein intake to prevent anemia. Although radical dietary restrictions are sometimes warranted for a short period, it must be constantly reiterated that unbalanced diets should not be per-

sisted in over a long period. In the management of hypertensive disease the dietary advice must be such that it can be safely followed over many months and perhaps years. This problem, then, is entirely different from the dietary management of an acute and transient illness.

In the presence of edema, and particularly when a profuse proteinuria occurs, liberal protein feeding to aid in replacing the depleted serum proteins is desirable. The early work of Epstein in this field has been repeatedly confirmed. The role of salt (NaCl) as an etiologic factor in hypertensive disease is as yet uncertain. There are some emphatic advocates of extreme salt restriction, but even more convincing contrary data have been presented indicating that moderate amounts of sodium chloride have no detectable influence on the course of arterial hypertension.

It is essentially immaterial whether the source of protein is meat, eggs, milk or cheese. There is no appreciable difference between the metabolic effects of "red and white meats."

The question is discussed in the following articles:

#### HYDROCHLORIC ACID IN HAY FEVER

To the Editor—I have read an article on the use of nitrohydrochloric acid in the treatment of hay fever. It says in this article that the relief obtained from the acid treatment is to be compared favorably with the pollen desensitization method. What is your opinion? I should like to know what dangers and contraindications this might give if used in the following prescription:

R Nitrohydrochloric acid 4½ fluidrachms  
 Distilled water q s ad 4 fluidounces  
 Sig One teaspoonful in two thirds glass of water followed by glass of water four times a day  
 Please omit name M D Massachusetts

ANSWER—This prescription is similar to that advocated by Beckman (*J Allergy* 1 496 [Sept] 1930, Treatment in General Practice, Philadelphia, W B Saunders Company, 1934) for the treatment of hay fever, it is not dangerous. Beckman reported 67 per cent of complete or marked relief in 237 hay fever cases by the oral administration of nitrohydrochloric acid, this figure was about equal to that obtained by leading allergists with the usual desensitization method of injections of specific pollen extracts. Many other workers have argued this point both before and after Beckman's article and the consensus, especially among the leading allergists, is about as follows:

1 No one has proved that hay fever or other allergic disease is due to a lack of acid (i e., an alkalosis), even though there is evidence that many allergic individuals do have less hydrochloric acid in the stomach contents than normal persons.

2 Although the method has been tried by many allergists, in general it has not been successful in alleviating the symptoms of hay fever. One commonly overlooked point is that hay fever symptoms are directly proportional to the pollen count. On days when there is little or no pollen in the air any method

of treatment is excellent and is apt to be called "curative", but when the pollen count is high, symptoms will be greater—that is the time to evaluate the method of treatment.

The intravenous injection of dilute hydrochloric acid recently advocated in allergic conditions is not without danger, its usefulness in these disorders is quite questionable.

#### TREATMENT OF SYPHILIS

To the Editor—A man aged 38 first came to me in August 1933 complaining of a discharging mass on the lower right mandible. Roentgen examination gave negative results. The Wassermann reaction was 4 plus. The spinal fluid Wassermann reaction also was negative. I started off by giving him ten injections of iodobismutol biweekly, at the end of which time the lesion on the mandible had entirely cleared up. I continued to give him one injection of iodobismutol and one of neoarsphenamine weekly for six weeks and the one injection of neoarsphenamine weekly for four more weeks. This brought me to the end of the year 1933 and the Wassermann reaction was 4 plus at this time. I continued to give one injection of neoarsphenamine and one of iodobismutol weekly, but at the end of two weeks the urine showed a very faint trace of albumin from 10 to 20 red blood corpuscles per high power field, an occasional white blood corpuscle and occasional hyaline and granular casts. I stopped the neoarsphenamine injections but continued the iodobismutol for four more weeks. The urine cleared up by the end of this period and I continued to give one neoarsphenamine and one bismuth injection weekly for six weeks. But at the end of two weeks the urine was as before and I stopped the neoarsphenamine giving only iodobismutol twice a week up to the present. The Wassermann reaction is still 4 plus. Only once at the end of the first ten weekly bismuth injections was the Wassermann reaction 3 plus. Clinically he shows no signs and gives no symptoms. His general condition is good. His weight has increased about 10 pounds (4.5 kg) since I first saw him. The total amount of neoarsphenamine that the patient has received thus far is 10 Gm covering seventeen injections and twenty-eight injections of iodobismutol all within a period of seven months. His longest rest period was five weeks. On and off during this continuous treatment he received iodides by mouth. Is this treatment too concentrated? Is another lumbar puncture indicated? Shall I continue with these drugs or can you suggest any others? Can I consider this a case of Wassermann fast syphilis? Only since the last six weeks have I allowed him to have protected coitus with his wife (his wife's and daughter's Wassermann reactions are negative). Is this safe? Do you consider the urine picture bad enough to discontinue neoarsphenamine? Please omit name. N D, New York

ANSWER—The treatment given this patient is not too concentrated for the average individual in early middle age with late syphilis. For this particular patient the signs of kidney irritation suggest that in this instance it may be too much. Renal irritation is definitely more frequent when the arsphenamines and heavy metals are given simultaneously than when they are given in alternate courses. Bismuth is somewhat more likely to produce renal irritation than neoarsphenamine. With the urinary condition found here it would be wise to discontinue all treatment for a time in order to observe the effect of a prolonged rest period on the kidneys. At the same time it would be desirable to have information as to the patient's blood pressure, the presence or absence of edema, the state of the eyegrounds and the results of such tests for renal function as the phenolsulphonphthalein excretion, the ability of the urine to concentrate solids (Mosenthal test), and the degree of nitrogen retention in the blood, if any. If there are no alterations of renal function and no constitutional symptoms of nephritis or nephrosis, and if the urinary abnormalities clear up promptly as soon as treatment is stopped, it may be assumed that these abnormalities are due to renal irritation from anti-syphilitic drugs. It would be desirable to allow a rest period of at least a month after the urinary changes have disappeared and to start treatment then with neoarsphenamine alone in small dosage, from 0.2 to 0.3 Gm, increasing by small increments of 0.1 Gm each, with frequent examinations of the urine. If renal irritation does not appear again with a dosage of 0.6 Gm of neoarsphenamine, it will be safe to continue with this level. After eight or ten injections of neoarsphenamine this drug should be discontinued and a bismuth compound started, with the same careful control of the urine. In a patient with previously undamaged kidneys, it is unlikely that either neoarsphenamine or a bismuth compound in the dosage employed will produce any serious or permanent kidney injury and it is probable that continued treatment with alternate courses of neoarsphenamine and a bismuth compound can be carried out without further difficulty.

Since the patient's blood Wassermann reaction has been persistently positive for eight months, it is reasonable to assume that he is Wassermann fast. Under these circumstances his treatment should be continued for an arbitrary minimum of two years if possible, during which he receives the equivalent of six or eight courses each of an arsphenamine and a heavy metal, without reference to the response of the blood Wassermann reaction. It is not necessary to do another lumbar puncture.

If the indication given in the query that the patient has late syphilis is correct, if he has been married for some years and if his wife is not already infected, there is no reason why unrestricted sexual intercourse with or without protection should not be permitted. The chief danger of infection under such circumstances is seminal, and the possibility of this has been either abolished or largely minimized by the treatment already given.

#### ARCUS SENILIS IN COLORED RACE

*To the Editor*—A Negro aged 59, presents a marginal opacity of the cornea about 1 mm in width (arcus senilis). While the condition is ordinarily attributed to senile degeneration of the corneal tissue the history of exposure of the face to intense heat covering a period of about fifteen years brings up the question of causal relationship. Is it possible that heat may be considered an etiologic factor or is it true that arcus senilis appears at an earlier age in the Negro? Please omit name.

M D, Wisconsin

*ANSWER*—Although there have been no publications dealing with this question, it is perfectly true that arcus senilis appears frequently at an earlier age in the colored than in the white race. This statement is made on personal observation and on verbal communications from several ophthalmologists who have had the opportunity of seeing large numbers of colored patients. The investigations of Verse and Rohrschneider, Vogt, Guido Meyer and others have shown that an arcus senilis is the result of lipid infiltration of the periphery of the cornea that it begins histologically before a clinical diagnosis is possible, and that it may appear in arcuate or complete ring form. If the former, the regions of the upper and the lower limbus are more apt to be involved than the lateral regions. Thus the involved areas are those covered by the lids and consequently protected against extremes of heat and cold. The etiologic factors are entirely unknown but it is fairly certain that heat has no part. A rather complete discussion may be found in the Kurzes Handbuch der Ophthalmologie by Schieck-Bruckner, volume 4, page 375.

#### DERMATITIS IN SILK INDUSTRY

*To the Editor*—A patient of mine operates a ladies underwear factory in which 'weighted silk' is used. He thinks that the silk is weighted with either tin or lead. He has noticed that some of his employees have developed a fine papular itching rash of the hands especially the tips of the fingers. The silks are dyed but the dyers state that no such skin irritations have occurred among their own employees. Can you suggest the possible cause of this rash or possibly let me know whether you have had any similar communications from like industries?

JACOB KINCOV, M D, Easton Pa

*ANSWER*—From time to time items are published attributing a dermatitis among silk workers to various causes. Among possible causes are tin tetrachloride, formic acid, dyes, sodium silicate, barium salts, dextrin, glues, linseed oil, Japan wax, sodium toluene-parasulphonchloroamide, vegetable mucilages, liquid petrolatum and rubber solutions. These substances, together with others, many of which constitute secret formulas, may be used in the weighing, finishing, plumping, sizing, luster-ing, delustering and dyeing of silks, natural or artificial. Little warrant exists for the picking out from this list of any one or two substances and placing on them greater blame as the source of the dermatitis. However, when tin tetrachloride or formic acid is used, some suspicion is possibly justified. Rarely an individual case may be traced to the dye, sensitization having taken place. Whatever hazards exist are greater for the silk worker than for the silk wearer, since the first laundering often sadly changes the appearance of silken garments which apparently are sometimes chemically dressed up for sales appeal. While the creation of systemic lead poisoning by lead originating in the wearing of lead weighted garments remains unproved, injury to the skin from various agents placed on the silk or artificial silk fiber may be more of a reality, especially among silk garment makers daily handling unlaundered washable articles.

#### FISSURES OF LIPS

*To the Editor*—What is the best treatment for a persistent fissure on the lower lip of the mouth? This fissure occurs each winter. The patient is a young married woman apparently in the best of health.

C E JOHNSON, M D St Paul

*ANSWER*—Fissures usually occur in skin that has lost its elasticity and extensibility through infiltration and thickening. They are found frequently about the mucocutaneous orifices, especially in eczema, syphilis, intertrigo and keratoderma. In persons using false teeth they are common at the outer angles of the mouth.

When they are associated with a seborrheic dermatitis, a sulphur ointment with a resorcinol lotion has been reported as helpful.

When it is closely allied to chapped lips, a red pomade consisting of tannic acid, 0.2 Gm., and cerate of red spermaceti, 10 Gm., to be used as a lip pomade, has been highly recommended. This is not visible and renders the lips more resistant to irritation.

Sulphonated bitumen, 2 per cent in hydrous wool fat, has been found helpful. Inunction with pure white hydrous wool fat may be sufficient.

It is important to avoid irritating washes, soap and water, tobacco and moistening the lips with saliva.

Fissures of the lip are sometimes rebellious and excision may be necessary with removal of a wedge shaped area including the infiltrated portion of the lip followed by accurate suture. No deformity should result.

Under expert hands, roentgen irradiations and diathermy might also be considered, but ordinarily skilful excision would be preferable.

#### REACTION TO IMMUNOGENS

*To the Editor*—A little girl 7 years of age presenting a chronic low grade infection of the accessory sinuses (as evidenced by general haziness of antrums and anterior ethmoids in roentgenograms postnasal and prenasal drainage and coughing when in the recumbent position) was given what might be considered subreaction doses of catarrhal immunogen (Parke Davis) on biweekly visits. The doses given were 2 3 4 6 and 8 minims (0.12 0.18 0.24 0.36 and 0.5 cc.) five doses in all. No complaints were registered until the fourth dose was administered when there followed slight general malaise for about thirty six hours with moderate local reaction, no elevation of temperature was detected. Following the last dose some general malaise and impairment of appetite were noted. This continued and on the fourth day following the last injection the temperature rose to 102 F. There followed several loose bowel movements and some vomiting with the onset of this fever. These symptoms rapidly disappeared and did not return. The elevation of temperature continued for eight days ranging from 100 to 103.5. Some shifting headaches were complained of and some slight stuffiness of the right side of the nose. The child seemed bright during the entire illness without stupor prostration neurologic signs cough or nasal discharge. In fact the physical examination was entirely negative except for slight general redness of the pharynx and tonsils noted when the temperature was high. No swelling of these organs at any time and no palpable glands were noted. Repeated urine specimens were negative. The blood count on the fourth day of fever revealed 3650 white cells, 26 per cent lymphocytes, 11 per cent large mononuclears, 1 per cent basophils, 3 per cent myelocytes and 59 per cent polymorphonuclears. On the sixth day of fever the white count was 6450 cells with approximately the same differential count. Blood culture proved negative. The temperature fell by lysis on or about the ninth day. The absence of symptoms other than fever in this case prompted me to a consideration of the possibility of the accumulation of toxins from these injections. Could there be a slow constant liberation of neutralized toxins from a preparation of this sort? What local reactions the child had at the site of the injections disappeared rapidly. The symptoms for which the child was treated with the immunogen cleared up quickly and were entirely gone before the onset of the fever. A single injection of 4 minims (0.24 cc.) of this preparation was given three months previously but a reaction occurred of fever nausea vomiting and a severe sneezing fit with a severe local reaction and the parents preferred to forego further inoculation until the reported series was attempted. The late appearance of the fever and its continuation for nine days made this case of unusual interest. There is no allergy in the family background. Please omit name.

M D, California

*ANSWER*—Immunogen (Parke, Davis & Co.) may be a mixture of antigenic substances. It is not on the accepted list of New and Nonofficial Remedies. Its use as a remedy rests on empirical grounds supported by advertising propaganda. Whether it caused, directly or indirectly, any or all of the symptoms described in the 7 year old girl cannot possibly be determined.

#### RESIDENCE FOR PATIENT WITH PANSINUSITIS

*To the Editor*—What region do you consider the most favorable as a residence for one afflicted with chronic pansinusitis?

N J WEILL M D Pittsburgh

*ANSWER*—Places that have sudden and marked variations in temperature or a great deal of cold damp weather are usually considered unfavorable for sufferers from sinus infection. The ideal spot would be one where the temperatures vary but little and where it is quite warm and reasonably dry. Southern Arizona in the region of Tucson or Phoenix is good for these patients, especially during the winter. It must be said, however, that there is a rather sudden drop in temperature in the evenings, and in the summer the heat may be intense. For people who enjoy and thrive on hot weather, southern Arizona has proved favorable. The region of San Diego in southern California is good, for the temperature is warm, mild and equable. San Antonio, Texas, is also favorably located but is of course hot in summer. Sinus infections may occur anywhere, especially where sudden changes in the weather occur.

A person who lives in one of the regions mentioned is less likely to have frequent or severe exacerbations of the trouble. With this diminution in the frequency of the attacks, together with the beneficial effect of warm, balmy air, the mucous membranes of the nose and of the sinuses have a better chance to recuperate and to resist the infection. Besides the favorable climate, proper drainage of the sinuses should be instituted in chronic cases.

#### FUNCTION OF EPIGLOTTIS

To the Editor—A question has arisen in my speech courses as to the function of the epiglottis. Will you please state what is conceded to be the function of this structure in deglutition? I would appreciate your giving me some references on this subject. Please omit name.

M D, Brooklyn

ANSWER—The precise role of the epiglottis in deglutition is still somewhat obscure. It is generally held that the epiglottis, by being pulled or pushed down and backward in the act of swallowing, forms a lid on the glottis. But the glottis is closed by other mechanisms. This probably explains the fact that the swallowing of foods or liquids, without any of them entering the larynx, can go on in the absence of the epiglottis. On the other hand, observers have described actual back folding of the epiglottis in the swallowing act. The thyro-epiglottic and the aryepiglottic muscles will tend to place the epiglottis in this position, if they contract during swallowing. The pulling backward of the base of the tongue (due mainly to contractions of the hypoglossal and geniohyoid muscles) also tends to press the epiglottis back so that its free tip extends beyond the glottis, which, by another series of muscles, has not only been closed but also pulled up and forward so as to be partly covered by part of the tongue. Textbooks on anatomy that may be consulted are those by Gray and by Cunningham and, on physiology by Howell, by Starling and by Tigerstedt.

#### ARSENIC AND OPTIC INFLAMMATION

To the Editor—I have a patient who is getting intensive neosarsphenamine treatment for syphilis. He receives 0.9 Gm every week. In addition he gives himself injections of mercury. The treatment was started in the primary stage and has been going on now for eighteen months. He had a relapse six months ago, with a return of the secondary skin eruption. Ever since the inception of treatment he has had an injected conjunctiva in both eyes. There is no lacrimation, purulent discharge or photophobia. His eyesight is as good as ever and he has no ocular pain. Does this symptom mean that he is getting too much arsenic? And if treatment is kept up, would it affect his eyes in any way? Please omit name.

M D Michigan

ANSWER—It is possible that the injection of the conjunctiva is due to the long continued use of arsenic. Such cases have been reported (Simon, Krauss, Kleeberg, all cited in the *Kurzes Handbuch der Ophthalmologie* 7 173). An idiosyncrasy is undoubtedly present in such cases and the conjunctival hyperemia is merely a local manifestation of what elsewhere would be a skin exanthem. However, it is equally possible that the patient is suffering from a chronic conjunctivitis of other source. The indefinite use of arsenic has caused not infrequently an optic neuritis.

#### ARTIFICIAL INSEMINATION

To the Editor—I was much interested in the answer to the question on artificial insemination in *Queries and Minor Notes* (*The Journal* August 11, p 432). As I was probably the first to make these experiments on a large scale having performed more than 100 attempts I would like to add a few additional comments to the answer given with which I in the main agree. In the first place one should in every case first examine the female after coitus (Huhner test) to see whether the spermatozoa during normal coitus do or do not reach the uterine cervix and remain alive there. It is therefore obvious that artificial impregnation is not at all indicated if it is found that the spermatozoa get there by themselves during coitus. The second point which I deem important and which is the only objection I find in the answer is the amount of semen that is injected into the uterine cavity. There is no objection to injecting any amount of semen provided it is injected only into the cervix and about the cervical os but I consider it dangerous to inject 1 or 2 cc into the uterine cavity itself. No matter how gently or slowly this quantity is injected there is the danger of some of it being forced into the tubes and infection is possible. It must be appreciated that there is no known practical method to sterilize semen surgically without killing the spermatozoa. I have often advanced the theory that during normal intercourse there is some property in the genital secretions which allows the spermatozoa to pass into the uterine cavity and upward but holds back or kills the ordinary bacteria that may accompany the semen. When it is considered that during ordinary marital life intercourse is performed without any antiseptic or aseptic precautions without infection following, one must believe in the aforementioned provisions of nature. As another practical point it is advisable to apply the tenaculum to the lower cervical lip so that if any bleeding occurs either in the putting on or taking off it will not run over the cervical os and contaminate the semen.

MAX HUHNER M D New York

### COMING EXAMINATIONS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY *Written (Group B candidates)* The examination will be held in various centers throughout the country Oct 1. *Oral (Group A and Group B candidates)* San Antonio Texas Nov 13 16 Sec Dr C Guy Lane 416 Marlborough St Boston.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY *Written (Group B candidates)* The examination will be held in various cities of the United States and Canada Nov 3 Sec Dr Paul Titus 1015 Highland Bldg Pittsburgh.

AMERICAN BOARD OF OPHTHALMOLOGY San Antonio Texas Nov 13 Philadelphia June 10 Sec Dr William H Wilder 122 S Michigan Blvd Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY San Antonio Texas Nov 16 Sec Dr W P Wherry 1500 Medical Arts Bldg Omaha.

ARIZONA Phoenix Oct 23 Sec Dr J H Patterson 320 Security Bldg Phoenix.

ARKANSAS *Basic Science* Little Rock Nov 5 Sec Mr Louis E Gebauer 701 Main St Little Rock.

CALIFORNIA Sacramento Oct 15 18 Sec Dr Charles B Pinkham 420 State Office Bldg Sacramento.

COLORADO Denver Oct 2 Sec Dr Wm Whitridge Williams 422 State Office Bldg Denver.

CONNECTICUT *Basic Science* New Haven Oct 13 *Prerequisite to license examination* Address State Board of Healing Arts 1895 Yale Station New Haven.

GEORGIA Atlanta Oct 9 10 Joint Secretary State Examining Boards Mr R C Coleman 111 State Capitol Atlanta.

IDAHO Boise Oct 2 Commissioner of Law Enforcement Hon Emmett Pfost 205 State House Boise.

ILLINOIS Chicago Oct 16 18 Superintendent of Registration Department of Registration and Education Mr Eugene R Schwartz Springfield.

IOWA Des Moines Oct 8 10 Dir Division of Licensure and Registration Mr H W Greffe Capitol Bldg Des Moines.

MICHIGAN Lansing Oct 9 11 Sec Board of Registration in Medicine Dr J Earl McIntyre 202 3 4 Hollister Bldg Lansing.

MINNESOTA *Basic Science* Minneapolis Oct 23 Sec Dr J Charnley McKinley 126 Millard Hall University of Minnesota Minneapolis *Medical* Minneapolis Oct 16 18 Sec Dr E J Engberg 350 St Peter St St Paul.

MISSOURI Kansas City Oct 24 State Health Commissioner Dr E T McGaugh State Capitol Bldg Jefferson City.

MONTANA Helena Oct 2 Sec Dr S A Cooney 7 W 6th Ave Helena.

NEBRASKA *Basic Science* Lincoln Oct 23 Dir Bureau of Examining Boards Mrs Clark Perkins State House Lincoln.

NEVADA Carson City Nov 5 Sec Dr Edward E Hamer Carson City.

NEW JERSEY Trenton Oct 16 17 Sec Dr James J McGuire 28 W State St Trenton.

NEW MEXICO Santa Fe Oct 8 9 Sec Dr P G Cornish Jr 221 W Central Ave Albuquerque.

NEW YORK Albany Buffalo Syracuse and New York Sept 24 27 Chief Professional Examinations Bureau Mr Herbert J Hamilton Room 315 Education Bldg Albany.

RHODE ISLAND Providence Oct 4 5 Dir Public Health Commission Dr Lester A Round 319 State Office Bldg Providence.

TENNESSEE Memphis Oct 12 Sec Dr H W Qualls 130 Madison Ave Memphis.

WYOMING Cheyenne Oct 1 Sec Dr W H Hassel Capitol Bldg Cheyenne.

### Minnesota June Examination

Dr E J Engberg, secretary, Minnesota State Board of Medical Examiners, reports the oral, written and practical examination held in Minneapolis, June 19-21, 1934. The examination covered 12 subjects and included 60 written questions. An average of 75 per cent was required to pass. Thirty-three candidates were examined, all of whom passed. One physician was licensed by reciprocity and 2 physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad	Per Cent
Northwestern University Medical School		(1934)	89.1
Rush Medical College		(1934)	85.5
University of Minnesota Medical School		(1931)	89.5
(1932) 91.5 * (1933) 85.4 88 * 88.2 90.1 90.6 *

\* This applicant has received an M B degree and will receive an M D degree on completion of internship.

### Oklahoma June Examination

Dr J M Byrum, secretary, Board of Medical Examiners, reports the written examination held in Oklahoma City, June 6-7, 1934. Sixty-five candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad
Northwestern University Medical School		(1934 2)*
Washington University School of Medicine	(1930, 2),	(1932)
University of Nebraska College of Medicine		(1930)
University of Oklahoma School of Medicine		(1934 58)†
University of Pennsylvania School of Medicine		(1933)

\* One of these applicants has received an M B degree and will receive an M D degree on completion of internship.

† Licenses withheld pending completion of internship.

## Book Notices

**Recent Advances in Sex and Reproductive Physiology** By J M Robson MD BSc FRSE Belt Memorial Research Fellow Institute of Animal Genetics. With foreword by Professor F A E Crew MD DSc FRSE Director of the Institute of Animal Genetics Edinburgh. Cloth Price \$4 Pp 249 with 47 illustrations Philadelphia P Blakiston's Son & Company, Inc, 1934.

This addition to the Recent Advances Series will be welcomed by many who want a brief discussion of some of the newer contributions to the physiology of the reproductive organs. Although the title does not indicate the limitation, this work is practically confined to a consideration of effects in the female. In this it cannot be said to attain completeness, which is not surprising in view of its brevity, and it may not be compared with such monumental volumes as *Sex and Internal Secretions*, edited by Edgar Allen. Such is the celerity of development in the field covered, indeed, that many of the discussions in the book are already out of date. Nevertheless, for a basic knowledge of the subject, Dr Robson's summary may be recommended to those who cannot or will not wade through weightier tomes.

In general the author has maintained an admirable attitude of skepticism and conservatism and, unlike many recent authors in endocrinology, he has analyzed the subject matter critically. Even in the section on therapeutic applications he points out the necessity for an adequate understanding of the hormone disturbances underlying a given clinical syndrome before endocrine therapy is attempted, although the methods of arriving at such an understanding, such as the tests advocated chiefly by Frank, are not properly emphasized. One serious criticism that may be made (and this applies equally to many other recent books) is that the nomenclature employed has not been edited with a view to preventing confusion. The multiplicity of active principles, the alleged identity of factors from various sources and the interests of commercial firms have led to the coming of a tremendous number of names. Many of these are synonymous or seem to be, others apply to two different principles once thought identical and more recently demonstrated otherwise or to two or more factors thought to be identical but not proved so. Thus has confusion been compounded. Unfortunately, authors of modern textbooks pay little heed to the necessity for rigid adherence to a nomenclature that provides not only for past contributions but for future developments as well. In this, writers might consider the report of the Council on Pharmacy and Chemistry on Estrogenic Substances (*THE JOURNAL*, April 29, 1933, p 1331), which demonstrates how adequate terminology may be applied in this fashion.

**Allgemeine Konstitutionslehre in naturwissenschaftlicher und medizinischer Betrachtung** Von O Naegeli Dr med Dr Jur H C Dr der Naturwissenschaften H C Second edition. Paper Price 15 marks Pp 190 with 32 illustrations Berlin Julius Springer 1934.

The problems of constitution in its relation to medical problems have expanded greatly since the first edition of this monograph appeared. It was the original purpose of the author to correlate information touching on problems of biology and medicine and the book was enthusiastically received by the profession. The style and purpose of the first edition have been maintained in this revision. The only change has been in bringing the material down to the present. It is concise and practical and the reader is not confused by a mass of conflict-

ing data. Because of the author's background in biology and clinical medicine he is able to present this subject to the physician in an authoritative manner. Some readers, especially those primarily interested in biology, may deplore the paucity of bibliographic references or discussion of the work of other investigators in the field. This, however, has undoubtedly been a purposeful omission to conform with simplicity in presentation. The monograph is carefully organized. In the first part the reader is given a comprehensive historical outline of constitution and disease. In the next part the author discusses some of the fundamental facts on variation, mutation, and modification of the species. The last part of the book is devoted to clinical application of these facts in the study of human disease and anomalies. Almost every phase of medicine has been touched on. Mutation problems in malignant tumors, mutation and its significance in bacteriology, constitutional factors in the various types of blood dyscrasias, and psychoneuroses from the standpoint of their constitutional background are concisely treated in a comprehensive manner. Few physicians who read this monograph will fail to be stimulated. It is a work that can be well recommended to both the biologist and the practitioner of medicine, for their interests merge on this important subject.

**Midwifery for Nurses** By Henry Russell Andrews MD BS FRCP Consulting Obstetric Physician London Hospital and Victor Lack MB BS FRCP Assistant Obstetric and Gynecological Surgeon London Hospital. Seventh edition. Cloth Price \$2.50 Pp 268 with 70 illustrations Baltimore William Wood & Company 1934.

This well known book has been ably revised by Victor Lack. The chief alterations are in the chapters on antenatal care, infection in labor, aseptic technic, puerperal sepsis and infant feeding. Data have been added concerning maternal mortality, stillbirths and anesthetics. The book is intended for nurses and nurse-midwives, and the subject matter is presented in a masterly way. It is unfortunate that rectal examinations are not even mentioned in the book. Nurses are instructed as to the proper way of making vaginal examinations during labor, but rectal examinations are certainly easier and usually less dangerous than vaginal examinations. In cases in which the cervix is fully dilated and the membranes are intact, the nurse is advised to rupture the membranes by scratching through them with the finger-tip while they are made tense by a pain. This procedure may not be easy with the gloved finger. Furthermore, the nurse should be cautioned not to rupture the membranes during a pain if the head is high up because the umbilical cord may prolapse. The authors recommend the use of castor oil on the second day after delivery. Most American obstetricians have given up the use of this laxative except for the induction of labor. In speaking of the treatment of placenta praevia the authors maintain that a nurse ought not to perform a version. Even in the hands of a physician, version in cases of placenta praevia is often a dangerous procedure. The popularity of the book is attested by the fact that it has been translated into three foreign languages, and this popularity will undoubtedly be retained in the British Isles and British dominions.

**Atlas of Selected Cases of Pathological Anatomy** By W M de Vries Professor of Pathological Anatomy at the University of Amsterdam. Cloth Price 25 Dutch guilders Pp 73 with 73 plates Amsterdam J H De Bussy Ltd 1933.

This atlas was dedicated by the author to the University of Amsterdam on the day of its tercentenary. The specimens used for illustration were chosen for various reasons—some because they were wanted for a publication, others because the pathologic condition was rare or characteristic, others again because the author could not find in the literature a good drawing of the condition. Most of the illustrations are in colors, but the artist has avoided using an excess of color, a fault that impairs the value of many atlases. There was no intention of composing a complete atlas of pathology but rather to select specimens for drawing that would have some value for clinicians and pathologists.

The drawings are grouped according to organs involved. Nineteen illustrations exhibit lesions of the heart and blood vessels. In this group are illustrated various forms of endocarditis syphilitic aortitis, malformations of the heart, canali-

zation of a thrombus, and a most unusual sarcoma of the veins of the leg. There are twelve illustrations of lesions of the lungs. The pictures of "the lung in Spanish influenza" are the only ones in the book that are too highly colored. Especially worthy of mention in this group are the drawings of two aneurysms in a tuberculous cavity, and the "so called lymphangitis carcinomatosa of the lung and pleura." Fifteen drawings are devoted to lesions of the liver and gallbladder. Of especial interest to surgeons is the picture of "necrosis (anemic infarction) in the right lobe of the liver after ligation of the right branch of the hepatic artery" during a difficult operation on the gallbladder. Eight drawings each illustrate lesions of the kidneys and of the brain and spinal cord. Special mention should also be made of the gross and microscopic illustrations of the spleen in Gaucher's disease, hemorrhagic necrosis of the mucosa of the rectum following the use of an enema that accidentally contained too much alcohol, chorioepithelioma in the male, and three remarkable illustrations of the head and skull in a case of generalized osteitis fibrosa in a chimpanzee.

Most of the illustrations are accompanied by a brief clinical history, a description of the specimen illustrated and the important items in the anatomic diagnosis of the case from which it was obtained. In many instances there are one or more references to pertinent literature. The text is in English. The typography and reproduction of drawings are excellent. This volume can be heartily recommended to clinicians and pathologists as a group of fine illustrations of significant pathologic conditions.

**Diagnostic clinique. Examens et symptômes.** Par le Dr A. Martinet. Avec la collaboration des Docteurs Desfossez, Georges Laurens, Léon Meunier, Lullei, Saint Côme et Terson. Sixième édition. Cloth. Price 145 francs. 1 p. 1138 with 875 illustrations. Paris: Masson & Cie 1934.

This book has established itself as a classic in the French medical literature. It presents a detailed description of the whole field of medical diagnostic science, written by the best known French authority on this subject. This edition has been completely revised by the collaborators of the deceased author. The work is divided into three parts. The first is devoted to general remarks, description of the evolution and present status of the diagnostic science and discussion of common causes of diagnostic errors, such as ignorance, incomplete examination or errors of judgment. History writing and physical examinations are described in an exhaustive and yet simple manner. The second part deals with the technique of examination of the respiratory, digestive, circulatory, genito-urinary and nervous systems. Special chapters are devoted to descriptions of bacteriologic technique, biologic tests, anthropometry, basal metabolism, interferometry, and acid-base equilibrium. The third part deals with symptomatology, separate chapters are devoted to the differential diagnosis of albuminurias, anemias, ascites, convulsions, hematurias, lumbago and jaundice. Newer laboratory and clinical methods, such as gastroscopy, interferometry, roentgenography of the spleen and liver, ventriculography and determination of venous pressure, receive a due consideration. The printing and paper are excellent, the style fluent, the text is amply illustrated by colored plates and numerous charts. The book may be considered a valuable and authoritative contribution to the French medical literature and can be heartily recommended to all general practitioners who read French.

**Manuel de radiodiagnostic clinique.** Par R. Ledoux-Lebard, chargé de cours de radiologie clinique à la Faculté de médecine de Paris. Fascicules I et II. Cloth. Price 260 francs. Pp. 1075 with 1143 illustrations. Paris: Masson & Cie 1933.

Especially to his numerous friends among the radiologists of the United States these two volumes serve as a pleasant reminder of the loyal and generous war-time service rendered by the author to the medical department of the American Expeditionary Forces. A subsequent lecture trip to this country a few years after the war served further to cement the warm friendship accorded him by a host of friends in America. These volumes constitute a notable contribution to radiology and stand easily as the foremost French publication of this sort. In the author's characteristic easy style the text offers no difficulty and much attraction to readers of French. The

pages devoted to physics are ample, and it is gratifying to see the generous space devoted to the various methods of localization of foreign bodies, a field in which the author excelled during the great war. It is often disappointing to note a surgeon seeking long and blindly in the glaring light of the operating room, interrupting his work at frequent intervals to study some roentgenograms on the side wall, in attempting to find and remove a foreign body that could be located and delivered in a short time by the aid of the fluoroscope, a training that was given to many American surgeons during the war but little taught and less practiced by the newer generation of physicians taking up surgery. In turning through the pages of these two volumes, chapter by chapter, one is impressed with the thoroughness with which the various subjects are discussed. If some disappointment is felt on account of the small size of the illustrations and the rather less than best reproduction of the roentgenograms, this feeling is pretty well offset by satisfaction in the completeness of the text and its general readability.

**Electrokinetic Phenomena and Their Application to Biology and Medicine.** By Harold A. Abramson, M.D. American Chemical Society Monograph Series No. 66. Cloth. Price \$7.50. Pp. 331 with 107 illustrations. New York: Chemical Catalog Company, Inc. 1934.

Many of the reactions characteristic of living cells are probably due to the fact that the molecules in the liquid-liquid and solid-liquid interfaces encountered in such cells are oriented in a specific manner. Because of this molecular orientation surfaces acquire specific properties that are of fundamental importance in the consideration and interpretation of all types of biologic phenomena. Some ideas concerning the structure of such interfaces may be derived from a study of the differences in electrical potential observed when there is tangential movement of one phase relative to the other. This potential is known as the electrokinetic potential and may be estimated by observing the mobilities of particles in an electrical field, as in electrophoresis, or the motion of the whole body of liquid, as in electro-osmosis. In the first chapter the author discusses the historical development of the subject. Chapters II and IV, on theory, will be found more useful and interesting by chemists and physicists who have had an adequate mathematical training than by the average biologist. In chapter III the author describes various methods available for the study of such electrokinetic phenomena as electrophoresis, electro-osmosis and streaming potentials. The reader interested in the application of these phenomena to medical and biologic problems will find interesting and suggestive material in chapters V, on proteins and related compounds, VIII, on organic surfaces, X, on blood cells, spermatozoa and tissues, and XI, on bacteria, antibodies, viruses and related systems. The average medical reader would probably find this book more useful if it were more descriptive and less mathematical. In its present form it requires special study, which will, however, repay the reader who is interested in the further development of this important field and the application of the results obtained to medical problems.

**Le phosphore. Techniques chimiques, physiologie, pathologie, thérapeutique.** Par M. Labbe, professeur de clinique médicale à la Faculté de médecine de Paris, et M. Fabrykant, assistant à la clinique médicale de la Pitié. Paper. Price 55 francs. Pp. 395. Paris: Masson & Cie 1933.

This work represents, in a well organized form, a compilation of numerous observations on the distribution of different forms of phosphorus in tissues, organs and body fluids under various conditions of health and disease. Although an attempt is made to emphasize the chemical aspects of the methods used, it is quite obvious that this is by no means critical from biochemical or analytic points of view. The data accumulated in some cases are necessarily of doubtful value because of the analytic methods used. Such important forms as phosphoproteins are ignored almost entirely, and nucleotides are stated to be hydrolyzed by phosphatases to phosphoric acid and "hydrocarbone purique ou pyrimidique." The various physiologic and pathologic aspects of phosphorus metabolism are reviewed under the following titles: experimental variations in blood phosphorus, variations in blood phosphorus as a result of the influence of substances influencing carbohydrate metabolism.

excretion of phosphorus, phosphorus in rickets, in hypervitaminosis D, in tetany, in acromegaly, in arthritis, in anemias, in leukemias, in diabetes, in liver diseases, in kidney diseases, in phosphaturia, and the therapeutic use of phosphorus. Here again is evidence of the lack of quantitative evaluation of the rather limited amount of experimental work on the different forms of phosphorus and their distribution. Thus, it is stated as a fact that, no matter what form of phosphate is fed, the phosphate is always absorbed in a relatively simple form and above all as inorganic phosphate. On the whole the compilations on pathologic and physiologic variations in phosphorus metabolism are valuable, but in the present state of knowledge, largely because of lack of adequate quantitative data on different forms of phosphorus, sweeping generalizations should be reserved until a future time. Each chapter is followed by an excellent list of references to original papers.

*Homosexualismo creador* Por A. Nin Frlas. Paper. Price 25 pesetas. Pp. 383 with 36 illustrations. Madrid: Javier Morata. 1933.

The author adopts the biologic and social aspects of homosexuality that for some years have been current in German and other publications; he has been greatly influenced by the "Psychopathia Sexualis" of Krafft-Ebbing, Havelock Ellis's "Sexual Inversion," and "Los Estados Intersexuales en la Especie Humana" by Gregario Maraño. He classifies the human race into two types, the so-called normal venereal men and women, with subspecies of urnings (male and female) and the types between these and the venereal class. The condition of homosexuality apparently is considered by the author as beginning in the uterus as a variant of the germ plasm. The author seemingly prefers to consider the pure urning rather as afeminine in feeling and emotions than as a sex aberration or as a sex inversion. It is a distinct biologic state.

The disdain of medieval and modern society for homosexual individuals has been responsible for their shunning sexual life altogether in many instances and sublimating their so-called abnormal sex life so that they are enabled to devote themselves without abstraction to the higher paths of human culture. They have been of aid to the feminist movement in that they have respected women though not attracted to them sexually, allowing them or helping them to attain sex emancipation. It is in this aspect that the author regards homosexuality as a creative force.

While there is nothing essentially new in reference to the biologic or social aspects of homosexuality as given by the author, his really valuable contribution to the subject is his study of the literary and other work by this rather extensive sex minority throughout the ages. These he illustrates by citations giving the names of the authors. The bibliography at the end will also be of value to those interested in this subject. The author spent many years traveling in Europe and elsewhere and personally verified all the incidents and works that he cites. Many of these are of the greatest interest.

One point which the author incidentally brings out should be mentioned, namely, that he considers the love between homosexuals to be on a higher plane emotionally and otherwise than that between heterosexuals.

*Formes chirurgicales de la tuberculose intestinale* Par L. Bérard, professeur de clinique chirurgicale à la Faculté de médecine de Lyon et N. Patel, professeur à la Faculté de médecine de Lyon. Paper. Price 50 francs. Pp. 264 with 69 illustrations. Paris: Masson & Cie. 1933.

Intestinal tuberculosis is so common particularly among patients suffering from pulmonary tuberculosis, that it is fortunate that Bérard and Patel have presented in this volume the results of their wide experience as well as the experience of many other workers. The book is unusually well prepared. It is concise and at the same time contains all the practical value that is known concerning this subject. The book is divided into ten main divisions, in which are discussed etiology, and pathogenesis, general anatomy and pathology, tuberculosis of the small intestine of the cecum of the appendix and ileocecal region and of the large intestine, intestinal tuberculosis as a complication with pulmonary tuberculosis, methods of diagnosis, treatment with indications and technic, and complications. Under the heading of diagnosis all phases of the examination are discussed, beginning with the search for tubercle bacilli in

the fecal material. Here the authors call attention to views held by different authors, one that the presence of tubercle bacilli in the feces is indicative of intestinal tuberculosis, another that practically all patients with pulmonary tuberculosis have tubercle bacilli in the feces. They emphasize the importance of special technic to recover tubercle bacilli, and guinea-pig inoculation. They assign considerable importance to the finding of blood in the stool, as well as pus. The authors consider the reaction of Triboulet of great value and call attention to recent work with this reaction. Considerable space is given to the roentgen examination and this section is well illustrated. Under treatment they consider all operative procedures, first, those which are palliative and, secondly, those which are radical. Here they deal with the various indications and contraindications for surgery and present several tables showing their results. This section contains good illustrations. Complications, such as fistulas, occlusion and peritonitis through intestinal perforation, are thoroughly discussed as to diagnosis and treatment. The book contains a large bibliography, which includes the studies of several North American authors, such as E. W. Archibald, Lawrason Brown and H. L. Sampson, and D. A. Stewart. The book is to be recommended not only to those particularly interested in intestinal tuberculosis and surgical procedures but also to those with more general interest in tuberculosis.

*Röntgenologische Studien über die traumatischen und habituellen Schultergelenkverrenkungen nach Vorn und nach Unten* Von Ivan Hermansson. Acta radiologica Supplementum XX. Paper. Price 9 Swedish crowns. Pp. 171 with illustrations. Stockholm: P. A. Norstedt & Soner. 1934.

This monograph contains the roentgenologic study of traumatic and recurrent dislocation of the shoulder, both forward and inferior or subcoracoid. The author reports ninety-two cases and offers a bibliography. Unfortunately, he has overlooked the work of Heymanowitsch and Nicola.

*Cours élémentaire de dessin d'anatomie du squelette* Par A. Moreaux. Paper. Price 10 francs. Pp. 34 with illustrations. Paris: Masson & Cie. 1934.

This booklet presents the elementary points in sketching the anatomy of the skeleton. It is interesting and simple. It was written for medical students, candidates for professorial degrees and students of the school of fine arts.

*Rheumaprobleme. Band III. Gesammelte Vorträge gehalten auf dem III. Arztekursus des Rheuma-Forschungsinstituts am Landesbad der Rheinprovinz in Aachen vom 22. bis 24. März 1934.* Von Geheimrat Prof. Dr. Aschoff und anderen. Herausgegeben von Dr. Walter Krebs, Chefarzt des Landesbades und Leiter des Rheuma-Forschungsinstituts zu Aachen. Boards. Price 5.40 marks. Pp. 95 with 21 illustrations. Leipzig: Georg Thieme. 1934.

The problem of rheumatic diseases has become such an important one that in many countries, as in the United States, special committees have been formed to organize and correlate researches and to foster conferences presenting the results. This volume contains the proceedings of the third German conference, held at the Rheuma-Forschungsinstitut in Aachen, March 22 to 24, and is a sequel to the proceedings of the first and second conferences of 1928 and 1930, published in 1929 and 1931 respectively. It is edited by Dr. Walter Krebs, chief of the government spa and of the Rheuma-Forschungsinstitut, and contains the following papers by its distinguished contributors: investigations on the causes of rheumatic myocarditis, Ludwig Aschoff, Freiburg; the significance of bodily constitution in the disease picture of rheumatism, Ernst Edens, Düsseldorf; roentgen therapy for diseases of joints, Rudolf Grashay, Cologne; a contribution on the relationship of periosteum and fibrous tissue to rheumatic diseases, Walter Krebs, Aachen; functional point of view and measures in the management of arthritis and arthrosis, Lothar Kreuz, Berlin; preliminary survey of advancements in the domain of rheuma research in later years, Franz Külsb, Cologne; present conceptions on our knowledge of the etiology of specific rheumatism, Paul Manteluf, Düsseldorf; a clinic on rheumatic infections with considerations on etiology and treatment, Hugo Schottmüller, Hamburg; medicinal and physical methods of treatment of "rheumatic" arthritis and arthrosis, Heinz Gehlen, Aachen; the management of myalgia and neuralgia, Hermann Hennes,

Aachen, the treatment of so called rheumatic diseases of the vertebral column, Oskar Vontz, Aachen

These publications on "Rheumaprobleme" should not be confused with another annual German review, *Rheuma-Jahrbuch* (Leo Alterthum, Berlin)

## Medicolegal

**Hospitals Liability for Injuries Notwithstanding Release from Liability of Person Responsible for Original Injuries**—The plaintiff received an injury to her vertebra in an automobile collision. She was taken to the defendant hospital and was attended by her own physician. After giving her a sleep-producing drug, the physician instructed a nurse employed by the hospital to apply an electric pad to the patient's spine in a manner directed by him. In the absence of the physician, the nurse applied the pad in a different manner and as a result the patient was badly burned. Subsequently, the patient, for a consideration, released the person responsible for the automobile collision from "all claims on account of injuries resulting, or to result, from" said automobile accident. She then sued the hospital solely for damages for the burns resulting from the negligence of the nurse. Judgment was given for the patient. From the trial court's denial of a motion for a new trial, the defendant hospital appealed to the court of appeals of Georgia, division no 2.

The hospital contended that the release given by the patient to the person responsible for the automobile accident operated to release the hospital from any damages for which it might be liable as a result of the burns. The court of appeals conceded that a release might have that effect if the patient's claim was based on the aggravation of the injuries sustained in the automobile accident. But because the patient sued because of injuries that resulted from negligence of the hospital employee that caused an injury separate and distinct from the original injury, the hospital was still liable, notwithstanding the release. The fact that the original injuries furnished the condition and gave rise to the occasion by which the injuries resulting from the hospital's negligence were made possible the court regarded as immaterial. The judgment in favor of the patient was therefore affirmed.—*Piedmont Hospital v Trinit (Ga)*, 172 S E 237

**Workmen's Compensation Acts Thumb Bruise Following Use of Paint Spray Gun**—In the course of his employment, the workman bruised his thumb by constant pressure on the button of a spray gun used in painting furniture. A physician lanced the thumb and subsequently a felon developed. To recover for the resulting disability, the workman instituted proceedings under the Virginia workmen's compensation act. The industrial commission denied compensation and the workman appealed to the Supreme Court of Appeals of Virginia.

For a disability, said the Supreme Court of Appeals, to be compensable under the Virginia compensation act it must be the result of an "injury by accident." The meaning of this term was recently construed by the Virginia court in *Big Jack Overall Co v Bray (Va)*, 171 S E 686 where, quoting from *McCauley v Imperial Woolen Co*, 261 Pa 312, 104 A 617, it was said:

If the incident which gives rise to the injurious results complained of can be classed properly as a mishap or fortuitous happening—an untoward event which is not expected or designed—it is an accident within the meaning of the Workmen's Compensation Act.

In this case there was no sudden unlooked for mishap. Some two hours before stopping work, the workman noticed that his thumb was somewhat red from the continuous pressure on the button. He continued to use the thumb in the same manner, with increased soreness and discomfort. The slightly bruised thumb was the origin or beginning, of the sequence of events that ended in its partial loss of use. The bruise was received while the workman was performing his duty in the usual and ordinary manner—a result, under the circumstance, ordinarily and naturally flowing from the conduct of the workman. It

cannot be held to be an "injury by accident" within the meaning of the compensation act. The judgment of the industrial commission denying compensation to the workman was affirmed.—*Hurd v Hesse & Hurt (Va)*, 172 S E 289

**City Hospitals Liability of City for Hot Water Bottle Burn**—The city of Owatonna, Minn, owns and operates a general hospital. Only pay patients are admitted to the hospital. Profits from the operation of the hospital are placed in a hospital fund and are not used for other city purposes. Following an appendectomy performed on the plaintiff at the hospital and while he was still under the anesthetic, his leg was burned by a hot water bottle, placed in his bed by a hospital nurse. He brought suit against the city of Owatonna. There was a judgment for the plaintiff and the city appealed to the Supreme Court of Minnesota.

The liability of the city, said the Supreme Court of Minnesota, depends on whether the city in operating the hospital was exercising a proprietary or a governmental function. If it was exercising a proprietary function, it is liable, if it was exercising a governmental function, it is not liable. In concluding that in operating the hospital the city was exercising its corporate proprietary powers, the court said that the hospital was not such a one the operation of which could properly come within the governmental function for the protection of health and suppression of disease. It was a general hospital operated for the private advantage and convenience of the inhabitants of the city. That its operation might incidentally to some extent protect society from sickness and death the court thought to be immaterial. When a city engages in activities which are of a nature ordinarily engaged in by private persons and which subject private persons to liability for negligence, the city is likewise liable for negligence. In Minnesota, owners of hospitals are liable for the negligence of their servants whether the hospital be maintained for profit or for charitable purposes. *Mullner v Evangelischer Diakonissenverein of Minn Dist*, 144 Minn 392, 175 N W 699. The judgment in favor of the plaintiff was accordingly affirmed.—*Borvege v City of Owatonna (Minn)*, 251 N W 915

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

**Intravenous Galactose Liver Function Test**—Jankelson and Lerner introduced galactose intravenously to test, indirectly, the extent of parenchymatous hepatic destruction if any was present. The patient is in a fasting state (overnight). In the morning a venous blood sample is taken and oxalated. Without removing the needle from the vein, a syringe containing 50 cc of a 50 per cent solution of galactose is attached and the solution is injected slowly over a period of from eight to ten minutes. Half-hourly, venous blood samples are taken for the next two hours. The authors employed the test in seven normal persons and eight patients having some pathologic condition of the liver. The results indicate that persons having a normal liver metabolize 25 Gm of intravenously injected galactose within sixty minutes. In pathologic conditions the same amount of galactose may or may not be metabolized during a like period. The delay in its utilization depends on the degree of damage to the liver. When the degree of damage is minimal, the rate of utilization may be normal. With increasing damage the utilization of galactose takes longer. The authors emphasize the fact that whereas the galactose liver function test of Bauer has no place in the diagnosis of liver disease in the absence of jaundice the intravenous galactose test may show a variable amount of sugar retention within the venous blood in liver disease not accompanied by jaundice as well as that with jaundice. In the small number of cases of jaundice observed by them the intravenous galactose liver function test was positive in all, whether the cause was within the liver or in the extrahepatic bile ducts. The intrahepatic type of jaundice, however, presented the highest retention of galactose and therefore if any differentiation by this test is possible at all it must rest on the degree of retention and not the absence or presence

of it. Negative intravenous galactose liver function tests do not exclude minimal liver damage but probably indicate a normal liver function.

**Intensified Oral Cholecystography**—Stewart and Illick outline a method of intensified cholecystography, combining the methods of Antonucci and Sandstrom, in which the patient is given several cups of tea with extra sugar during the afternoon. The regular evening meal is allowed at 6 p m and the first dose of tetraiodophenolphthalein is given at 7 o'clock. More tea with sugar is given later in the evening. No breakfast is given on the morning of the following day. Roentgen studies are made at twelve and sixteen hours after the first dose of the dye. The noon meal consists of fruit juices, jello, fruit salad and tea. Another dose of the opaque substance is given after this. In the afternoon more tea with excess sugar is taken, and in the evening a meal similar to the luncheon. The third dose is given in the evening, and the thirty-six hour examination is made the following morning. These thirty-six hour films demonstrate remarkable concentration of the opaque bile in the gallbladder, the opacity equaling that of a barium-filled stomach. Study then may be made following the usual fatty meal to determine how well and rapidly the gallbladder empties. A one-half second exposure time, with 100 milliamperes through a fine focus tube, is used. A special speed Bucky is employed. The diagnostic detail of the thirty-six hour roentgenograms demonstrates nonopaque gallstones well. The shadow intensity obtained at thirty-six hours is far more uniform than that formerly possible with the sixteen hour method. Faint gallbladder shadows are no longer a problem but conclusive evidence of dysfunction of the mucosa. "No shadow" cases do not need the customary check-up, as the observations are now much more dependable.

**Auxiliary Treatment for Impetigo Contagiosa**—Hollander and Hecht used metaphen 1 500 incorporated in flexible collodion in the treatment of 234 cases of impetigo contagiosa, ten cases of ecthyma and twenty cases of infectious eczematoid dermatitis. The surface of the skin surrounding the infected area was washed with soap and water and dried thoroughly with absorbent tissue. The lesion was painted with several layers of metaphen 1 500 in collodion, which was permitted to dry layer by layer. In twenty-four hours the easily removable layers of the metaphen-collodion mixture were removed with a tissue forceps. The adherent part was left on, and the mixture was reapplied in several layers. The procedure was repeated on the third day. On the fourth day all the metaphen-collodion preparation, which by that time had curled up at the edges, was removed and with it the underlying encrustation. If the underlying skin was dry, light anointing with 2 per cent ammoniated mercury was carried out. If, however, the surface was still moist, the metaphen collodion mixture was applied for another period of three days. Of the impetigo contagiosa cases 85 per cent were cured after an average of eight days of treatment, 75 per cent of the ecthyma cases after an average of fourteen days of treatment and all the cases of infectious eczematoid dermatitis after an average of twenty days of treatment.

**Lipoid Cell Pneumonia**—Goodwin observed twenty-five cases of lipoid cell pneumonia during the past ten years. In three of these the diagnosis was established clinically, in the others at necropsy. The ages of the children ranged between 6 months and 5 years. Various oils were responsible. Milk fat was perhaps the most frequent kind found. The children were weak or comatose and were fed by gavage, or vomited frequently, and the regurgitation of the milk was the cause of

the aspiration. Cod liver oil was present in the lungs in a number of infants, and in almost all there was the history of cough, vomiting or struggling against the administration of the oil. In four of the cases in which the amount of pulmonary involvement was the greatest, a clear history of the instillation of liquid petrolatum in the nose, or its ingestion, was obtained. The oil was identified in the lung in two instances. Rapid respiration without dyspnea and a persistent hacking cough stand out as the two most frequent complaints. A single roentgenogram is scarcely ever typical enough to do more than suggest lipoid cell pneumonia. The course of the disease is in most cases determined by the condition associated with it. There is as great a difference in the pathologic picture found at necropsy in cases of lipoid cell pneumonia as there is in the clinical picture. The author's observations confirm those of Laughlen and Pinkerton. Uncomplicated lipoid cell pneumonia offers a good prognosis. It should be suspected in small, debilitated infants who fail to gain weight and who have a chronic cough or rapid respiration. These symptoms, in the absence of fever, suggest lipoid cell pneumonia. Tuberculosis must be ruled out. The blood picture is normal in uncomplicated instances and is in conformity with the picture of coincident infections. The roentgenogram is of the greatest help. The consolidation is central, bilateral, more extensive on the right and apt to be posterior. The roentgen shadow is always more extensive than the amount of consolidation suggested by physical examination. Roentgenograms taken weeks apart may show scarcely any difference in the appearance of the lungs. The author has never seen cavitation in lipoid cell pneumonia or calcification in the bronchial lymph nodes. The tendency for the lesion to disappear gradually makes the picture unlike that of a neoplasm or congenital malformation, and the physical signs are rarely those of atelectasis. Good nursing with a frequent change of position and the avoidance of infection of the upper respiratory tract is the only treatment. It is unwise to use drops of oil in the nose of any small or weak infant, and liquid petrolatum as a cathartic should not be given. When cod liver oil is taken poorly, it is best to substitute one of the more concentrated vitamin D preparations. Care in feeding and gavage done only by experienced persons will decrease the incidence of pneumonia from the aspiration of foodstuffs.

**Defective Development of Corpus Callosum**—Davidoff and Dyke describe two cases of agenesis of the corpus callosum diagnosed during life. The diagnosis was based on the encephalographic observations and was confirmed by necropsy in a third case. The cardinal changes noted in the encephalograms of all three cases are (1) marked separation of the lateral ventricles, (2) angular dorsal margins of the lateral ventricles, (3) concave mesial borders of the lateral ventricles, (4) dilatation of the caudal portions of the lateral ventricles, (5) elongation of the interventricular foramina, (6) dorsal extension and dilatation of the third ventricle and (7) radial arrangement of the mesial cerebral sulci round the roof of the third ventricle and their extension through the zone usually occupied by the corpus callosum.

**Osteopoikilosis**—Nichols and Shifflett present a case of osteopoikilosis with pituitary disturbances, which has been observed for seventeen years. The symptoms led to a diagnosis of hypopituitarism and osteomas and numerous calcium deposits in bone and later of hypopituitarism (although roentgenograms of the skull showed a small, apparently normal, sella), hypothyroidism and osteopoikilosis. The onset of the patient's illness dates to early adolescence and has continued with few variations to the present. Roentgenograms show multiple osteochondromas with at least one lesion resembling a cyst, multiple disseminated areas of bone density characteristic of osteopoikilosis and apparently a definite and marked proliferative periostitis of the long bones and of the bones of the hands and feet, which at the present time is severe. The authors cannot make a definite statement regarding the type of pituitary involvement, but clinically the patient is suffering from hypopituitarism. They believe that the lesions of osteopoikilosis are within the spongy part of the bone and not exostoses originating in the cortex, and that the lesions are probably formed early in life and do not show progression either in number or size. They have no reason to infer that the exostoses and the periosteal proliferation are a result of extensions of the lesions described as osteopoikilosis. It would appear that they are of separate origin and that the periostitis and exostoses have been progressive while the areas within the spongiosa have been stationary. Since only bones formed in membrane have not been reported as involved it would seem logical to infer that osteopoikilosis in some way, is related to enchondral bone formation and that it results from an abnormal functional relationship between the osteoblastic and osteoclastic activity of cells during the period of growth but the histopathologic study made by Schmorl does not support this hypothesis. The inference of endochondral relationship also is supported by the fact that the diaphyses metaphyses and epiphyses are involved indicating that the process is associated with the period of growth and continues until the epiphyses are united. Bearing out the theory of Ledoux-Lebord, Chabaneix and Dessane that typhoid might be an etiologic factor, the authors' patient had had typhoid.

**Irradiation in Treatment of Psoriasis**—The method of Rosh in the roentgen treatment of psoriasis consists in the application of high voltage roentgen rays to the spine at those levels which correspond with the nerve supply to the affected

arcas of the body During the period of nine years he has treated forty six cases of generalized psoriasis Twenty-two were treated locally with superficial roentgen therapy, and twenty four, since 1928, were treated with high voltage roentgen therapy over the upper and lower thoracic spine In the latter cases the disease had existed for periods varying from six to twenty years None of the patients were hospitalized and they were able to follow their usual mode of life No effects attributable to the season of the year or climate were observed In most cases, following treatment, patients noticed at first an increase in itching, which was soon followed by a complete cessation of this symptom About three weeks after treatment it was noted that the color faded from the center of the affected areas, the scales became loosened and the surrounding infiltration in the skin was diminished In most cases a second series of treatments was given after a period of from six to eight weeks, during which time the majority of the areas were replaced by a brownish pigmentation Complete disappearance of the lesions occurred only in from three to six months after the administration of the last treatment In some persistent cases a year elapsed before the body was freed from the psoriasis

mal seizures In none of the ten patients studied was there evidence of a significant reduction in blood flow immediately preceding the onset of the seizures During severe convulsions there was a great increase in blood flow The changes that accompanied the seizures were the result rather than the cause of the seizures This evidence is against the theory of acute widespread anemia of the brain as an immediate cause of epileptic seizures

**Chordomas of the Cranium and the Spine**—Hass reviews a collected series of fifty-six chordomas and presents an example of a diffuse type of sphenoid-occipital chordoma, which produced symptoms because of involvement of various cranial nerves and of the brain stem The forward bulging of the epipharyngeal wall and the destruction of the basilar process of the occipital bone the anterior arch of the atlas and the tip of the dens epistrophei (as shown by roentgenograms) were fairly characteristic of a malignant chordoma Necropsy disclosed a tumor of relatively slow growth, which projected upward from the floor of the posterior fossa anterior to the foramen magnum The asymmetry of the skull and the anomalous vertebral artery lend strength to the theory that chordomas arise from rests of notochordal tissue displaced during the period of embryonic development

**Amount of Yellow Fever Virus Injected by Mosquito Bite**—Davis induced stegomyia mosquitoes infected with yellow fever virus to feed on new-born white mice The latter were killed immediately and extracts were made The extracts were injected in graded doses into rhesus monkeys In two experiments the titrations indicated that each mosquito injected at least 100 infective doses of virus during the act of feeding Mosquitoes from one lot, which was later used in a feeding experiment on a mouse, were titrated immediately following the infective blood meal and again after ten days A decrease in titer during the interval confirmed previous observations Yellow fever virus within the body of the mosquito appears not to increase but rather to diminish in quantity From a comparison of the amounts of virus in the whole insects and in the baby mouse after being fed on by mosquitoes from the same lot it is shown that probably about 1 per cent of the total virus content was injected at the time of biting

Anatomic Studies of Petrous Portion of Temporal Bone M C Myer  
son H Rubin and J G Gilbert New York—p 195

**Conservative Treatment of Petrositis**—Greenfield believes that in view of the fact that the discharge in petrositis does not originate in the tympanum but comes through the latter from the cells situated in the petrous pyramid, one should regard the presence of a profusely discharging ear in a case of petrositis as a most favorable therapeutic phenomenon He raises the question as to whether or not this perforating channel through the tympanum, spontaneously created, may not in some instances be sufficient to accomplish a cure without operative intervention If such is the case it may be advisable to postpone operation in patients in whom the aural discharge is profuse and in whom invasion of the intracranial structures does not appear imminent That spontaneous cure does take place is confirmed by the fact that the vast majority of patients with the so-called Gradenigo syndrome recover without operation Etiologically the two conditions are identical Anatomically they both represent involvement along certain groups of cells leading to the region of the apex of the petrous pyramid Pathologically, however, petrositis represents a more advanced, a more widespread and a more prolonged process It has a tendency to involve the deeper cellular structures rather than the superficial Therefore it is reasonable to expect that a similar termination may be effected in the cases of petrositis in which the aural discharge is profuse In many instances there is no reason why the drainage from this route may not be sufficient to cause spontaneous resolution The author reports two cases of petrositis in which no operation was performed because of the profuse aural discharge Both patients recovered

**Suprarenal Cortex Extract in Pyogenic Infections**—The experimental results in the treatment, with suprarenal cortex extract, of rabbits that had experimental maxillary sinusitis supplied sufficient grounds to Wenner and Conc to warrant the clinical use of cortical extract in pyogenic infections The extract used was prepared from whole beef adrenals according to the method of Zwerner, Agate and Sullivan The dosage varied from 2 to 7 cc given intramuscularly at intervals of two or more days The clinical results indicate that cortical

extract was effective in bringing about improvement. The extract tends to reduce the temperature when it is elevated. The patients feel better generally. They are less easily fatigued and can withstand operative procedures much better. No direct effect of the extract on the total and Schilling differential white cell counts could be determined. The blood picture improved with the clinical improvement of the patient. No significant changes were observed in patients presenting normal white cell counts. In cases of acute suppurative otitis with osseous involvement, cortical extract did not alter the necessity for surgical intervention. However, when cortical extract was used preoperatively the postoperative course was better. The extract was effective in infections limited to the mucous membrane of the nose, sinuses, larynx and nasopharynx and in cases of cellulitis. In patients with a well developed inflammatory reaction in the mucous membranes and in whom the resistance to infection was decidedly poor, the best results were obtained when the extract was given at intervals not longer than forty-eight hours. The response to pyogenic infections is probably due, in part, to an increased activity of the leukocytes. The opsonic power of the serum of both suprarenalectomized and normal animals is increased by injections of cortical extract (Blanchard). The authors confirmed Blanchard's observations on normal animals. Cortical extract injected intramuscularly increases the phagocytic activity of the leukocytes, but applied directly to suspensions of white cells it produces no noticeable change.

**Micro-Incineration as Aid in Diagnosis of Silicosis**—Irwin studied lung tissues from various types of pneumoconioses in order that the amount and relation of siliceous material present in the tissues to the histologic structure in which it was contained might be determined. This was accomplished by the micro-incineration of paraffin sections and the treatment of the ash with concentrated hydrochloric acid to remove the nonsiliceous material. By the use of serial sections the tissue ash can be related definitely to histologic structure. The lung tissues from ten gold miners, a coal miner, an iron miner, a Scotch stonecutter, a sandblaster, an abrasive soap worker and twelve rabbits with silicotic lesions produced by experimental dusting with silica were examined. In the human lungs the chemical assay for siliceous material was relatively high, and microscopically there was much nodular fibrosis, shown by micro-incineration to be associated with a high content of siliceous material. In most of the human cases there was an accompanying tuberculous infection. The ash content of the areas of fibrosis seen in this series of lungs was appar-

ently indicative of the pathogenesis of those lesions. The experimental lesions in the rabbit were not complicated by tuberculous infection. An examination of the incinerated acid treated sections of these lungs clearly demonstrated all areas which in the corresponding stained sections revealed fibrosis that had the appearance of being siliceous in origin. Areas of obvious tuberculous fibrosis presented an ash much less dense than the ash of siliceous nodules. This ash when treated with acid disappeared either entirely or partially, leaving a few scattered siliceous particles. The ash pattern of definite silicotic nodules is so typical and constant that the author infers that, if an ash is present, it represents a silicotic nodule, even if the corresponding area in the stained section has degenerated beyond recognition. If an area of ash does not contain any siliceous particles or contains only a few scattered siliceous particles, he also infers that such an ash represents an area of nonsiliceous fibrosis.

**Intravenous Injections of Animal Charcoal in Infections**—St Jacques has given more than 300 intravenous injections of animal charcoal in more than 150 patients having various infections (metrosalpingitis, puerperal infection, phlebitis, perineal laceration, lung infection, cholecystitis, furunculosis, gonorrheal arthritis, gonococcal epididymitis, nephrosis and nephrosis consecutive to puerperal infection), with not one untoward sequel. In some cases a slight rise of temperature occurred in the hour following the injection. The general circulation was unaffected in any way. Of the first 100 admissions only three were not cured of their infectious process. In the 200 later admissions the results were equally good. The preparation used was a 2 per cent suspension of animal charcoal in distilled water. The piston, syringe barrel and needle must be paraffined beforehand to prevent clogging by the particles of carbon. How charcoal acts is not known biologically, but it does stimulate phagocytosis as well as the endothelial cells of the spleen, liver and bone marrow.

**Chronicity of Rheumatic Fever**—Swift states that, while the symptoms and signs of rheumatic fever are often acute and severe, there occur in most cases additional features pointing to chronicity. The manifestations indicative of chronicity are the granulomatous nature of the typical pathologic lesions, a familial or inherited background, prolonged low grade fever and high pulse rate, an apparent instability of the heat regulating center, persisting or recurring arthritis, subcutaneous fibroid nodules, erythema marginatum and progressive and persistent valvulitis. Additional signs of chronicity may be obtained from such laboratory evidence as abnormal electrocardiograms, persisting leukocytosis and accelerated erythrocyte sedimentation rates. A long persisting tendency to recurrences or to new attacks of rheumatic fever is found in persons who have once suffered from the disease, and infections of the upper respiratory tract in such patients are much more likely to be followed by rheumatic fever than is the case in normal persons. Because chronicity in a disease or in suscep-

tibility to that disease indicates chronic measures for its treatment or prevention, it is necessary to be on the lookout in each case for manifestations indicating chronicity so that, when they occur, suitable prolonged therapy can be applied.

**Extrapleural Pneumolysis with Paraffin Pack**—Head believes that extrapleural pneumolysis with the paraffin pack

has a definite place in surgical treatment of pulmonary tuberculosis. The complications caused by the foreign body, which have deterred many from using it, have been largely eliminated. It has the advantages of being simpler, safer and less deforming than thoracoplasty and of making a strictly localized collapse of diseased lung without sacrificing vital capacity. It has increased the number of patients amenable to collapse therapy. Sauerbruch and Brauer have changed their ideas recently and now believe it the operation of choice for small apical cavities. It has been the author's experience that in cases in which the cavity does not extend lower than the fourth rib at the spine it is reasonably certain of producing the desired result. For larger cavities, thoracoplasty is more certain. When the indications are doubtful, one may be influenced by the consideration that the lesser operation may suffice and that, if it does not, a later thoracoplasty will be more certainly effective for the partial collapse already provided. He reports the results that he obtained in twenty-eight cases, which have been so satisfactory that at present, when confronted with large apical cavities, he uses a paraffin pack as a preliminary operation.

**Treatment of Osteomyelitis of Mandible.**—Miltner and Wolfe describe a method for treating the chronic stage of suppurative osteomyelitis of the mandible, which incorporates the following steps: 1. Removal of the necrotic outer plate of the mandible as soon as possible during the early chronic stage (i. e., twenty-one days after the onset). The necrotic bone is removed through a wide external approach and may be excised before it has separated spontaneously in the form of a sequestrum. In case of massive necrosis of both plates of the mandible, sequestrectomy is delayed until an involucrum has formed. 2. Removal of teeth over the area of osteomyelitis. These teeth are always loose and bathed in pus, and in most instances their pulp tissue is necrotic. 3. Exteriorization of the tooth sockets and partial resection of the alveolar process with complete closure of the gum margins to prevent further drainage of purulent material into the oral cavity. 4. Immobilization of the jaw. The authors present eight cases that were treated successfully by this method of management. The results have been encouraging and, they believe, superior to those which have been obtained by more conservative methods of treatment.

**Pneumonia Following Aspiration of Oil.**—Grayzel and DuMortier report two cases of pneumonia in children following the aspiration of oil or fat. Pinkerton studied the lesions produced experimentally in animals by intratracheal injections of various oils of animal, vegetable or mineral origin, and found that the resulting lesions varied with the type of oil used. The animal and mineral oils called forth a marked proliferative response on the part of the tissue, whereas practically no response resulted from the intratracheal injection of vegetable oils.

Late Tendon Suture. E I Lloyd.—p 165  
\*Second Attack of Acute Poliomyelitis. T Moore.—p 166

**Nonspecific Colitis and Deficiency Disorders.**—Hare points out the resemblances of colitis to a deficiency disorder and urges treatment with high vitamin diets and massive doses of iron or liver. The temporary increase in diarrhea or of other symptoms, which often follows at the outset, is no contraindication to continuing the treatment. Improvement in the intestinal symptoms may be slow, especially at the beginning of an acute relapse, and perseverance is required. It is urged that all local treatment and sigmoidoscopic examination should be avoided if possible, as the intestinal wall is highly susceptible to trauma. If colon lavage is continued, it may keep up the diarrhea and bleeding and cause apparent failure of other treatments.

**Second Attack of Acute Poliomyelitis.**—Moore reports a case of a second attack of acute poliomyelitis in which the observations indicate that the child had an attack of acute anterior poliomyelitis at an early age. This left him with some weakness of the lower limbs, but he was able to walk remarkably well in supports and lived as a normal boy until nearly 7 years of age. Then, following two rather indefinite febrile illnesses the muscular weakness became much more widespread. The weakness of the lower limbs increased in severity, and the hands and recti abdominis were affected in addition. In consequence the child was left in a helpless condition. While he has been in the hospital the condition of the limbs has not improved, but the recti abdominis are recovering slowly. The author believes that the explanation of this observation leaves no doubt that a second attack of acute anterior poliomyelitis had occurred.

**New Antigen of Bacillus Typhosus**—Felix and Pitt state that the factor present in virulent strains of Bacillus typhosus and responsible for their virulence and agglutinability is an antigen. This antigen is separate and distinct from the O and H antigens of B typhosus and renders the O antigen resistant to the action of the O antibody. The authors suggest the symbol  $V_1$  (referring to virulence) for this antigen and the corresponding antibody. The  $V_1$  antibody is demonstrable by agglutination and absorption tests, its in vitro titer is comparatively low. Active and passive immunization disclose the powerful protective action of the  $V_1$  antibody. The O antibody, which is known to exert bactericidal and opsonizing effects, also neutralizes the endotoxin of B typhosus, whereas the  $V_1$  and H antibodies are incapable of this action. The bearing of these facts on the theory and practice of antityphoid inoculation and of the serum therapy of typhoid is discussed.

**Paraldehyde by Rectum as Preliminary to General Anesthesia**—Whigham, in using paraldehyde as a preliminary to general anesthesia, gives 1 drachm (4 cc) of paraldehyde in 12 ounces (350 cc) of saline solution for every 14 pounds of weight (6.4 Kg). The solution is given at body temperature, slowly by the rectum from one and a half to two hours before operation. The patient lies on the left side with the buttocks slightly raised. The administration takes from thirty to forty minutes. In from twenty-five to forty-five minutes, the patient is sleeping. It has been the author's practice to continue anesthesia with gas and oxygen and, if necessary, a minimal amount of ether. When relaxation has been obtained, ether can usually be discontinued. Deoxygenation can be brought about at the end of the operation by the use of 5 or 10 per cent carbon dioxide-oxygen inhalations. The color of the patient is sometimes sallow after the paraldehyde has been given but improves quickly when gas and oxygen are administered and then usually remains good throughout the operation. On return to the ward the patient recovers consciousness in from one-half to two hours. A rectal washout is not necessary. Postanesthetic vomiting is slight or absent. Hiccups occur sometimes but are well controlled by the inhalation of 5 or 10 per cent carbon dioxide.

Necrosis Following Radium Treatment Preliminary Report H A McCoy—p 14  
X-Ray Necrosis E H Molesworth—p 16

**Necrosis Following Radium Treatment**—In an endeavor to estimate the factors that may contribute to the development of necrosis following radium treatment, McCoy studied the cases so affected. The factors appearing to contribute to the development of necrosis are unsuitable filtration and concen-

tration, large tumors adjacent to or involving the bone or the cartilage, radium buried in or near infected tissue and unfavorable sites for interstitial treatment. The author cites cases in which these contributing elements have been fairly constant. It appears that 0.5 mm of platinum should be the minimal filtration for the treatment of squamous cell epithelioma. In the treatment of lesions adjacent to or involving the bone, it is probable that an increase of filtration to 1 mm of platinum would be desirable if interstitial treatment should be contemplated. A surface technique, in the form of molds, appears to possess advantages over interstitial methods in lesions involving the bone or the cartilage. An attempt should be made to eliminate infection before radium treatment is commenced. Concurrent syphilis should be treated before and during the progress of radium treatment. It appears that in certain lesions (particularly those involving the bone) necrosis is inevitable if radium treatment is to be effective in destroying the neoplasm.

**Hematopoietic Activity of Human Liver in Pernicious Anemia**—Wilkinson and Klein examined extracts of the liver from ten normal and abnormal human subjects for their hematopoietic potencies as judged by clinical trial in cases of pernicious anemia. The results show definitely that the antianemic 'liver principle' is present in normal human liver and in treated cases of pernicious anemia in active remission but is absent from the liver in untreated cases of pernicious anemia. The liver from a patient with polycythemia rubra was found to be more potent than normal human or calf's liver. These results show that the liver acts as a storehouse for an anti-anemic factor (the 'liver active principle'), which is produced in the stomach as a result of enzyme action between hemopoietin (the 'stomach active principle') and an unknown constituent of a normal diet.

**High Oxygen Atmospheres and Chronic Cardiac Insufficiency**—Richards and Barach observed two normal men and twenty-eight patients suffering from cardiac insufficiency who resided in atmospheres of from 40 to 50 per cent of oxygen for continuous periods ranging in length from five days to seven months. Studies have been made in these subjects of the effects of high oxygen atmospheres on circulatory and pulmonary functions and in certain instances on their water and electrolyte balances. The study showed that prolonged, continuous oxygen therapy will frequently restore to limited compensation a patient suffering from arteriosclerotic heart disease and insufficiency (not complicated by chronic nephritis), that it may increase the comfort and relieve dyspnea in a case of decompensated rheumatic heart failure and that it will usually relieve symptoms in chronic pulmonary fibrosis with cardiorespiratory failure and may, if sufficiently prolonged, restore such a person to limited ambulatory activity. The tissue oxygen deficit is probably the best criterion of the need for increased oxygen in the respired air. Arterial oxygen saturation is not a certain index of oxygen want, but, if the arterial oxygen saturation is depressed below normal, oxygen therapy is definitely indicated. Symptoms of oxygen want exist even when arterial oxygen saturation is within normal

limits may be relieved when the patient is placed in an atmosphere of 50 per cent oxygen. Arterial oxygen saturation in such cases usually rises to 97 per cent or more. Clinical cyanosis is a poor criterion of the degree of oxygen want. Marked arterial oxygen unsaturation may exist when clinically cyanosis appears slight. Conversely, deep cutaneous cyanosis may be present with normal arterial oxygen saturation and without general symptoms of oxygen want. In such cases, response to oxygen therapy may be poor. In chronic cardiac or pulmonary insufficiency dyspnea, restlessness, cardiac pain, arterial oxygen unsaturation, cyanosis and cough are the symptoms and signs, in the order of their importance, that establish the need for increased oxygen in the respired air. The two normal subjects, residing for a week in 45 per cent oxygen, showed a fall in pulse rate, a slight rise in the carbon dioxide blood levels, and no appreciable change in respiratory metabolism, in cardiac output or in the excretion of electrolytes or water.

Antitetanic Vaccination L Bazy—p 1171

**Myxoleukocytic and Chlorhydropeptic Reactions of Stomach**—Loeper and Fau investigated the comparative mucoleukocytic stomach secretion and the peptic hydrochloride secretion. As a result of numerous examinations, they concluded that the normal empty stomach contains no mucus. The pathologic empty stomach contains mucus only when it is hypochlorhydric. Myxogenic foods are those which do not stimulate the hydrochloride secretion. Cancer of the stomach produces mucus, while ulcer does not produce it. The same antagonism exists between the simple hypochlorhydrias and the hyperchlorhydrias, the first being myxocytic and the second not. The antagonism is not so evident or constant in the different kinds of gastritis, and especially in alcoholic gastritis, doubtless because of the different stimulation of the elements of the lining. The presence or abundance of mucus in hyperchlorhydria or its absence in hypochlorhydria is a sign of diffuse gastric lesion, an inflammatory process rather than neoplasm or ulcer. Drugs stimulating the vagus decrease the secretion of mucus, as inhibitors of the vagus increase it. Gastric leukopedesis parallels the production of mucus and inversely the chlorhydropeptic secretion. Myxogenic foods and drugs can be used in case of heartburn and especially in hyperchlorhydric gastritis or ulcer. Atropine, which paralyzes the vagus, has simultaneously an antispasmodic, antichlorhydric, leukopedic and myxorrhic action, and this explains its quieting and reparative action in ulcer and hyperchlorhydria.

- \*Some Biologic Modifications in Gold Fever Therapy of Psychoses Their Prognostic Value H Claude J Duhleau and Kerfridun—p 1209

**Gold-Fever Therapy of Psychoses**—Claude and his collaborators describe the results of treating patients suffering from dementia praecox with injections of sulphur and gold. The technique involved the injection of sulphurated oil in progressively increasing doses of from 1 to 10 cc at intervals of five or six days. In the intervals a soluble or insoluble gold salt was injected intravenously or intramuscularly in increasing doses, the total dose being generally about 0.15 or 0.16 Gm of the metal. In cases responding unfavorably a second series of the same kind was employed after several weeks rest. In a series of twenty cases treated in this manner, nine apparent remissions or cures were obtained. The febrile reaction varied,

but an average moderate febrile reaction occurred following most of the injections. One of the most important biologic modifications was the variation in intensity of the flocculation with resorcinol. This appeared to be partly dependent on the degree of fever during the day of examination. In any case an elevated index seemed to be of favorable prognostic import. The erythrocyte sedimentation appeared to give curves generally paralleling the curve of flocculation. Fever therapy also caused a leukocytic reaction with neutrophilia, but this did not affect the general prognosis. There is some possibility of the treatment activating a local pleural or pulmonary tuberculosis, which must be considered both before and after the treatment, but even when this occurs it is usually not a serious complication.

\*Febricula and Thyroid Function G Macchioro—p 127  
Intratracheal Injections in Diagnosis and Therapy Various Techniques and Recent Transnasal Method M Mazzetti—p 136

**Febricula and Thyroid Function**—Macchioro states that slight attacks of fever, persisting for long periods and resisting all treatments find their origin in a disharmony between the endocrine and the sympathetic systems and in increased thyroid function. These attacks of fever occur infrequently. In a large amount of clinical material the author found only five cases in which the lack of equilibrium was regarded as the causal factor of the thermic disturbance. It is difficult to decide whether slight fever during hyperthyreosis is due to increased thyroid function or to toxemia of incipient tuberculosis. Of nine patients presenting slight tuberculous manifestations and temperatures of approximately 37°C (98.6°F), five were given intravenous injections containing 5 cc of a 2 per cent solution of sodium fluoride every other day. Five cases showed forms of glandular localization, while four showed parenchymal changes in the lung. The fever curve in all patients descended after treatment but never came to apyrexia. If sodium fluoride does not make the fever disappear, it demonstrates nevertheless to what degree the thyroid participates in its occurrence.

Autohemolysis Due to Cold in Dementia Paralytica G Rabboni—p 470  
\*Parathyroids and Osteitis Fibrosa Cystica L Ficacci—p 489

**Parathyroids and Osteitis Fibrosa Cystica**—Ficacci describes three cases of recurrent polyarthritis presenting local lesions and multiple cysts the size of an average coin in the lower metaphyses. In a fourth case, of hypertrophic osteoarthritis with effusion into the knee joint and into the tibioastragalic articulations, the lesion, cystic in type was found in the right internal malleolus. In one case the lesion gradually disappeared after several months of treatment. A biopsy made in one case showed the cystic reabsorption of the bone and the fibrous transformation of the marrow as in osteitis fibrosa cystica. The author found many zones of rarefaction in the intercondyloid regions of a patient having arthritis of the knee and many such zones in the fibula of a patient who had had typhoid a year before with foci of periostitis on the right tibia and on the first left middle phalanx. The diagnosis in this case was confirmed by the reaction of Widal and the isolation of the typhoid bacillus from the biopsy material of the focus of tibial periostitis. The calcemia remained normal in the first four cases, while it varied from 0.015 to 0.018 Gm per hundred cubic centimeters of serum in the last two. An epiphyseal alteration of vacuolar aspect was present in two cases of hemophilic arthropathy. The author maintains that in these cases this alteration is due to the fundamental lesion and that the parathyroids participate in the process only as secondary factors producing the changes in the calcium metabolism. He states that circumscribed fibrous osteitis must be distinguished from von Recklinghausen's disease, the result of primary hyperparathyroidism.

- Notes and
- Behavior of Glycemia Due to Introduction of Stomach Tube—Cozzutti describes changes in the glycemia occasioned by introducing any substance in fifteen patients suffering from various diseases. He found that the introduction of a duodenal catheter frequently lowers the glycemia and that the passage of a stomach tube likewise has the same effect and almost to the same degree. He interprets the phenomenon on the basis of the existence of a humoral reflex (secretin) in addition to the mechanical reflex (duodeno-insular). The author states that there is a close functional relation between the stomach and the pancreas, this relation involves not only the external secretion of the pancreas but its endocrine activity as well. The pancreas, in addition to the response to nervous stimuli, was found to react to gastric stimuli of a probable mechanical humoral type by both endocrine and exocrine function. The digestive tract is not only served by the process of digestion but is likewise assisted by the activity of its accessory glands participating in the endocrine activity. There is a close functional circulation between the insular pancreas and the digestive tube. The author has demonstrated the possibility of eliciting a pancreatico-insular response through a mechanical-humoral stimulus, and the influence of the gastric juice on the insulin confirms it. The acinous and insular pancreatic secretions are mutually dependent in their functional activity. In the pathology of the digestive tract the secondary changes in the external pancreatic secretion due to the absence or the abnormality of gastro-intestinal stimuli must be taken into consideration as well as those of the internal pancreatic secretion. In the pathology of the insular pancreas there is always a secondary alteration of the gastro-intestinal function.

- Treatment of Pulmonary Tuberculosis—Girones obtained partial immobilization of the left side of the thorax of a tuberculous patient by means of a plaster-of-paris cast provided with a large window over the healthy side. The patient had a history of a previous inflammatory condition and pulmonary adhesions accompanied by hemoptysis and severe diarrhoea. Roentgen examination demonstrated a cavity 6 by 38 cm, in the left upper lobe below the clavicle. The right lung appeared normal. The patient's condition did not improve during the first weeks of observation. The expectoration increased to 55 cc while the erythrocyte sedimentation speed was high. Another roentgen examination showed the cavity to have increased to 68 by 45 cm. The author placed a plaster-of-paris cast over the thorax and after two days cut a large window on the right side. At the end of a month the cavity was reduced to half its former amount and the expectoration was reduced to 31 and the weight had increased 4½ pounds (2 Kg). The cavity had retracted considerably. The pulmonary tissue in the region of the anterior aspect of the second rib showed marked retraction on the roentgenogram. Another cast was applied at a later date. The therapeutic result was satisfactory and warranted further application of casts to patients having unilateral and bilateral cavities in which pleural adhesions made pneumothorax impossible.

- Nonspecific Inflammatory Tumors of Large Intestine—The clinical picture of a nonspecific inflammatory tumor of the large intestine, according to Anschütz, falls into one of three groups. 1 Tumors operated on as real or specific tumors. 2 Cases considered appendicitis or appendiceal abscess. 3 Cases recognized from history and clinical behavior as nonspecific inflammatory tumors. Their gross appearance at operation resembles closely that of carcinoma or tuberculosis. Microscopic studies reveal the typical picture of a chronic inflammatory process. Among the etiologic factors one must consider foreign bodies, circulatory disturbances, parasites, appendicitis, diverticulitis, all forms of colitis, typhus and dysentery. The particular pathogenesis is due to an attenuated infection on the one hand, and an impaired local resistance on the other. In the diagnosis one must always think of the possibility of carcinoma. The treatment should always be radical, with particular regard for the inflammatory nature of the process.
- Significance for Blood Transfusion of Isohemo-Agglutination Subgroups A<sub>1</sub> and A—In his study of determination of blood groups Blinov found that factor A does not represent a definitely separate group but that it may exist in two variants designated by A<sub>1</sub> and A. As a result, each of the groups A and AB is divided into two subgroups A<sub>1</sub> and A, A<sub>1</sub>B and AB. These groups are recognized qualitatively through definite serologic characteristics. The difference in the properties of these subgroups explains the so called exceptions in the classic four-group scheme and the transitions of one group into another as described by various authors. In the author's experience A<sub>1</sub> is three times as frequent as A, while A<sub>1</sub>B is about as frequent as A.B. A<sub>1</sub> and A<sub>2</sub> are hereditary characteristics. They are transmitted to the offspring according to the mendelian law, A<sub>1</sub> being the dominant and A the recessive factor. This fact may be of considerable value in medicolegal questions. In the preparation of the standard serum of group A, one should use the blood of only the subgroup A<sub>1</sub>. The standard erythrocytes must likewise be taken from the subgroup A<sub>1</sub>. There were no cases of death in the author's material from the use of incompatible subgroups, although severe reactions were observed.
- Bile Peritonitis Without Visible Perforation—The finding at the time of operation of bile in the peritoneal cavity without a visible perforation of the gallbladder or the bile ducts suggests, according to Melchior, three possibilities. 1 Actual absence of a perforation. 2 A perforation that has taken place but became sealed and could not be detected as such. 3 An existing perforation not noticed because of the difficulty of exposure, its true character being revealed, as a rule, at necropsy. A distinction, therefore, must be made between the clinical concept of bile peritonitis without visible perforation and its narrower anatomopathologic concept. To the latter group belong the cases that are the result of a simultaneous effect of an infection and stasis of the walls of the gallbladder and of the biliary tracts. Under such conditions the bile may diffuse through the gallbladder wall without the existence of an actual perforation. There is clinical and experimental proof that regurgitation of the pancreatic secretion into the bile tract may likewise bring about an abnormal transudation of bile. Under certain pathologic conditions, such as obstruction of the cystic or the common duct and acute inflammation

of the wall of the gallbladder, the latter was seen by the author and other surgeons to "sweat" bile. A laparotomy sponge applied to the wall of the gallbladder with moderate pressure becomes tinged with bile. The author reports two cases in both of which there was found at operation a severe bile peritonitis without visible perforation. Both were instances of chronic choledocholithiasis with acutely supervening partial necrosis of the liver. Transfusion of bile took place from massive foci of liver necrosis. The author believes that, besides the element of infection, the toxic effect of free bile within the peritoneal cavity plays an important part in the fatal outcome. This toxic effect is due to the rapid absorption of the bile salts, which are toxic for the organism. They become bound up with the red cells and with the muscle cells, among others those of the heart. In the presence of a considerable effusion, lethal concentration may be reached in twenty-four hours. The clinical picture of cholemic poisoning is characterized by pronounced adynamia, cardiac weakness and vasomotor paralysis.

\*Oral Bismuth Poisoning S Serefis—p 968

**Two Forms of Gastritis**—Korbach describes a case of membranous and a case of aphthous gastritis. Both had ulcer-like aspects, the membranous gastritis presenting the symptoms of a duodenal ulcer, the aphthous gastritis those of a ventricular ulcer. In the first case gastroscopy revealed an inflamed, red mucous membrane that was strewn with glistening white crystal shaped formations of mucus. Following irrigation treatment, most of the exudations of white mucus disappeared, but they persisted in the region of Waldeyer's stomach tract and became flatter and membrane-like. In the patient with aphthous gastritis, gastroscopy revealed in the lower portion of the body of the stomach a large number of lentil-sized aphthous tumors, most of which were circular, oval or bean shaped. Some appeared slightly lacerated. In the region of the cardiac sphincter there were small erosions. Ten days later a control gastroscopy after irrigation treatment disclosed in the region of the angle several already deepened ulcers, the size of pepper grains. The formerly observed ulcers on the posterior wall had largely disappeared. Because of the danger of a niche forming ulcer, feeding with the jejunal tube was instituted. But a new gastroscopy several weeks later revealed a new exacerbation of the aphthous gastritis, in that a large number of small erosions covered the reddened mucous membrane, particularly around the cardiac sphincter. The author states that he observed such aphthoid ulcers also in several other patients. They sometimes persisted for months and even led to niche formation. However, these ulcers with rather large niches as a rule yield within a comparatively short time to treatment with the jejunal tube or even to a simple milk gruel diet and rest in bed. Intramuscular injections of blood and other measures are helpful. Why these hemorrhagic erosions, which are probably also responsible for the majority of gastric hemorrhages, occur only in some of the gastritides is a histologic problem, the solution of which has been begun by O Muller's capillaroscopic studies.

**Oral Bismuth Poisoning**—A review of the literature convinced Serefis that opinions differ widely about the mechanism of oral bismuth poisoning. Many investigators nevertheless agree that a strong acid reaction of the gastric juice is essential. Some believe that an excess of lactic acid is necessary, while others consider an increased hydrochloric acid content essential. The author based his own tests on the intestinal resorption of bismuth on the assumption that probably only the bismuth salts that are in solution become absorbed. Accordingly he investigated the requirements for the solubility of bismuth in the gastro-intestinal tract and studied the behavior of bismuth subnitrate in contact with the acids of the gastric juice *in vitro* as well as in the animal experiment. Tests with hydrochloric acid and with lactic acid revealed that the presence of lactic acid is a promoting factor but not an absolutely essen-

tial one in the solution of bismuth in the stomach. Other test tube experiments revealed that bismuth subnitrate is changed into bismuth chloride not only by free hydrochloric acid but also by the chlorides of the mineral salts, such as sodium chloride. Since the latter is taken in with the food, bismuth chloride can be formed even in the absence of hydrochloric acid. For the resorption of bismuth chloride it is important that it have a tendency to form complex compounds, such as with organic acids and their salts, with polyvalent alcohols and with various types of sugar. If, for instance, sodium citrate or sodium lactate is added to the acid bismuth chloride solution, it is possible to dilute this solution greatly without precipitation taking place. If in addition to that a polyvalent alcohol or a sugar is added, the solution can be rendered alkaline without causing precipitation. The bismuth reaches the small intestine in the compound form, and here resorption takes place. After discussing factors that play a part in the resorption in the small intestine, the author states that his test tube experiments were corroborated by animal experiments. He concludes that, since the resorption requirements of orally administered bismuth are now known, there remains only the problem of the correct dosage to permit the oral bismuth therapy of syphilis. His studies on the dosage problem will be reported soon.

**Cod Liver Oil Salve Treatment of Fresh Wounds and Burns**—In a bacteriologic study of various fats and oils, Lohr found that they are usually bacteria free even when not sterilized. Bacteria ordinarily encountered in infected wounds, streptococci, staphylococci and *Bacillus coli*, perish when introduced into cod liver oil. It has not been determined whether they die because the cod liver oil contains no nourishment for them or because of the surface tension of the oil. It was further demonstrated that large amounts of the cod liver oil used in the treatment of extensive wounds did not cause toxic manifestations of any kind. The oil was used in combination with indifferent substances to give it the consistency of a paste. The oil in this salve permeates the tissues and causes a rapid liquefaction of the necrotic tissues, followed by a powerful stimulation of the growth, which affects all tissues, including the epithelium. Large areas fill with granulation tissue and these become covered with regenerated epithelium. The author did not resort once to skin transplantation during the last three and one-half years in which he has used this form of treatment. The inhibiting effect on the bacterial flora of wounds was likewise striking. The technic of treatment of fresh industrial wounds consists of the usual toilet of the wound with omission of suturing. A thick layer of the cod liver oil salve is laid on the wound surfaces and in the case of an extremity a plaster-of-paris cast is applied over it. The cast is removed at the end of fourteen days and the lesion is usually found to be healed. This treatment is not applicable to wounds badly soiled with earth or highly infected, to paronychia or to gas bacillus infections. Such wounds are treated by excision and application of disinfecting agents. The cod liver oil treatment is resorted to only after the infection has been overcome in order to obtain good regeneration. On the other hand, the treatment finds its application in chronic wounds, even if infected. Its effect is particularly striking in burns. The author has treated with this method 122 cases of second and

third degree burns The treatment was no more effective in preventing the early fatalities of burns than any other method. However, the late fatalities due to secondary infection were markedly reduced, more so than with the tannic acid method, because it is applicable in difficult localizations, such as the face, the buttocks and the anus. The regenerative effect on the epithelium was seen most strikingly in burns. Thus the author observed epithelization of an area of third degree burn 45 cm square. The change of dressings is not painful, because the salve is removed in thick layers leaving the new granulation tissue intact. The author is of the opinion that the effects enumerated are due to the vitamin A and D content of the cod liver oil.

the cells, while in case of melanotic pigmentation the pigment is within the cells, and the intercellular spaces are free from it. The differentiation of silver and melanotic pigment is possible also by means of histochemical methods.

Functional Diagnosis of Diseases of Pancreas by Determination of Lipase and Amylase Content of Blood A A Zelikson — p 908

**Functional Diagnosis of Diseases of the Pancreas** — Zelikson found in a study of thirty-five cases that determination of ferments obtained with the aid of the Einhorn duodenal tube is entirely unreliable. Determination of amylase in the urine in thirty-three cases likewise proved to be of little diagnostic value. The author examined the lipase and amylase blood content in ninety-two cases. Determination of blood lipase after the method of Rhon depends on the fact that in patients with pancreatic disease the atoxyl fails to activate the lipase, while in the normal organism its effect is to activate the ferment. The reliability of the Rhon test for lipase and of three cases either at an operation or at necropsy. In a group of eight cases with proved pancreatic lesions there were four instances of a negative Rhon test. The study of blood amylase led the author to believe that the latter reflects not so much the condition of the pancreatic function as the patient's general fermentative ability. The author concludes that the reaction of Rhon is comparatively of the greatest value in functional diagnosis of pancreatic disease, particularly in the early stages. The reaction may be negative even in extensive involvement of the organ shortly before death. It may be negative in cystic disease of the pancreas. In view of the simplicity of the technique and apparatus, the author feels that the test should be made a part of the general clinical routine. The test should be applied not only in suspected cases of primary pancreatic lesion but also in cases in which the pancreas may be secondarily involved. Determination of blood amylase is of significance only in the presence of a positive Rhon test.

Surgical Treatment of Pain A L Polenov and T S Babchin — p 177

**Surgical Treatment of Pain** — Polenov and Babchin report forty cases in which chordotomy was performed for intractable pain of inoperable cancer or for meningoradiculitis and in which they have obtained either a complete alleviation of pain or at least a marked diminution. The advantages of the operation are that 1 It is capable of producing anesthesia of a large area, insignificant traumatism consisting of a laminectomy of only two vertebrae and of an incision into the spinal cord for a depth of 3 mm. 2 It destroys pain and temperature sense but leaves undisturbed all forms of deep sensibility, muscle tone and function, reflexes and trophic influences. 3 It is applicable to the lesions of the spinal cord itself. A bilateral chordotomy is justified for the relief of pain in a bilateral lesion. Among the disadvantages the authors point out the possibility of injury to the pyramidal tract with paresis of the lower extremity and recurrence of pain due to insufficient sectioning. Among the general causes of failure to relieve pain by the surgical methods the authors stress insufficient knowledge of the pathological ways of pains and their individual variations in peripheral

**Effect of Cod Liver Oil on Pyogenic Bacteria** — Lohr and Treusch point out that theoretically it would be better to use the natural cod liver oil in the treatment of wounds, because that would bring the greatest possible amount of vitamins A and D in direct contact with the wound tissues, constituting a parenteral vitamin therapy. Bacteriologic tests proved that cod liver oil is free from bacteria and that organisms introduced into it perish. This is true for the ordinary pyogenic bacteria and for *Bacillus tuberculosis*. However, the use of pure cod liver oil in bone cavities and other situations is not advantageous because it dries rapidly and because a good deal of it is lost. It was therefore necessary to combine it with some inert substance that would not affect the rather sensitive vitamins A and D. The authors found petrolatum suitable for the purpose. As a result of their extensive clinical studies they conclude that cod liver oil therapy has a definite curative effect. The treatment should be looked on as a means of increasing the defense powers of the tissues. The addition of petrolatum reduces the bactericidal power of cod liver oil and calls for a careful examination of it as regards its sterility.

**Local Argyrosis of Uterine Cervix** — Dworzak states that general argyrosis is today a rare disorder because of greater precaution in the therapeutic application of the silver salts. However, local argyrosis resulting from the application of silver solutions is still a comparatively frequent occurrence. The dermatologist is familiar with the condition, but, if the literature is any indication, the gynecologist has not given it attention. Since silver solutions are employed by the gynecologist, the occasional occurrence of a local argyrosis of the vagina and the cervix seems likely. The author relates the clinical history of a woman, aged 39, whose cervix had been repeatedly treated with silver solutions. The later removal of a cervical polyp revealed a dark brown pigmentation. The pigment gave no iron reaction but other tests revealed that the pigmentation consisted of silver. This observation induced the author to investigate the problem further. He found brownish pigmentations on the vaginal mucous membrane of a number of women whose cervix had been treated with silver solutions. After citing several experiments, he compares the genuine melanin pigmentations that have been observed on the cervix and the cervical polyps with the dark pigmentations caused by deposits of silver in the tissues. He emphasizes that the silver granules are found primarily in the intercellular spaces, rarely within

nerves and in the spinal cord, mistakes in operative technic, such as the choice of the wrong place or level or incomplete interruption, the individual regenerative power of the peripheral nerves, and the existence of collateral innervation

Experimental Investigations on Problems Regarding Sexual Hormones with Especial Regard to Feminizing Substances H Seemann —p 310

Studies on Relation of Simple Glaucoma to Internal Secretion V Larsen —p 318

**Chronic Peritonitis Incapsulans**—Hindse-Nielsen presents the case of a girl, aged 15, of tuberculous family, who for seven or eight months had periodic attacks of ileus, which always yielded to atropine. Laparotomy, done under the diagnosis of probable mesenteric cyst, revealed a peritonitis incapsulans containing about 1 meter of ileum. Ileocecal resection was done, the patient has been followed for three years and continues well. The author reviews peritonitis incapsulans on the basis of fifty cases from the literature. He says that it occurs most often in the second and third decades of life, in which the proportion between men and women is 93:142, in the entire material the proportion is 20:30. He regards the disorder as clinically and pathophysiologically a substrate for several different disorders: it is a localized, adhesive, fibrohyaline or fibrous peritonitis, which represents an organized remnant exudate after a diffuse peritonitis has originated about a focus in the intestine or mesentery, or is a link in a more diffuse, chronic serositis. Etiologically the disorder is related to specific infections (tuberculosis, syphilis) and nonspecific infections (pneumococcal infections) and also to traumas and cancer. The symptoms are constipation, pain, recurring subileus and palpable abdominal tumor. Treatment consists in laparotomy, with dissection or extirpation of the capsule, otherwise anastomosis around the pseudocyst or resection, if it is evident that enough intestine will be left. In cases in which for some reason removal of the capsule is not attempted or has been abandoned, roentgen treatment may be tried. Atropine is recommended in attacks of pain.

Has Mammalian Organism in Recent Years Lost Its Ability by Non-specific Action to Increase Its Defense Against Toxin Poisoning and Attack of Pathogenic Microbes? L E Walbum —p 793

\*Investigations on Influence of Hormone of Posterior Lobe of Pituitary Body on Urea Clearance T Bjerling —p 808

**Influence of Hormone of Posterior Pituitary on Urea Clearance**—Bjerling states that after the injection of this hormone the creatinine and the urea clearance were reduced, the urea clearance relatively more, both in patients with sound kidneys and in those having nephritis, but especially in the former. The hormone decreases the filtration of urea and promotes resorption back into the tubuli. This increased resorption occurs independent of changes in the creatinine concentration index, and the ability of the tubuli actively to resorb is assumed to be changed after injection of the hormone.

Application of Respirator in Acute Anterior Poliomyelitis F Wulff —p 814

Distribution and Application of Poliomyelitis Convalescent Serum (P C S) State Serum Institute —p 817

**Studies on Preparalytic Stage of Poliomyelitis**—Of Baastrup's 120 cases, 105 (87 per cent) presented pathologic spinal fluid, ninety-one (76 per cent) increased globulin, eighty (67 per cent) pleocytosis and sixty (50 per cent) increased

albumin. Meningeal symptoms were present in all cases. He asserts that for the clinical diagnosis of preparalytic poliomyelitis the presence of three cardinal symptoms is necessary: spinal stiffness with pain on bending forward, typical appearance and fever, spinal rigidity being the most decisive. With regard to the differential diagnosis, the meningeal symptoms are the exception in influenza, while they are the rule without exception in preparalytic poliomyelitis. In cases of preparalytic poliomyelitis showing stiffness of the neck and milder positive Kernig-Brudzinski symptoms, and especially in the rare cases showing, in addition, somewhat dulled sensory apparatus and suggestion of spasms, clinical differentiation between encephalitis and preparalytic poliomyelitis is hardly possible on a single examination, immediate clinical differential diagnosis between preparalytic poliomyelitis and tuberculous meningitis may also be impossible if tubercle bacilli in the spinal fluid or certain tuberculous manifestations elsewhere cannot be established. In these cases the author advises the administration of convalescent serum on suspicion, if sufficient serum is available. Human convalescent serum was given in twenty-two cases in five cases of the paralytic stage, because of the grave general condition, and in seventeen moderately grave or grave cases of the preparalytic stage. The serum had no prohibitive effect in the three preparalytic cases in which tremor, ataxia and patellar reflexes were already present on administration, showing insult to the spinal cord, the other fourteen cases remained aparalytic. Marked improvement of the general condition was seen in sixteen cases. Administration of convalescent serum is advised only in the preparalytic stage, preferably at the beginning of the first twenty-four hours, and only when there are no symptoms of the spinal cord, intravenously (intramuscularly if intravenous injection is unsuccessful), in a single large dose, the minimum dosage being approximately from 20 to 30 cc for children about 1 year old and increasing according to age and weight to from 50 to 70 cc for adults.

**Recognition of Aparalytic Cases of Poliomyelitis**—Nissen classifies poliomyelitis into three forms, the fulminating, the cases with slow course and accentuation of the symptoms until paresis occurs including the cases with diphasic course, and the meningeal aparalytic form, with or without slight disturbances of reflex. He tabulates his cases: thirty-three paralytic and twenty-one aparalytic, from the summer of 1933 to the spring of 1934. The aparalytic cases were diagnosed as poliomyelitis on the basis of simultaneous occurrence of paralysis cases, occurrence of aparalytic and paralytic cases among brothers and sisters, assumed contact infection, and results of examination of spinal fluid and other laboratory investigations. While the paralytic cases mainly appeared in the first four years of life, the aparalytic cases dominated in the school age.

**Infantile Paralysis Epidemic in Sukkertoppen, Greenland**—Hrolv reports eighty-three manifest cases and a large number of abortive cases of acute anterior poliomyelitis of an epidemic in the summer of 1932. He concludes that immunity is conferred on all who have had the disease including abortive cases, no one living during the epidemic of 1914 was affected in 1932. There is violent and rapid spread of the disease, causing high morbidity, mostly abortive, and epidemics of short duration. The virus lives for years, leading to epidemics when favorable conditions arise, perhaps with increase of virulence on repeated transplantation from person to person. The danger of infection from manifest patients is slight. The infection spreads from well carriers, from the abortive cases and from patients in the incubation stage, presumably by droplet infection. The incubation period varies from one to from fourteen to twenty days. In the main, the shorter the incubation period the graver the disorder, and the longer the incubation period, the milder the disorder. Infantile paralysis is also endemic in South Greenland.

### CORRECTION

**Transverse Fractures of Neck of Radius**—In the abstract of the article by Patterson in THE JOURNAL, September 1, page 713, the first line should read 'Patterson describes a closed method of reduction' instead of 'operative removal'.

## THE CANCER PROBLEM TODAY

CHAIRMAN'S ADDRESS

WILLIAM CARPENTER MACCARTY, M.D.  
ROCHESTER, MINN.

From time to time for many centuries it has been the duty of observers to appraise the status of the problem of cancer and point out means of promoting its solution. Each stresses quite naturally the field in which he has been most active. It would be unusual to find any one who could do justice to all phases with perfect equanimity. I shall not take the time or detract from my specific purpose by presenting a historical review of existing knowledge, this has been done frequently and is to be found at easily available sources.

The cancer problem, as I see it, has five distinct parts, which I shall enumerate in their probable order of practical importance.

1 The recognition or diagnosis of this disease or complex of diseases by laymen, general physicians, general pathologists, surgical pathologists, surgeons, and teachers of medicine. Each has its own limitations.

2 The statistical frequency of the disease and its relation to human welfare and possibly to that of other forms of life.

3 The application of empirical methods of treatment, there being, as yet, no known infallible specific method.

4 The education of active members of the medical profession, medical students and all those who are or might be affected by this disease.

5 Endowment and execution of pure scientific experimental research which has for its function the study of the biologic nature of the disease.

For fear of being considered unappreciative of pure experimental research, which I have placed fifth in importance, may I say that I have participated in experimental research most of my life and am somewhat familiar with what is being done throughout the civilized world. There should be nothing but the highest praise for the experimenters, their work and their financial benefactors. They have contributed much to general knowledge, their activities involve diverse, painstaking and time-consuming methods of approach. I know of no branch of scientific knowledge or procedure that has not contributed positively or negatively to the study of this problem.

The search for the distribution of cancer in all forms of life has revealed much to suggest that it is a biologic phenomenon not dependent on any single specific

factor and that it is a cellular defensive reaction to a local abnormal environment which is not efficiently eliminated by multicellular organization. The wide range of the disease suggests further that the many very different specific causes vary perhaps with species, habits, geography, organs, tissues and portals of entry. Although possibly quite different, they produce tissue destruction with consequent attempts at regeneration, during the partial failure of which the cells take on a migratory and individualistic phase which eventually destroys the whole organism of which they have been a part. This is of course not an unheard of phenomenon of life and is not characteristic alone of cells but of much larger units such as human beings.

The pure experimentalists have confirmed the old empirical ideas that chronic irritation and heredity play parts although the mechanism of heredity may still be under discussion. Despite this progress, a specific cause of human cancer has not been discovered, no means of producing immunity has been established, there is no means of making the diagnosis early other than with a microscope, there is no specific method of treatment and no immediate practical means of preventing the disease through knowledge of genetics. In my opinion one of their greatest functions is censorship of the many "cancer cures" that too readily gain publicity, I have seen excellent physicians and surgeons become prematurely enthusiastic and sincerely advocate immature spectacular ideas relative to the cause, diagnosis and treatment of cancer.

Despite the things the pure researchers have not done I still believe their experiments should be continued, increased, and even more abundantly endowed, they will undoubtedly discover the true biologic nature of this disease, which is now one of the greatest destroyers of mankind.

As to the recognition or diagnosis of cancer. The layman cannot be expected to differentiate it from other diseases but he can and should be taught the specific things that might arouse enough suspicion to send him to a properly trained physician. The general physician also cannot be expected to recognize it in its early stages as he is being educated today. The general pathologist who spends his time performing autopsies on those dead of cancer cannot be expected to recognize the early stages of the disease, because the early stages do not kill and rarely come to autopsy, he rarely, therefore, has the opportunity to see them.

Thus, each of these diagnosticians has his limitations dependent on his opportunity actually to see the disease in its early stages. So far as seeing early cancers is concerned, dermatologists, endoscopists, roentgenologists, surgeons and surgical pathologists are the only physicians who have this opportunity. Perhaps this sounds like professional heresy, but the following fig-

ures substantiate the statement I have recently studied more than 1,200 cancers the size of a quarter (24 mm) or smaller found surgically in the breast, stomach and large intestine. None of these gave positive characteristic signs or symptoms of cancer but all gave signs and symptoms of conditions that are sometimes, but not always, associated with cancer. There are only two reasons why these relatively small cancers were discovered. They were suspected in spite of the absence of textbook signs and symptoms and the patients were explored endoscopically, roentgenologically, surgically and microscopically while they were alive. They therefore received immediate complete and thorough examinations, an attempt being made to rule out cancer before it reached the stages of clinical recognition.

What constitutes a small or early cancer might be a question. I have arbitrarily chosen 2.5 cm in diameter, because this is much smaller than the average size of operable cancers in the organs I have mentioned. In a series of 7,750 surgically removed cancers that I have measured, the average diameters were for the breast 3.2 cm, the stomach 6.1 cm, the rectum, rectosigmoid and sigmoid 5.7 cm, and the rest of the large intestine 6.9 cm. Such averages do not represent the average size of cancers as they are actually being recognized by general physicians, because only 50 per cent of all cancers of the breast, 25 per cent of the stomach, 58 per cent of the large intestine, 65 per cent of the body of the uterus, 85 per cent of the cervix, and 75 per cent of the lip are operable when first seen by the surgeon. These percentages of operability suggest that the disease is not early when discovered by the medical profession as a whole. Of those operable, 62 per cent of the cancers of the breast, 53 per cent of the stomach and 38 per cent of the large intestine have glandular involvement. In general it may be said that cancer is certainly not being diagnosed early despite the repeated pleas of surgeons and the campaigns of the American Medical Association, the American College of Surgeons and the American Society for the Control of Cancer, each of which has thoroughly propagandized the country from end to end, spent thousands of dollars, and has been generously assisted and supported by a very willing press. I have not the slightest doubt, however, that their efforts have rendered a most valuable service so far as popular education is concerned, but the job is far from finished, the problem is not yet solved so far as early diagnosis and early treatment are concerned.

The second part of the problem, namely, the statistical frequency of the disease, has been abundantly studied. The figures, although perhaps not absolutely accurate, are sufficiently correct to awaken interest and suggest serious consideration. Cancer is a very common disease. Whether 100,000 or 150,000 die this year or next is very tragic, but nothing can be done about those who are dead or those who are going to die next year. The latter might be made comfortable but they will not be cured. The important group to consider is the one now unconsciously waiting to die five, ten and fifteen years hence. Cancer does not have a life history of just a few months or one year, it is a disease that usually takes several years to run its full course. Those who have studied the clinical histories of a large series of cancer patients must be aware of the fact that most of them have a longer story than appears on a superficially taken history. Despite the

fact that this disease does occasionally slip up on its possessor unawares, this is far from being the general rule. I myself am not interested in the 100,000 or 150,000 that will die this year, I am certain their cancers are much larger than the average sizes I happen to know are being operated on. It is the patient with a lesion smaller than a quarter that I think the general practitioner must consider seriously if he is to continue his duty in relation to the problem.

The third part—the application of empirical methods of treatment—has a history that is a medical epic equal in greatness to any social epic in any land. Time forbids its complete review, one must be satisfied with a mere suggestion. By way of illustration, the history of surgery may be considered in its relation to the treatment of gastric cancer, which happens to be the most frequent form. In view of the fact that pure medical treatment of cancer has always had a 100 per cent mortality preceded by suffering and slow death, it was the object of early surgeons to relieve the suffering first by some sort of gastro-enterostomy or pyloroplasty operation and later, when their technic became perfected, attempt the removal of the disease itself. Wolfner in 1881 reported his technic for gastro-enterostomy and during the same year Billroth did his first successful gastric resection for cancer. It must be remembered that little was then known of the cause of infection and how to prevent it. Pasteur had just isolated the streptococcus and staphylococcus, and although empirical antisepsis had been practiced by Lister, Kirchenmeister, Lemaire, de Morgan and others, abdominal surgical exploration was not possible until the development of asepsis, which awaited the further work of Pasteur, Koch and others. It may be said that the developmental technical period was from 1880 to about 1910, a period of thirty years. Operative mortality for removal of gastric cancer dropped from 100 per cent in 1880 to 9.5 per cent and less in 1906, at which time gastric operations became much more frequent and time was sufficiently long for a study of results. W. J. Mayo, as far back as 1910, reported 20 per cent of his eighty-five patients who had had gastric resections for cancer alive and well after four years, two alive over eight years, two over six years, and two over five years. This was certainly better than letting them die of slow starvation, anemia and metastasis.

From 1910 both the immediate risk of operation and the postoperative results have continued to improve with resultant greater frequency of diagnostic exploration and therapeutic resection, both of which have provided abundant opportunity for the surgeon, endoscopist, roentgenologist and surgical pathologist to see cancers long before they have had a chance to make themselves apparent by textbook signs and symptoms of cancer.

To this review of the surgeons' efforts must be added the more recent and shorter history of the application of x-rays, which have a very definite place in successful diagnosis, therapy and alleviation. While no one would be bold enough to suggest that the empirical methods are perfect or 100 per cent efficient, fairness demands must admit their excellent results despite the fact that they have not been given half the chance by the profession that their merits deserve. It is quite obvious to those who follow results that the chances of effecting good results are indirectly proportional to the size of the cancers when treated. In spite of all scientific research there has been no method of treatment that

has given anything that even approaches the results of surgeons and radiologists, each in his proper place. Blame cannot be placed on surgeons, roentgenologists, radiologists, popular cancer propagandists, general physicians, laymen or pure scientists for the slowness of progress, the fault does not lie in their direction but rather in the inherent sluggishness of educational methods, which reminds me of one of my favorite quotations: "The longer I teach the more I am impressed with the infinite capacity of the human mind to resist the introduction of knowledge" (Lounsbury).

This leads me to the fourth and last part which I shall consider—that one which has to do with the education of the medical profession itself and future members of the profession. The layman may be dismissed at once. I believe there are probably very few individuals in the United States over 21 years of age who have not heard about cancer, thanks to the campaigns that have been conducted by the profession and the lay press. On the other hand, I am not so certain that the organized medical educational system has done all it can do. Having been for years intimately associated with medical students, recent medical graduates and practicing physicians from schools from all parts of this country and abroad, I must confess that I am chagrined at the lack of practical knowledge of the early stages of cancer and their relation to other diseases. Only cancer in its late stages is being taught. May I bring my opinion to a point abruptly by saying that no teacher of medicine and no teacher of pathology can teach the early stages of cancer by selecting for teaching purposes clinically recognizable cases of cancer and the dead. This can be done no more than the circumstances that lead to war can be taught on the battle field.

Cancer is a biologic disease and its living phases including its initial phase, must be brought to medical students and practicing physicians. What modern ornithologist would be satisfied to teach the life history of birds and their habits from stuffed dry skins, valuable as they may be as records? So far as cancer is concerned, why should it be taught only in the clinical wards and at autopsy tables when the surgeons are offering opportunities to see cancer long before it gives recognizable and characteristic signs and symptoms? Bronchitis is taught as something to be immediately differentiated from early tuberculosis, physicians do not wait for the signs and symptoms of consumption, a term that has been relegated to the past, just as the term cancer will be in the very near future.

Cancer is, in my opinion, a simple problem, although the various specific causes may never be known and no specific cure ever found. It is a problem of health in general, external and internal cleanliness, and heredity. It is, so far as the profession is concerned, a problem of prevention, which means early recognition and treatment of things which frequently end in cancer. It is a disease that is the result of disease.

Now that philanthropists have endowed medical schools, hospitals and research institutions, it is time for some one to endow a system of teaching for general practitioners. This most important member of the profession is the one who sees but does not recognize small cancers. He must have the knowledge brought to him directly by clinics held in his immediate vicinity. He is too busy to read special journals on cancer, he has no time to attend distant special meetings. If famous surgeons and diagnosticians come to him directly they are—often unjustly—criticised, they are accused of soliciting practice. The medical profession has

always been altruistic, it has always given more than it received, severe and unfair criticism exists nevertheless.

Some well trained individual or some group must be endowed to travel and teach without expectation of financial compensation from practice. The method of education of general practitioners today is similar to the teaching of the proprietary medical schools, which have disappeared through financial endowment. The change can be made at very little cost, by this method the almost complete eradication of this scourge can occur in the next thirty to fifty years.

I have spoken very plainly because I have seen too many tragedies that might have been avoided. At present these tragedies are no one's fault. No one is to blame. The problem today is one of education, rid of the criticism that of necessity occurs in any form of proprietary teaching. I believe very firmly that there must be some form of endowed education carried directly to doctors. This is even more important than the establishment of institutes of research, which have certainly produced tremendous progress and justified their existence. Just as long as medical education of the practicing profession has possible monetary reward, just so long will it be handicapped and just so long will the next generation reach middle life with hopeless cancers.

There are enough known facts if properly and extensively applied to solve the cancer problem. Early cancers can be found, are being found, and are being removed safely. As a certain satirist (Kraus) once said, speaking of the cultures of his particular country, "The level of culture has risen tremendously in the past fifty years, but it is a pity nobody stands on that level." The level of medical progress has risen tremendously, but it is a pity the whole profession has not reached that level for lack of financial resources in a country as rich as the United States.

In conclusion, may I suggest, should such an endowment arise, that it be a memorial to the late Dr. William Henry Welch, who, in my opinion, has done more for human welfare and happiness than any one else in recent civilization. May I suggest further that it be applied in the ethical spirit of the American Medical Association, which represents the whole medical profession in its relation to all the people.

---

**Epidemic Dropsy**—Undoubtedly the most important and the commonest method of depriving the body of protein is through a prolonged or excessive reduction of protein in the diet. Though it has only recently been discovered, as I shall point out, that there is a close connection between protein starvation and the formation of edema, the occurrence of dropsy in states of advanced undernutrition has attracted attention for centuries. It has been described as occurring in epidemics, and for this reason has been called "epidemic dropsy." The descriptive terms used in the literature serve in themselves to indicate the conditions under which it was likely to occur, for we find it referred to as "war edema," "prison dropsy," "hunger swelling" and "deficiency edema." There are interesting accounts of the dropsy which was widespread in the French Army during the Wars of the Sixteenth Century and which was common in the armies of Napoleon. The interesting observation was also made that the swelling was much greater in the soldiers on march or on duty than in those too sick to move about. Many children confined in Paris during the Siege of 1870-71 became edematous, and in the great famines of India and Russia the people have been described as "swollen with hunger"—Longcope, W. T. The Importance of Disturbances in Nutrition in Edematous States, *New England J. Med.* 210:1244 (June 14) 1934.

# THE IMMUNIZATION OF SCHOOL CHILDREN AGAINST WHOOPING COUGH—FRAWLEY

J M FRAWLEY, MD  
FRESNO, CALIF

JOUR. A. M. A.  
SECT. 29 1934

During the past two school years, prophylactic injections of whooping cough vaccine have been given to large groups of primary grade and preschool children in the Fresno public schools.

The vaccine used was the undenatured antigen of *Haemophilus pertussis* described by Krueger, Nichols and Frawley.<sup>1</sup> The method consists essentially of disrupting living bacterial cells by mechanical means and obtaining the endocellular elements by ultrafiltration. Recently isolated smooth strains of *Haemophilus pertussis* are grown on Bordet's medium enriched with human blood. The cells are harvested in buffered isotonic solution, thoroughly washed to remove metabolites, and mechanically disrupted in a ball mill. The resultant suspension is subjected to ultrafiltration through acetic collodion membranes whereby all intact cells and large particles are retained, while material in molecular or colloidal solution passes through. The Kjeldahl filtrate contains the antigen. Micro-nitrogen content of this antigen solution.

The advantages that this vaccine possesses are the following:

- 1 It is made from the virulent phase I organisms, which were described by Leshe and Gardner<sup>2</sup> as the strain of high antigenic activity.

*Controls and Children Vaccinated Against Whooping Cough*

50 children received 8 cc of pertussis vaccine during November 1933	16
Since then 50 children have been exposed to whooping cough	33
49 children developed no symptoms	
1 home exposure	
81 children developed symptoms	
Controls 174 nonvaccinated children who had whooping cough during same period	
Duration of paroxysmal stage	
less than 1 week	9
1 to 2 weeks	49
2 weeks or more	116
	174

terial cells, as human blood is used in place of animal blood to enrich the medium.

In January 1933, injections of this antigen for immunization purposes were given to the first group<sup>3</sup> of school children. Only a small amount was given at this time, the total for each child being 2.5 cc. Many of this group, which consisted of 345 children, were subsequently exposed to whooping cough. The results were encouraging but not entirely satisfactory. During the following school year, in November 1933, larger injections were given to 505 children. Each child received 8 cc in four weekly injections of 2 cc each. Follow up studies in this group have given evidence of much better protection. Since vaccination, eighty children in this group have been intimately exposed to whooping cough. In forty-nine children whooping cough did develop. In thirty-one children whooping cough did not develop. The attack in these cases was particularly mild, twenty-five had a paroxysmal stage of less than one week's duration, five, of from one to two weeks' duration and one of two weeks or more.

The extent of the protection given by prophylactic vaccination can be visualized when these cases are compared with cases that occurred in nonvaccinated children from the same homes and classrooms. One hundred and seventy-four unselected cases of whooping cough study were taken as controls. In this control group the paroxysmal stage lasted less than one week in nine cases, from one to two weeks in forty-nine cases and two weeks or more in 116 cases.

## COMMENT

A study of the results obtained in this group of kindergarten and preschool children indicates that definite protection against whooping cough was given by prophylactic vaccination with pertussis antigen. There was no reaction following injections in nonimmune children.

Considerable local reaction does occur in the case of children who have recently had whooping cough. This is probably an allergic phenomenon<sup>4</sup> and represents a reaction between the specific antibodies in the tissue and serum of the individual and the antigen. This hypersensitivity is gradually lost and after a few years no greater local reaction is produced than in the case of children who have never had whooping cough.

Because of the absence of reactions following injections of antigen solution in nonimmune children, it is possible to carry out a vaccination program on large groups of children entering school life. Such children are particularly in need of prophylactic vaccination, as they are at this time most likely to be thrown into contact with whooping cough. There is not much danger of younger children being exposed unless the infection is carried home from school by the older members of the family. In a recent health survey of preschool children in Fresno County<sup>5</sup> it was found that 70 per cent of the children ready to enter the public school had not yet had whooping cough. Routine vaccination of kindergarten children would remove the danger of

2 The antigenic activity of the vaccine is preserved by this method. It is now generally conceded that bacterial antigens are altered by physical agents such as heat or chemicals and lose their relationship in whole or in part to the organism from which they originated. This conception is founded on the work of Anson and Mirsky on the denaturation of proteins and forms the basis of this method wherein no heat or chemicals are used for devitalization.

3 There is no reaction following its use because the bulk of the bacteria<sup>1</sup> protein has been removed with the killed bodies of the bacteria. Also the toxic filtrate has been eliminated by the thorough washing.

4 There is no danger of sensitization of the patient by foreign serum adsorbed on the surface of the bac-

epidemics which are likely to occur under the present regulations, children being frequently allowed to attend school during the catarrhal stage of whooping cough when the diagnosis is most uncertain but the danger of contagion is greatest

#### SUMMARY

1 Prophylactic injections of 8 cc of active undenatured *Hæmophilus pertussis* antigen were given to a group of 505 nonimmune school children. Injections were followed by practically no local or systemic reaction.

2 Since vaccination these children have been kept under observation. Forty-nine have been exposed to whooping cough without developing symptoms, sixteen were exposed at home and thirty-three at school. In thirty-one children, whooping cough developed. In twenty-five cases the paroxysmal stage was of less than one week's duration, in five cases of from one to two weeks' duration and in one case of two weeks' duration or more.

3 As controls 174 nonvaccinated children from the same homes and classrooms who had whooping cough during this period were classified on the same basis as the vaccinated children. The duration of the paroxysmal stage in these cases was as follows. In nine cases it was less than one week, in forty-nine cases from one to two weeks, and in 116 cases two weeks or more.

#### ABSTRACT OF DISCUSSION

DR LOUIS W SAUER, Evanston, Ill. Dr Frawley's results with a total of 8 cc of Krueger's pertussis endo antigen compare favorably with Madsen's recent report in which a total of 22 cc of potent vaccine was injected sometime before exposure occurred. Both found the disease more severe and more prevalent among the uninjected controls. Dr Frawley has pointed out that endo-antigen does not contain anything which is not present in potent vaccine, its distinctive features are that systemic reactions do not occur and that local reactions are rarely visible at the end of twenty-four hours. As it causes no reactions, why is the total dosage divided into four weekly injections? Since the first smallpox and typhoid immunizations clinicians observed that immunization is often associated with local or systemic reactions of varying degree. Reactions are attributed, at least in part, to the immunizing fraction of the antigen. Immunologists, notably Cannon and Kahn, in recent years, have ascribed to certain cells of the skin an important role in antibody formation. Potent vaccine is thought to exert a specific action first on the local tissues, then on the blood serum. The immunity response should be enhanced by the particulate nature of vaccine which delays its absorption. Faroe Island physicians, for example, stressed the importance of local reactions and Madsen says "The effect is greatest in patients showing a strong reaction at the point of injection. There may be some connection between this and the curve showing the formation of antibody." Mishulow, Mowry and Scott found Berkefeld filtrates of *Bacillus pertussis* cultures strongly toxic and antigenic. The toxin could be neutralized by the serum of a previously immunized rabbit. Gross repeated their Schwartzman and neutralization tests. The Berkefeld filtrates of some strains were so toxic that positive reactions occurred with filtrates diluted 1:25. The reactions that follow the subcutaneous injection of immunizing vaccine (three times the Madsen dosage) have not been sufficiently severe to postpone a subsequent injection. At no time have they caused any great concern. The local redness and rise in temperature are transient whenever they occur and usually disappear within a day or two. These reactions are not due to alien protein rarely do they resemble nonspecific reactions due to bacterial protein. Although allergic reactions have not occurred in any of the 800 immunizations during the past six years it is advisable to give the injections not further than seven days apart. If it should be found that prolonged immunity can be conferred by a

more concentrated and larger dosage of endo antigen, it will probably be given also earlier in life, i. e., at a time when the disease is most serious.

DR H F HELMHOLTZ, Rochester, Minn. This subject is one of the most important that have come before the section, because it is preventive pediatrics, in which field results are just beginning to appear. Whooping cough now stands at the top of the deaths from communicable diseases. The work presented by Dr Frawley and discussed by Dr Sauer opens the way for further study of active immunization. The difficulty at present is that the deaths from whooping cough are largely in the first year of life, so that immunization must be carried out during the first six months of life. The disease much less fatal after this period, nevertheless carries with it complications that are crippling, so that, as far as the infant and the older child are concerned, there is every reason for furthering this work to the utmost. I have had but slight experience with Dr Frawley's vaccine. There was an epidemic this winter in which twenty children were immunized. I had observed these children since birth. I knew their family history. Of this group immunized during the epidemic three developed the disease during the process of immunization. The other seventeen were protected, with the exception of one case. There was for a period of two months constant exposure in schools and in two instances, intimate contact in the home. One of these children who had intimate contact in the home with a brother who developed it five months after inoculation was protected. In the other instance, a child in a home exposed to an older brother did not come down with the disease. This series is entirely too small to be of any definite value, but it shows what can be hoped for when work of this kind is definitely standardized.

DR REUBEN L KAHN, Ann Arbor, Mich. I was interested in Dr Frawley's finding that children who have recently recovered from whooping cough show a marked local inflammatory reaction to a skin injection of his specific protein vaccine. Many workers consider this local reaction an allergic or hypersensitive response. I look on this reaction as an immunologic or defensive response. When Dr Frawley injects his specific protein into a nonimmune child, the protein diffuses from the area of injection and practically no local inflammation follows. The tissues of a nonimmune animal do not possess the capability of keeping a protein or vaccine localized in the area of injection. This capability makes its appearance only after immunization. A sequel to this localizing property is the destruction of the injected protein or vaccine. This destruction is brought about by proteolysis as a result of the inflammation. When therefore, Dr Frawley injects his vaccine in the skin of children who have recovered from whooping cough, there follows a local inflammatory response. Having developed immunity to whooping cough, the tissues have acquired the capacity to enter into some combination with and to localize the injected vaccine, presumably to prevent its diffusion through the body. Inflammation is the next step, to aid in the local destruction of the antigen. Of interest in this connection is the recent report by Francis, from the Rockefeller Hospital that patients who are recovering from type I pneumonia show positive skin reactions to injections of the specific soluble substance of type I pneumococcus, while those who are not recovering from this infection do not show positive skin reactions. The explanation in my opinion is the same as in whooping cough. The patient who is recovering from pneumonia possesses the capacity of localizing the specific antigenic substance and to destroy it subsequently by inflammation. The patient who lacks immunity to recover from the pneumonia lacks the capacity to localize and destroy the specific antigen and when injected into the skin, the antigen diffuses from the injected area and no local inflammation follows.

DR JAY I DURAND, Seattle. It seems that for the first time there is a valuable agent for preventing and treating this disease. I have given Dr Sauer's vaccine to about 150 children during the past year. None of them developed whooping cough after a period of four weeks following the last injection. One developed whooping cough four weeks after the last injection. I don't know whether it is going to be 100 per cent successful but I have had two infants live in the house with older brothers and sisters who have had severe whooping

cough during the last winter, without contracting it. I have had a number of other children in kindergartens where the disease was prevalent, who have not contracted the disease. A number of these children, I should say 5 per cent, have had a reasonably severe febrile reaction the night the vaccination was given. One of the patients had a convulsion. However, none of these children have been ill enough to worry me. All have been well within twenty-four hours after the symptoms of the fever began. The reactions have not been any more severe than those following the ordinary mixed respiratory vaccines. The reaction is not to be considered if there exists, as I believe there does, an agent for preventing this distressing disease. Physicians are immensely indebted to Dr. Sauer for first making available a real method of immunization. I hope physicians are going to feel equally indebted to Dr. Frawley for supplying something that may help in the treatment.

DR. J. VICTOR GREENEBAUM, Cincinnati: I should like to ask a question. Dr. Schwartzman's exhibit downstairs beautifully demonstrates the Schwartzman reaction, which occurs after giving a second dose of filtrate intravenously. I should like to ask Dr. Frawley whether one of these severe Schwartzman reactions could occur if he happened to hit a vein at the time of the second or third inoculation with his vaccine.

DR. J. M. FRAWLEY, Fresno, Calif.: With regard to Dr. Sauer's question as to why the total dosage is divided since there is no reaction, I have felt my way along with this antigen and began, as a matter of fact, with very small doses and am now realizing that much larger doses can be given. I feel sure that as the strength of the antigen is increased so that the dosage will be cut down as much will soon be given in one dose as is now being given in three or four doses. With regard to Dr. Greenebaum's question, there is no danger of the Schwartzman reaction following an intravenous injection of the second or third dose. I tried to elicit the Schwartzman phenomenon in animals and found it was impossible, because the toxic filtrate which is responsible for that phenomenon has been removed by the thorough washing to which the bacteria have been submitted before they have been ground down.

## CARBON TETRACHLORIDE AS AN INDUSTRIAL HAZARD

PAUL A. DAVIS, M.D.  
AKRON, OHIO

Carbon tetrachloride has many uses at the present time. Many years ago it was tried as an anesthetic in place of chloroform but it was too toxic because of the high chlorine content. More recently it has been given as a remedy in hookworm and other intestinal parasitic diseases. It is at the present day used by the veterinary profession in treatment of canines. Perhaps the most frequent commercial uses of carbon tetrachloride today are the following:

- 1 As a solvent in the rubber industry
- 2 As a cleansing agent in the dry cleaning industry
- 3 As a solvent in the chemical and drug industry
- 4 As an occluding and nonoxidizing agent in fire extinguishers
- 5 As a solvent in the paint industry
- 6 As an anthelmintic for parasites in the practice of medicine
- 7 In machine shops for the removal of grease in combination with benzene in order to keep the fire hazard at a minimum
- 8 As a dry shampoo in the hair dressing industry, especially in foreign countries

The chief use of carbon tetrachloride in all of these processes is as a solvent and a diluting agent to reduce the flash point in certain other solvents. Mixtures of carbon tetrachloride and benzene and of carbon tetra-

chloride and benzene in ratios of 60 to 40 and 50 to 50 are unflammable. Carbon tetrachloride is a saturated chlorine derivative of methane,  $\text{CH}_4$ , or marsh gas. Starting with the formula of methane and making substitutions with chlorine one gets, when the saturation point is reached, the extremely volatile substance carbon tetrachloride, which is a clear liquid of high specific gravity. It has a specific gravity of 1.599, a boiling point of 170.6°F and a vapor density of 5.33.

The commercial preparation of carbon tetrachloride is as follows: (1) Chlorination of carbon bisulphide. This method produces many impurities in the finished product, especially some sulphur compounds which are toxic. (2) Chlorination of ethylene. (3) Catalytic action of the electric arc on carbon and calcium chloride.

The most toxic impurities that may be present in commercial carbon tetrachloride are phosgene, hydrogen sulphide, free hydrochloric acid, organic sulphides and carbon bisulphide. Most of these can be removed by distillation and further absorptive treatment. The increasing use of carbon tetrachloride both as a solvent and as a cleaning agent prompted me to investigate the toxicity of this substance. The following experiments were made and the reactions noted:

### EXPERIMENTS WITH CARBON TETRACHLORIDE

A space was used measuring 20 by 20 by 10 feet, equaling 4,000 cubic feet, or 6,912,000 cubic inches, and containing 113,347.5 liters of air.

EXPERIMENT 1—One milligram per liter, or 0.0158 volume per cent, or 126 Gm to 4,000 cubic feet, or 158 parts per million. Exposure, thirty minutes.

1 Age 28 Nervous, slight nausea, pulse 120, respiration 28, blood pressure 145. Blood count normal. Hemoglobin 90 per cent.

2 Age 30 Very little effect. Pulse 85, respiration 18, blood pressure 115. Blood count normal. Hemoglobin 95 per cent.

3 Age 20 No effect. Pulse 76, blood pressure 120, respiration 17. Blood count normal. Hemoglobin 90 per cent.

4 Age 28 No effect. Pulse 70, respiration 18, blood pressure 118. Blood count normal. Hemoglobin normal.

Urinalysis in twenty-four hours gave negative results in all cases.

EXPERIMENT 2—Five-tenths milligram per liter, or 0.0076 volume per cent, or 63 Gm to 4,000 cubic feet, or 76 parts per million. Exposure, two and one-half hours.

1 Age 35 No symptoms. Blood pressure 118, respiration 17, pulse 75. Blood count and hemoglobin normal.

2 Age 48 No symptoms. Blood pressure 130, respiration 20, pulse 78. Blood count and hemoglobin normal.

3 Age 22 No symptoms. Blood pressure 115, respiration 16, pulse 72. Blood count and hemoglobin normal.

4 Age 30 No symptoms. Blood pressure 126, respiration 19, pulse 76. Blood count and hemoglobin normal.

EXPERIMENT 3—Next day the same subjects were exposed for four hours and no symptoms developed from carbon tetrachloride. There was a slight tired feeling but this was due to insufficient oxidation and not to carbon tetrachloride. Urinalyses after seventy-two hours were all negative.

EXPERIMENT 4—Two milligrams per liter, or 0.0317 volume per cent, or 252 Gm to 4,000 cubic feet, or 317 parts per million. Exposure, thirty minutes.

1 Age 20 Slight nausea. Blood pressure 120, pulse 80, respiration 20. Blood count and hemoglobin normal.

2 Age 45 Nausea and vomiting. Blood pressure 150, pulse 88, respiration 25. Blood count and hemoglobin normal.

3 Age 36 Headache. Blood pressure 132, pulse 90, respiration 27. Blood count and hemoglobin normal. Urinalysis after forty-eight hours gave normal results.

EXPERIMENT 5—Eight milligrams per liter, or 0.1191 volume per cent, or 1,008 Gm to 4,000 cubic feet, or 1,191 parts per million. Exposure fifteen minutes.

1 Age 19 Headache, nausea and vomiting Blood pressure 130, pulse 130, respiration 22 Subject could not stay out in nine minutes

2 Age 21 Nausea, vomiting Blood pressure 125, pulse 100, respiration 20 Subject stayed in twelve minutes

3 Age 28 Nausea, headache Blood pressure 122, pulse 110, respiration 20 Subject stayed in fifteen minutes

4 Age 40 Nausea headache, vomiting Blood pressure 142, pulse 128, respiration 20 Subject stayed in ten minutes Urine examination in forty-eight hours revealed no albumin, no sugar, increased acidity, increased phosphates, otherwise negative

EXPERIMENT 6—Twenty-five one hundredths gram per liter, or 0.2382 volume per cent or 1,890 Gm to 4,000 cubic feet, or volume 2,382 parts per million, weight 12,800 parts per million

1 Age 40 Exposure five minutes Dizziness nausea throbbing in head, sleepy Blood pressure 150, pulse 130, respiration 28

2 Age 26 Exposure three minutes Nausea and nervousness, not sleepy but listless Blood pressure 150 pulse 110, respiration 22

3 Age 19 Exposure seven minutes Nausea and vomiting, dizziness, sleepy Blood pressure 129 pulse 115, respiration 23 Urinalysis in forty-eight hours disclosed no albumin no sugar, no casts, no sediment, increased phosphates and acidity, no definite change except temporary Examination in two weeks showed that no ill effects were caused

EXPERIMENT 7—Three men were asked to work with pure carbon tetrachloride by painting it on a fabric in a room that was closed but had exhaust ventilation about 6 feet away from the table over which they worked A sample of the air

in the immediate vicinity of their faces was collected and analyzed by the alcohol potassium hydroxide and combustion method and found to be 0.23 per cent carbon tetrachloride. None of the men could work over ten minutes without becoming nauseated and sleepy one vomited and developed dizziness with a throbbing feeling in his head

EXPERIMENT 8—Since the average man during an eight hour work period inhales 11¾ pounds of air it was thought advisable to see how much carbon tetrachloride he would get in an eight hour period. The air within the working area was examined and found to contain 0.02 per cent of carbon tetrachloride. Several had complained of nausea and had vomited. Several had said they felt tired and sleepy when the day's work was done. Now 0.02 per cent of 11¾ is approximately 0.234 pound in eight hours. It would be 0.37 pound if the weight of carbon tetrachloride was calculated. This is sufficient for our purposes. The odor of carbon tetrachloride can be detected with as little as 0.5 mg to a liter, and at 3 or 5 mg to a liter it is very strong. One man who had been working in the cement house was found to have albumin in the urine. He was removed and placed on other work and the urine was examined weekly. At the end of two months the albumin had disappeared. The phenolsulphonphthalein function test showed him to have 90 per cent function. He was not placed in carbon tetrachloride after that. He was continued on his work without after-effects becoming noticeable. The albumin cleared up and there was no microscopic evidence of any pathologic condition in his urine. There probably will never be any trouble, as the rest of the kidney tissue has taken up the work.

A rabbit was exposed to carbon tetrachloride 20 mg per liter for three hours daily for three days. It died on the fifth day. Autopsy showed the lungs to be full of mucopurulent material. The kidneys were injected and had hemorrhagic spots. The intestinal mucosa was injected and red. The stomach was injected and showed some edema. The eyes were reddened and showed evidence of conjunctivitis. There was a beginning central necrosis of the liver.

Eight men were engaged in spraying cellulose cement on the end of liner rolls to be sent to Australia. These men constantly complained of nausea, headache and fatigue at the end of the day. The air was examined and found to contain 0.037 per cent of carbon tetrachloride. This condition was corrected and the spraying was done under a suction hood with a suction floor grating. Later inspection did not reveal any odor of carbon tetrachloride and the men said that conditions were satisfactory and they did not have any further trouble. The men in the cement house experienced the same condition and after correct ventilation was installed, no symptoms were complained of.

One milligram in a liter, 24,450 divided by the molecular weight of carbon tetrachloride, is 153.85, 24,450 divided by 154 is 158.8 the number of parts in a million from 1 mg of carbon tetrachloride.

A guinea-pig was exposed to carbon tetrachloride, 15 mg per liter daily for three days, then 10 mg for four days and finally 300 mg. The guinea-pig died in two and one-half hours. The autopsy showed congestion of the lungs and bronchial tubes, with a serous exudate. The stomach was congested and inflamed. The liver showed mottled areas representing a central necrosis. The kidneys showed a congestion with what appeared to be a cloudy swelling.

From these experiments and examinations of many persons exposed to carbon tetrachloride fumes, it appears that the following symptoms may be caused:

- Slight headache
- Nausea. In many cases this becomes severe and lasts for several days
- Nervousness
- Mental confusion
- Loss of weight
- Dry dermatitis
- Secondary anemia
- Slight jaundice
- Chronic spasms of muscles
- Necrosis of the liver
- Acidosis
- Phosphaturia and irritative nephritis
- Loss of consciousness
- Coma and death
- Visual disturbances, such as blurred vision, color confusion and disturbance of near vision

Dr L. T. Wirtschaffer of Cleveland has recently reported a number of cases in which a toxic amblyopia was present and states that the examination of the visual fields may be a valuable procedure for the early detection of carbon tetrachloride intoxications. There have been several cases reported in which carbon tetrachloride produced fatty degeneration of the liver, kidneys and heart with a subsequent necrosis. The action of carbon tetrachloride is very similar to that of chloroform except that it is more intense. This is due to the larger amount of hydrochloric acid liberated as it is broken down in the body.

Carbon tetrachloride plus hydrogen plus oxygen plus the influences of the body produce four molecules of hydrochloric acid, plus the oxidation products of carbon, carbon monoxide, and intermediate oxidation products, the most poisonous of which is carbonyl chloride (COCl<sub>2</sub>) or phosgene.

Alcohol seems to act as a catalytic agent for carbon tetrachloride and intensifies its action. A person who is under the influence of alcohol when exposed to carbon tetrachloride becomes disoriented and often becomes maniacal.

#### MODES OF ABSORPTION

The modes of absorption of carbon tetrachloride are

- 1 Inhalation of the fumes of carbon tetrachloride
- 2 Alimentary system absorption. Carbon tetrachloride is sometimes given in small doses as a medi-

cament for hookworms and in a short time it is followed by a purge, which prevents much absorption

3 Absorption by the skin and its appendages Dr Alice Hamilton reports a case in which a woman collapsed and died while having her hair shampooed with carbon tetrachloride How much absorption takes place by the hair is not determined, but I believe that the greatest absorption in this case was due to inhalation, as the heavy fumes gravitated about her nose and mouth Dr K O Möller has recently presented several cases of poisoning as a result of the use of carbon tetrachloride in the hair dressing profession and to any one who is interested in this type of exposure there is much valuable information available

Carbon tetrachloride extracts the fats from the skin and produces a dry condition, which favors absorption and also initiates a dry dermatitis, causing the skin of the hands to crack Often this produces avenues for secondary pyogenic infections This condition can be corrected if the workmen will use oil of theobroma, petrolatum or a good grade of ointment of rose water (nonvanishing cream) on the skin after having used carbon tetrachloride

As with most volatile substances, the principal avenue of absorption is the respiratory system The occasional inhalation of small amounts of carbon tetrachloride produces very little effect unless the concentration is very high, and the lower the concentration the less the immediate effects produced Dilutions of 0.01 per cent show very little effect over a period of six to eight hours, but if this continues daily without intermediate aeration, accumulative effects are shown and chronic carbon tetrachloride poisoning occurs Concentrations of from 0.1 to 0.5 per cent produce very little effect if only a short exposure is made and not repeated until the next day

The nausea and vomiting produced by exposure to carbon tetrachloride is due to a central nervous system reaction and not a local gastric one I recall one case that was very amusing A man was working on a traveling crane in a low ceiling building in which a mixture of carbon tetrachloride and benzene was being used over heated mandrils There was enough heat generated to make the carbon tetrachloride very volatile and he was getting the effect of it, with the production of nausea and vomiting He did not realize that the gastric disturbance was due to the fumes of carbon tetrachloride When he went on his crane each morning he took a bucket to be used as a receptacle for his vomiting He later reported to me and his condition was found to be due to the carbon tetrachloride and not to indigestion, as he thought The condition was remedied at once by proper ventilation and reduction of the amount of carbon tetrachloride used

If the concentration of the carbon tetrachloride is kept at a minimum and the circulation of air at a maximum, very few symptoms are noticed A concentration of 0.01 per cent and lower can be tolerated for long periods of time However, I do not advocate a continued exposure to carbon tetrachloride of low concentrations, for slow absorption produces the chronic stage of the poisoning and the retrograde changes in the liver, kidneys and the hematogenic organs

#### PREVENTIVE MEASURES

I have always maintained that most volatile and toxic substances can be used if it is necessary, but the method of using the substance must be in perfect accord with the nature of the substance

Ventilation is one of the most important items This may be in the form of suction or forced ventilation The properties of the substance must be known For example, carbon tetrachloride is heavier than air and seeks the lowest level, therefore the chief part of the ventilation should be suction at the lowest level If carbon tetrachloride is used in vats, tubs or containers, necessitating removal of the covers, there should be hood ventilation with a baffle plate tube surrounding the top of the container, with sufficient suction to remove the fumes as they arise when the lid is removed When carbon tetrachloride is used in paints as a solvent, these painting operations should be carried out under a hood with both overhead and floor ventilation Carbon tetrachloride should not be used to shampoo hair

The type of personnel employed to work around carbon tetrachloride should be selected The following types should not work where there is a concentration above 0.01 per cent

- Very obese persons
- Undernourished persons
- Any one with pulmonary diseases
- Those with gastric ulcers or with a tendency to vomiting
- Persons with hypertrophic or atrophic liver condition
- Those with nephritis or diabetes
- Persons with glandular disturbances especially enlargements of the thymus and the thyroid
- Persons with blood disturbances or myocardial degeneration

Substitution products should be used in place of carbon tetrachloride in all processes in which the change is possible The workers should be rotated so that one individual has a chance to aerate completely and eliminate the products of carbon tetrachloride decomposition while the other is working

Frequent examinations should be made with periodic inspection of the processes and determination of the carbon tetrachloride concentrations used Frequent physical examinations are very valuable as an indication for the removal of a worker from the vapor of carbon tetrachloride The use of carbon tetrachloride should be confined to closed systems and, if this cannot be done, some other substance should be substituted Persons who are working with or around carbon tetrachloride should be examined frequently If after examination any of the following symptoms are elicited, the worker should be removed and placed on a job in which there is plenty of ventilation and fresh air

- Persistent nausea after having worked in very low concentrations for several eight hour shifts
- Loss of appetite and loss of weight
- A 15 per cent reduction of hemoglobin
- Hyperacidity of the gastric contents
- Hyperacid urine
- Persistent headache after eight hours of rest and aeration
- Decreased blood pressure
- A marked poikilocytosis and anisocytosis

The condition that usually follows nausea and loss of appetite is acidosis, and this is manifested very readily in those who perspire freely An irritative dermatitis which becomes very annoying develops in the body folds

While carbon tetrachloride is a very desirable solvent and a diluent for benzene to prevent fire, it is at the same time a very toxic substance even in its purest state The redeeming feature of the toxicity is the fact that it produces symptoms by very slight absorption, and removal can be made before any serious conditions develop

# TREATMENT

The treatment of toxicity due to carbon tetrachloride is as follows

- Removal from contact with the substance
- Aeration—fresh air, oxygenated if necessary
- Alkalinization with sodium carbonate, calcium carbonate or intravenous calcium gluconate
- Ingestion of levulose, dextrose and animal fats
- Tincture of digitalis to protect the heart
- Hexylresorcinol for kidney irritation
- Intravenous administration of physiologic solution of sodium chloride and dextrose or Fischer's solution
- Transfusion if necessary, followed by the administration of iron compounds

If any bronchial conditions develop, which is common after the use of certain impure grades of carbon tetrachloride, owing to the free chlorine and carbonyl chloride, inhalations of compound tincture of benzoin and pine needle oil, followed by some soothing syrup containing codine unless the condition of the kidneys and liver contraindicate it

- Free catharsis
- Forced liquids and starchy foods

Epinephrine should not be used in cases of carbon tetrachloride poisoning if there is a possibility of any myocardial involvement

Carbon tetrachloride is an industrial hazard when the vapor is permitted to escape into the open room and its concentration is constantly above 0.01 per cent. The hazard can be removed by proper ventilation and using the substance in closed systems. Frequent examination of the workers will enable one to rotate them or remove them from contact with the fumes and will prevent the development of any serious condition. Research workers will no doubt provide a nontoxic substitute for carbon tetrachloride or will produce a diluent for benzene or gasoline that will eliminate the hazard.

Supervised selection of individuals to work with this substance will greatly eliminate the hazard. I am of the opinion that a single exposure to carbon tetrachloride in small concentrations does not produce any serious lasting changes, but the daily exposure with the cumulative effect produces very definite pathologic changes which deserve attention. The use of proper ventilation and safety appliances should prevent practically all cases of poisoning except those emergency ones over which there is no control.

985 East Market Street

## ABSTRACT OF DISCUSSION

DR C P McCORD, Cincinnati. In my experience about one industrial plant in two will make use of carbon tetrachloride, although in the greater number its use is limited to fire extinguishers. Dr Davis spoke of skin absorption and recognized it as a practical hazard—a practical source of entry. In our animal work we found that carbon tetrachloride readily enters the intact skin. The unshaven skin, to which carbon tetrachloride was applied under conditions that prevented entry by inhalation, promptly led to the characteristic manifestations of carbon tetrachloride poisoning. This means that if animal work may be carried over to human beings, protection against inhalation of carbon tetrachloride may not always be sufficient. Some consideration perhaps should be given to the possibility of entry through the skin. Dr Davis mentioned the respiratory disease involvement in carbon tetrachloride poisoning. In practical work and in experimental work I have often observed a bronchitis and other forms of irritation of the respiratory tract directly resulting from carbon tetrachloride. Carbon tetrachloride may be a contributing factor in pneumonia. The methods for testing carbon tetrachloride in the atmosphere are

difficult. As a rough method of appraising the situation, if carbon tetrachloride odor may be readily detected in any work room it is nearly always true that enough is there to be harmful, particularly if the exposure is long continued. I do not offer that as a precise test but merely as a suggestive one. No discussion of carbon tetrachloride poisoning should fail to mention the work of Lamson and his associates. Although it primarily has to do with the use of carbon tetrachloride in the treatment of hookworm and similar diseases, it furnishes a great deal of information of value to industry.

DR Z T WIRTSCHAFTER, Cleveland. Dr Davis said that the carbon tetrachloride mixtures were nonflammable. It would be well to remember that the evaporation rate of carbon tetrachloride is much greater than that of gasoline. When the mixture evaporates the halogen compound is the first one to escape, with the result that the originally nonflammable substance may now be inflammable. Lamson found that carbon tetrachloride produced a liver necrosis with an increase of guanidine in the blood and a subsequent fall in blood sugar. A lipemia and a cholesterolemia have been shown to be present in carbon tetrachloride poisoning as a result of central necrosis and fatty degeneration of the liver. I too found that men exposed to carbon tetrachloride had blood dextrose concentrations that were at the lower border of the normal and in some cases even below. I also found a toxic amblyopia in all my cases. This bilateral constriction of the peripheral visual fields returned to normal after the men left their work and were put on a high calcium and dextrose diet. The constriction of the color fields is marked even in the mildest case. It is of significance that carbon tetrachloride intoxication can be detected at an early stage by routine perimetric examination of exposed workers.

DR E R HAINHURST, Columbus, Ohio. Few cases of intoxication are reported annually to the Ohio State Health Department. I think there is a reason other than the heavy specific gravity of its vapors, which causes them to fall to the floor. The chief feature of the three cases in our last year's reports was the association with heating the substance, by which its volatility was increased. Several cases occurred recently in one manufacturing company. None lasted over forty-eight hours and the symptoms were those of the digestive tract only and did not amount to much. Three or four years ago however, a school janitor died of liver symptoms four days after he had applied twelve 1-pound cans of wax to a basement gymnasium floor. The wax was dissolved in a mixture of 48 per cent carbon tetrachloride and "turpentine and a light petroleum distillate 52 per cent." This was, of course, a mixed poisoning, a point I wish to make. I think that the admixture of other solvents, particularly of petroleum compounds, increases the danger (similar to alcohol). I don't believe that carbon tetrachloride is used any more as a hair cleanser, although it formerly was. Here it was mixed with other solvents in at least some of the reported cases. But whether pure or not, it should never be used as a shampoo. A recent extensive summary of the hazards of carbon tetrachloride is that by K. B. Lehmann of the Institute of Hygiene, Wurzburg in the *Zentralblatt für Gewerbehygiene* 7 123 (May) 1930.

DR WILLIAM D McNALLY, Chicago. I should like to ask Dr Davis whether he determined the blood calcium in any of these patients. A calcium deficiency is claimed by the plaintiff in these cases. One law firm in Chicago had nineteen such cases. They occurred in a refrigerating organization in which the men were removing grease from a part of the electric refrigerator unit. Probably others in the country have the same problem. We have many cases, because when the heat is generated by electric soldering it evaporates the carbon tetrachloride, and the workers inhale it. An interesting fact about the workers in that particular industry is that if they feel sick they go out and get a sandwich, and it stops all nausea.

DR WILSON G SMILLIE, Boston. Samuel B. Pessoa and I had the first case of carbon tetrachloride poisoning reported in the treatment of hookworm disease. We gave the tetra-

chloride on a plantation in the interior of Brazil and had a very serious time with an alcoholic addict

DR P. A. DAVIS, Akron, Ohio Dr Hayhurst says that the reason he hasn't got so many reports is that there aren't so many cases and that the small amount of tetrachloride required to produce nausea brings the individual to the hospital to find out the cause. If a man employed in a department using carbon tetrachloride states that he cannot keep his breakfast down, an alert physician immediately knows that the man is absorbing too much carbon tetrachloride. If he is removed from the job he will be all right in twenty-four hours. On determining the blood calcium I have found that it has decreased in every case. In cases of headache, nausea or vomiting, complete aeration for from twenty minutes to two or three hours will bring about improvement, and a disappearance of symptoms in four or five hours. My plea is: Don't expose workers day in and day out until an accumulation is built up, leading to an acidosis, a central necrosis or beginning necrosis of the liver. It is too late then, and the men must be given compensation, and the more men you put on compensation, the less valuable one is to one's company.

## SONNE DYSENTERY

JOSEPH FELSEN, M.D.

AND

A. G. OSOFSKY, M.A.

NEW YORK

Sonne dysentery is an inflammatory condition of the small and large intestine characterized by a bloody and mucoid diarrhea accompanied by colic, having a short incubation period and being of a relatively nontoxic type. The disease is caused by the *Bacillus dysenteriae* of Sonne, which has many points of clinical, cultural and agglutination similarity to the organism causing the Flexner type of dysentery, for which it is often mistaken.

Our purpose in this communication is to present the general subject of Sonne dysentery and the detailed clinical, bacteriologic and experimental studies of a recent outbreak. The disease has been practically unknown in the United States. There is reason for believing, however, that this distinctive type of dysentery has been overlooked, that it is endemic in many parts of this country, that it can assume epidemic proportions and that there is a possible connection with certain intestinal and arthritic diseases of obscure origin.

Although other investigators, notably Duval and Shorrer,<sup>1</sup> described an organism similar to the bacillus of Sonne in diarrheal disease, the latter investigator<sup>2</sup> in 1915 was the first to establish a definite etiologic relationship to dysentery. Since then reports have appeared from various parts of the world (France, Denmark, Norway, Sweden, Japan, Scotland, England, Australia, South Africa, Canada and the United States). Bamforth<sup>3</sup> and Smith<sup>4</sup> in 1924 described the organism as a cause of enterocolitis in England, and Channon<sup>5</sup> in 1925 recovered the bacillus from a patient who had previously had dysentery in Egypt. The first report of

the disease in South Africa appeared in 1930, when Buchanan and Rau<sup>6</sup> described five cases. In Canada, Johnston and Brown<sup>7</sup> in 1931 described twenty cases of Sonne infection in a series of 175 children suffering from intestinal intoxication or infectious diarrhea. Since 1929 several reports have appeared in the United States, notably the outbreaks described by Gilbert and Coleman<sup>8</sup> in 1929, Nelson<sup>9</sup> in 1931, Silverman<sup>10</sup> in 1932, Welch and Mickle in 1932<sup>11</sup> and Soule and Heyman<sup>12</sup> in 1933.

### GENERAL CLINICAL FEATURES

**Age Incidence**—In the majority of cases, those affected have been children under 10 years of age. It is surprising, however, with the limited literature at our disposal to note the number of adults affected.<sup>13</sup> It appears quite probable that under proper conditions of medical and laboratory control an increase in the frequency of the disease in adults will be noted, for with few exceptions, adult cases have been detected only during the course of an epidemiologic survey. The mildness of the symptoms in older people, as thus far encountered, probably accounts for the infrequency of diagnosis. This point will again be stressed in discussing the carrier problem, in explaining the endemic nature of the disease and in noting the severity of the disease in outbreaks of epidemic nature.

**Seasonal Incidence**—There is no definite seasonal incidence. The disease may occur in endemic or epidemic form at any time, though most of the large outbreaks have been in winter.

**Social Aspects**—Except when the disease has started in hospital wards, it appears to be most prevalent among the poorer classes. Being essentially a contact infection, it frequently affects many members of the same family. In our studies positive cultures were obtained in all three children of one family, including the patient to whom the outbreak was finally traced. The importance of general good hygiene and sanitation is stressed by the observations of Fyfe, who reported an epidemic affecting 150 persons. This was a milk-borne outbreak started by a dairyman's wife. The cases reported by Gilbert and Coleman in New York State included five occurring in a city during an out-

break of intestinal disorders associated with a polluted water supply

**Symptomatology**—From the standpoint of symptomatology, Sonne dysentery may be divided into three main types

**1 Symptomless Type** In this group the diagnosis is made incidental to an epidemiologic survey and no history of indisposition, fever or diarrhea can be obtained. The fecal cultures or agglutination tests are positive and the individual concerned can definitely be ruled out as a carrier. In borderline cases only the most careful questioning will elicit a doubtful history of a few loose bowel movements but no other symptoms. Sometimes a history of a transient attack of "food poisoning" resembling *Salmonella* infection may be obtained. It is quite possible, too, that some of the cases of toxic arthritis of unknown etiology, but known to occur in Flexner and Shiga dysentery, fall in this group. Arthritis occurring in dysentery is of particular interest, too, as bearing a possible relationship to a similar condition quite frequently seen in idiopathic ulcerative colitis, for it is generally admitted that the latter disease, in some cases at least, may be the aftermath of an undiagnosed bacillary dysentery or a recognized type in which the specific organisms and the agglutination titer have disappeared.

At least three of our cases fall in this group

**CASE 1**—B S., aged 7½ years, operated on for mastoiditis and sinus thrombosis, during an uneventful convalescence had a soft bowel movement of which a culture was made and found to be positive. There were no symptoms referable to the intestinal tract no rise in temperature or diarrhea. The duration of the illness was one day.

**CASE 2**—S T., aged 2 years, convalescing from pneumonia, had two loose stools with mucus on the first day and three loose greenish stools on the second day. There were no other signs or symptoms and no change in temperature, which had been ranging between 99 and 100 F. The duration of the illness was two days.

**CASE 3**—I S., aged 10 years, operated on for acute appendicitis with subsequent uneventful recovery, had four loose bowel movements nine days after operation and on the following four days five, one, three and one. There were no constitutional symptoms and no rise in temperature. The duration of the illness was five days.

**2 Mild Type** Most of the reported cases in older children and adults have been mild. This is the characteristic form of the disease as generally encountered up to the present, thus marking it off at once clinically from the Shiga and Flexner types. The distinguishing clinical features are the shorter duration and a lessened tendency to pyrexia, tenesmus and profuse bloody stools than the other forms of dysentery. The onset is generally without noteworthy prodromal symptoms other than slight lassitude or anorexia. The only symptoms may be a mild diarrhea with mucus, soft greenish diarrheal or watery bowel movements and a little abdominal discomfort. There may be little or no rise in temperature. The stools vary from three to eight or more per day and usually contain specks or larger quantities of bright red blood. The surprising fact is the well being of the patient, who complains little or not at all. After a period varying from a few days to perhaps two weeks the bowel movements gradually subside the feces become well formed, and the disease appears to be at an end. There are generally no bad after effects, no noticeable prostration and no pronounced anorexia or loss in weight. Practically all of our cases among children fell in the mild group. The

majority of our patients could be grouped under the mild type of the disease. The following are examples

**CASE 4**—M S., a girl, aged 8 years, admitted with dysentery which was incorrectly diagnosed as acute appendicitis, complained of pain in the right loin radiating to the umbilicus of one day's duration. This was accompanied by anorexia, headache and three attacks of vomiting. There was some tenderness over McBurney's point and in the right loin. The urine contained some albumin. The total leukocyte count was 4,000 per cubic millimeter with a normal differential. The admission temperature was 101.2. At operation there was found a quite normal appendix but an enlarged mesenteric lymph node. Pathologic examination revealed moderate lymphoid hyperplasia of the solitary nodules in the appendix and marked lymphoid hyperplasia in the node, but no necrosis. On the day of admission there were many bowel movements and on subsequent days they varied from three to nine, the average being seven. During the first three days, bright red blood was present. The postoperative temperature varied from 98.6 to 100 F. The patient served as the focus of dissemination in the outbreak and was followed up for four months. The positive fecal cultures and high agglutination titers of the serum continued for approximately four months.

Several points are noteworthy with regard to this case. At least two other instances of Sonne dysentery being mistaken for appendicitis are reported in the literature.<sup>14</sup> The misleading symptoms suggesting appendicitis and the mesenteric adenitis are due to the marked lymphoid hyperplasia seen in Sonne dysentery. This is most evident in the region of the ileocecal valve, where edema and a ring of lymphoid hyperplasia may be noted. This, as well as mesenteric adenitis, have already been described by other investigators.<sup>15</sup> Evans made special note of the enlarged nodes at the ileocecal angle. The other features of case 4 are the low total leukocyte count and the unusual persistence of positive cultures. Those in the other two children of the family did not remain positive quite so long. Fecal cultures in Sonne dysentery usually do not remain positive for more than one to three weeks, which practically excludes the possibility of the carrier problem in this disease. The duration of the illness was approximately two weeks.

**CASE 5**—R W., aged 8 years, developed dysentery after the resolution of a lobar pneumonia. Without any prodromal symptoms there occurred a sudden rise in temperature from 98.2 to 103.6 F. On the same day there were four loose watery, bloody bowel movements containing some mucus. The temperature dropped on the following day to 99 and remained at that level for the next five days, when there were five, five, five, two and one bowel movement. The duration of the illness was six days.

**CASE 6**—G M., aged 10 years, was convalescing from lobar pneumonia. Except for slight abdominal cramps, the onset was sudden with no prodromal symptoms. Six diarrheal movements with blood and mucus occurred on the first day and were accompanied by a rise in temperature from 100 to 104 F. The average on the subsequent four days was three stools. The duration of the illness was five days.

**CASE 7**—P H., aged 14 months, convalescing from bronchopneumonia had a sudden onset with vomiting. Six foul, green, watery bowel movements containing mucus occurred on the first day. There was a slight rise in temperature from 99 to 100 F, with a prompt drop to 99 on the second day, where it remained except for a recrudescence to 101.4 on the fifth day. There were no constitutional symptoms. The bowel movements varied from one to nine a day, the average being five. The duration of the illness was twenty-six days. This case is noteworthy because of the long duration of active symptoms. Sonne dysentery is apt to manifest its gravest form in infants.

**3 Severe Type** The onset is sudden and suggestive of a severe Flexner infection with abdominal pain, and diarrheal stools containing mucus and blood. Vomiting may be severe, accompanied by profound pros-

<sup>14</sup> Clayton & Nelson.

<sup>15</sup> Harvey E. Dysentery as a Cause of Sudden Death. *Lancet* 1: 190 (Jan 28) 1933. Evans W. H. Fulminating Dysentery in Child, *Cau ed by B. Dysenteriae Sonne Brit M J* 2: 96 (July 21) 1928.

tration Some of these cases are mistaken for "food poisoning." Anorexia is marked. Dehydration and acidosis are prominent features, especially in infants. The temperature remains quite high for several days, reaching 104 or 105 F. The drop to normal generally coincides with the cessation of diarrhea and improvement of subjective symptoms. This type is apt to occur in infants during epidemics. Our severest cases were encountered, however, in adults and, though of very short duration, were characterized by sudden onset, profound prostration and severe bloody diarrhea lasting one or two days. This was quite striking, as the cases occurred at the height of the outbreak among the children who appeared to be remarkably well. It points to the strange vagaries of Sonne dysentery. Of course we

were four loose stools containing mucus. The pyrexia gradually reached 104 on the third day and then fell to 99 on the sixth. The maximum daily stools were six. The duration of the illness was six days.

#### EPIDEMIOLOGIC STUDY OF HOSPITAL OUTBREAK

The following data concern an epidemiologic study made of an outbreak of Sonne dysentery which occurred at the Bronx Hospital during the latter part of December 1933 and January 1934.

The existence of an unusual intestinal disturbance among hospital patients first came to the attention of the senior author when a member of the intern staff asked for an opinion on a warm wet smear made from the feces of a patient in the children's ward. He had been endeavoring to find *Endamoeba histolytica*. On questioning, it was ascertained that the child whose specimen he was examining had had several diarrheal stools with blood and mucus. The absence of *Endamoeba*, the search for which the intern had pursued with commendable zeal, and the presence of what appeared to be an acute intestinal condition aroused our interest. It was soon discovered, after careful inquiry, that there had been and still were a number of other cases of unexplained diarrhea in the children's ward. Careful laboratory and clinical studies convinced us that we were dealing with an inflammatory condition of the intestine, characterized by a bloody and mucoid diarrhea accompanied by colic, of the nonamebic type, having a short incubation period, and of a relatively nontoxic type. We ventured the diagnosis of Flexner dysentery and advised that the matter be taken in hand before it spread through the entire hospital. Indeed, within a few days we discovered that approximately twenty men on the engineer's staff had come down with diarrhea, three or four of them bloody, that four or five men on the housekeeper's staff had been similarly affected and, most important of all, a member of the kitchen staff was involved. At first glance, the problem appeared simple and clear cut, i. e., that the outbreak had been started by this member of the kitchen staff, but repeated cultural and agglutination tests were negative for *B. dysenteriae*, all types. While this did not conclusively rule out this individual as being a focus of dissemination, it appeared advisable to seek elsewhere for more positive evidence. It was soon found in the person of a little girl, M. S., who had been admitted to the surgical service for an acute appendicitis. We ascertained, however, that on the day of admission she had had cramps and diarrhea. Her appendix was removed the following day, but the diarrhea persisted (varying from three to nine movements a day), the feces showing bright red blood on two days. On the day of her discharge, eight days after operation, she still was having eight stools a day. At the time of the inquiry, this little patient had already been home for eight weeks. We succeeded, however, in obtaining fecal specimens from the patient during the tenth week and also from the two other children in the family. All were positive culturally for the *B. dysenteriae* of Sonne.<sup>16</sup> We could not explain, however, to our own satisfaction, the interval between the discharge of this little girl (October 18) and the occurrence of dysentery in the other children during the latter part of December. We felt that other cases must have filled the intervening

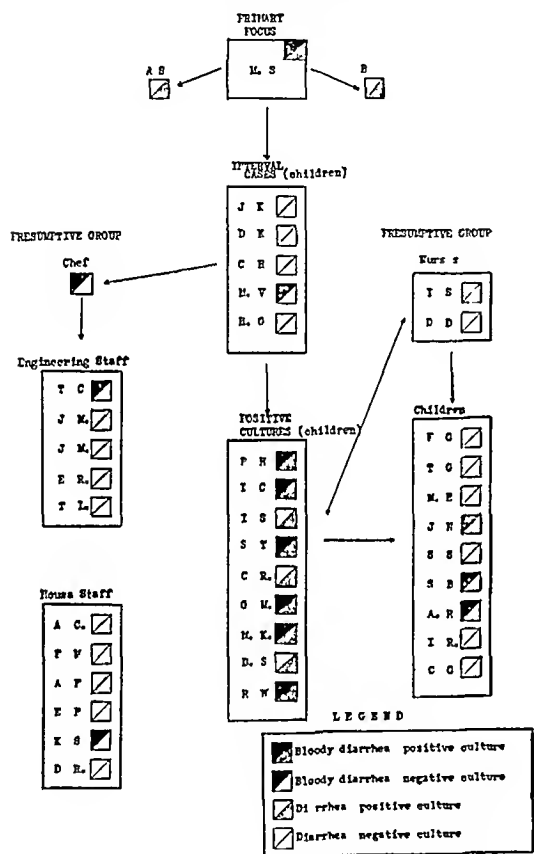

Chart 1—Epidemiologic survey of an outbreak of Sonne dysentery

cannot predicate our statement on actual cultural and serologic proof, since we learned of the adult cases too late to permit of accurate study. Moreover, the bacterial and agglutination criteria of Sonne dysentery are very transitory and irregular, as pointed out by MacGill and Downie, and do not appear to be related to the severity of the disease. Fraser, Kinloch and Smith<sup>13</sup> made similar observations and paralleled their observations with the clinical aspects. It might be added that the adult cases were erroneously regarded as due to "food poisoning," and the symptoms were believed to have occurred shortly after the evening meal. The two patients who showed ulcerative lesions by sigmoidoscopy belong to this group.

Among the children, the following case is of interest.

CASE 8—C. R., aged 5 years recuperating from an injury but feeling perfectly well otherwise, gradually developed a marked apathy and anorexia. At about the same time there occurred a rise in temperature to 101 F and on this day there

16 We could not definitely ascertain the source of infection in the child who served as the focus of dissemination. Both parents proved negative on repeated examination. The father, however, who was a traveling salesman had experienced a bloody stool four months previously which he had attributed to hemorrhoids. There were no domestic animals in the family and no relatives affected nor had the child been away from home.

gap and accordingly had the charts for all children admitted to the hospital from October 15 to December 15 reexamined and were rewarded by discovering five obvious cases of dysentery from November 3 to December 15. One of these children, M. V., had had a bloody diarrhea.

The ward was quarantined and we commenced an intensive survey of the nursing staff, kitchen help, engineering staff and all possible contacts. Cultures were taken of all food, both boiled and unboiled. The one kitchen suspect was relieved of responsible duties. The results of these studies may be summarized as follows:

Eleven children showed positive cultures for *B. dysenteriae* Sonne. Eight other children, three of them having had bloody stools, were diagnosed clinically as having bacillary dysentery, even though we could not prove it either by cultural or by agglutination tests. The probability of accurate diagnosis in this group on clinical evidence alone is apparent, however, from certain known facts already mentioned with regard to the Sonne type of dysentery. Similarly, fifteen members of the engineer's staff fell in the same group, i. e., culturally and agglutination free, except for a questionable organism in one case. Two of this group had bloody diarrhea and of these, one (K. S.) showed several superficial small follicular healing ulcers at the recto-sigmoid. Another (J. M.), who had not noted any blood in the diarrheal stool, showed two follicular lesions, one surrounded by an inflammatory vascular caput medusae. Two nurses in the children's ward had had diarrhea and could with reasonable certainty be included in the presumptive group. The member of the kitchen staff who had had a severe diarrhea was similarly classified. All of these cases occurred between December 18 and January 4, except the interval group, which covered the period between the first case (M. S.) in October and the time the outbreak was recognized in the latter part of December. Through proper isolation measures further spread of the disease was prevented, and by the end of January the outbreak was definitely terminated. The total number of persons involved was forty.

The short and relatively mild course of the disease and the limited period during which cultural and agglutination studies proved to be positive account for the fact that many of these cases were unrecognized, even when hospitalization took place before the inception of the disease, as occurred at the Bronx Hospital. It is of interest to note that at the time of this outbreak it was ascertained that a similar condition appeared to prevail at other hospitals in this section of the city. The clinical aspects were very similar to those described in this paper. The transitory and relatively benign character of the Sonne dysentery in our patients is evidenced by the fact that in some children the diarrhea lasted only from twenty-four to forty-eight hours and in none was it accompanied by any marked constitutional symptoms, by dehydration or by more than a slight rise in temperature. It is quite probable however, that in epidemic form the clinical and laboratory picture might be intensified, the virulence being enhanced by repeated passage through many human contacts. The mildness of the disease and missed cases in the outbreak reported brings up the question of the carrier problem. Ritchie, in a study of 792 normal serums, found that 30 per cent agglutinated Shiga strains in a dilution of 1:32, and that 41 per cent agglutinated Flexner strains in a dilu-

tion of 1:64 and 30 per cent in 1:128. This does not appear to be true for *B. dysenteriae* Sonne, but an increased incidence of the disease in this country may alter this fact.

We were able to make a sigmoidoscopic study of only a limited number of adults in the presumptive group (diarrhea with or without blood). Two cases showed ulceration of the mucosa with inflammatory reaction. In most of the cases with positive cultures there was probably only a reddening of the mucosa or very superficial and slight ulceration to account for the bleeding. We predicate this assumption on the experimental data in rabbits. We injected rabbits intravenously with pure cultures of the Sonne organism recovered from our cases. In some of the animals it took as much as 8 cc of a heavy suspension to produce diarrhea, and the organisms were recovered in the animals' feces. Post-mortem examination revealed only a slight edema of the intestinal mucosa, localized patches of hyperemia (chiefly in the colon), but no ulceration. These results were confirmed by microscopic section. It is of interest to note that almost all the rabbits survived the heavy inoculations, it being necessary to kill them for the pathologic studies. Their survival corresponds to the mild clinical course observed in our studies. Flexner in 1906 called attention to the fact that in bacillary dysentery the intestinal lesions are due to the excretion of dysentery toxin through the bowel wall rather than to any local action of the bacteria. He was able to produce the characteristic intestinal lesions in rabbits by the intravenous injection of the toxic autolysate. Experimentally, we may state that in the Sonne organisms studied by us neither the toxin nor the bacillus produced ulcerations in the rabbit's bowel, though the organisms injected intravenously were recovered in the feces. It is quite probable that the mucus observed in the stools in all our diarrheal cases was sufficient to protect the mucous membrane of the intestine against the relatively nontoxic Sonne strain.

#### CULTURAL, IMMUNOLOGIC AND ANIMAL STUDIES

*Method of Isolating Organisms*—Fresh fecal suspensions were streaked on Endo plates and incubated overnight. When the presence of colorless colonies typical of the typhoid-dysentery group were noted, single colonies were restreaked on this medium. After we confirmed the presence of the suggestive organisms, single colonies were inoculated into sterile broth ( $p_H$  7.8). From these broth cultures inoculations were made on Russell double sugar and plain agar slants ( $p_H$  7.4). Although the combined use of these differential mediums allowed for tentative classification of the organisms among the typhoid-dysentery group, more extensive fermentation tests were carried out.

*Fermentation Tests*—Inoculations were made into sterile broth containing 2 per cent of the specified carbohydrates with litmus as an indicator. One-tenth cubic centimeter of an eighteen hour culture was used as the inoculum for each tube and readings were taken after forty-eight hours' incubation. The tubes were replaced in the incubator because it was noticed that some of the strains produced acid in lactose after prolonged incubation (delayed lactose fermentation). This characteristic was not constant. Tests for indole production were made in peptone water cultures that had been incubated for five days.

*Morphology*—The organisms are short bacilli, 3 microns in length and 0.5 micron in width, with parallel sides and rounded edges. There was a slight variation

from this modal form in some of the cultures but not to any great degree. None of the organisms are motile and all are gram negative.

**Type of Growth**—The organisms grow well on all ordinary mediums. Twenty-four hour cultures on agar plates of all the isolated strains vary but slightly from the following description. The colonies are circular, raised, convex, smooth and colorless. They are about

TABLE 1—Cultural Characteristics of Organisms Isolated from Positive Cases (Sonne Dysentery)\*

Patient	Endo Plate	Motility	Russell's Double Sugar	Dextrose	Galactose	Lactose	Maltose	Mannite	Salicin	Sucrose	Indole
P H	+	0	Acid Butt	A	A	0	A	A	0	0	0

R W	+	0	Acid Butt	A	A	0	A	A	0	0	+

\* The colonies on twenty-four hour agar plates measure from 1 to 3 mm and are circular, raised, convex, smooth and colorless. The organisms are short, Gram negative bacilli with parallel sides. Variations in indole production by *B. dysenteriae* Sonne have been noted by many investigators. A denotes acid.

from 1 to 3 mm in diameter and have a butyroid consistency. There is a slight tendency to roughness, which is lost in a few transfers. In broth, there is usually an abundant growth with uniform turbidity.

About thirty organisms that were isolated from patients were tested. However, many of them which were not included in table 1 gave late fermentation of lactose with the production of gas. The other sugars showed early formation of acid and gas. These strains, which were gram negative, showed the presence of a capsule, and because of their action on the carbohydrates we concluded that they were *Bacterium aerogenes*. The organisms listed in table 1 gave uniform reactions in the sugars, except for one detail: a few of them, after prolonged incubation, showed a slight acid production in lactose. This was not noted in all the strains and the acid production was not very strong. Otherwise the strains all fermented dextrose, galactose, maltose and mannite with the production of acid.

With these data in hand we were able definitely to include these organisms among the dysentery group. To determine which member of this group was involved, we decided to study the organism serologically. Because of the mannite fermentation and the irregular indole production, we thought the causative agent belonged to the Flexner type of dysentery organisms.

#### AGGLUTINATION STUDIES

**Preparation of Immune Serums**—Rabbits were immunized to the following organisms: *B. dysenteriae* Shiga, *B. dysenteriae* Flexner Y, *B. dysenteriae* Sonne, *B. dysenteriae* Mount Desert, and the organism isolated from patient I C. Eighteen-hour agar cultures were emulsified in 0.85 per cent saline solution and the emulsions were treated with 0.5 per cent solution of formaldehyde. The formaldehyde-treated suspensions, tested for sterility, were injected into rabbits on three successive days. The animals were allowed to rest four days

and the immunization process was repeated. After each rabbit had received a total of twelve injections, seven days elapsed before a trial bleeding was resorted to. When the serums contained antibodies to sufficiently high titer, the rabbits were bled to death from the carotid artery.

**Agglutination Tests**—Serial dilutions of the serums were made and to 0.5 cc of the diluted serum, 0.5 cc of an eighteen-hour broth culture ( $pH$  7.0) was added. Suitable controls were used and the mixtures were incubated at from 52 to 55°C for four hours. Readings were taken and the tubes were refrigerated overnight. Final readings were taken after the tubes had been placed in the refrigerator overnight.

Using the immune serums obtained by the methods described, we performed agglutination tests with all the suspected organisms with the results listed in table 2.

In each case, agglutination with the anti-Sonne serum gave the highest titer and most consistent results. That some degree of agglutination did occur with the other serums can best be explained only by the heterogeneity of the dysentery group of micro-organisms fermenting mannite. This heterogeneity is manifested in the agglutination of *B. dysenteriae* Sonne with the anti-Flexner and anti-Shiga serums. The titer in this group agglutination is not as high, however, as with the homologous organism. From these agglutination and fermentation reactions, we felt justified in concluding that the organism we were dealing with was *B. dysenteriae* Sonne.

Of further interest are the results of the cross agglutination obtained with these strains. It shall suffice to state that serum obtained from patient P H was able to agglutinate the strain isolated from G M to a titer as high as 1:400. Further, a serum obtained by immunizing a rabbit with the strain from G M was able to agglutinate all the other strains listed in the table. All

TABLE 2—Agglutination Tests with Organisms Isolated from Positive Cases\*

Patient	Immune Serums			
	Anti Shiga	Anti Flexner	Anti Sonne	Anti Mount Desert
P H	0	0	1:320	0
I C	0	0	1:320	1:50
I S	1:160	1:160	1:320	1:100
M S	1:160	1:40	1:320	
S T	1:320	0	1:640	
G M	0	0	1:640	
B S	1:20	1:40	1:640	1:200
C R	0	0	1:320	
M K	0	0	1:320	
B S	0	0	1:320	
R W	1:40	1:20	1:640	

\* This table shows the agglutination titers reached by the patient's organism in the presence of the known serums. The numbers represent the highest dilution of the serum in which complete agglutination occurred.

the strains were agglutinated to practically the same titer. When one organism is agglutinated by a serum prepared against another organism and when the process can be reversed with similar results, these two agglutination tests constitute the "mirror test." This test is used to establish definitely the identity of two or more strains. The fact that we were able to perform this "mirror test" with all our strains greatly strengthens our conclusion that all the strains listed in table 2 were *B. dysenteriae* Sonne.

In a previous section we mentioned certain strains which were isolated and which because of their actions

on sugars we identified as *Bacterium aerogenes*. We attempted to agglutinate these strains with the known antisera, but in no case was any clumping perceptible. These tests thus served as suitable controls for the other strains and provided a clear-cut differentiation between the *B. dysenteriae* Sonne organisms and *Bacterium aerogenes*.

**Pathogenicity**—Live cultures of the Sonne organisms recovered from the patients were injected into rabbits with the following results:

**RABBIT 1**—Injected intravenously with 4 cc. of a forty-eight hour culture of strain G M. Twenty-four hours later the rabbit showed a profuse bloody diarrhea and the injected organism was recovered from the fecal material. The rabbit was killed two days after the injection and the gastro-intestinal tract was searched for ulcers. None were found.

**RABBIT 65**—Injected intravenously with 2 cc. of an eighteen hour culture with strain G M. The next day the animal showed signs of diarrhea. This rabbit lived for weeks after the injection, but a fecal culture seventy-two hours after the injection yielded strain G M.

**RABBIT 78**—Injected intravenously with 2 cc. of an eighteen hour culture of strain G M. In forty-eight hours after the injection there were signs of collapse and bloody diarrhea. The animal was killed three days after the injection and although the feces contained the injected organism, no evidence of ulcer formation could be seen.

**RABBIT 7**—Injected intravenously with 8 cc. of an eighteen hour culture of strain B S. A profuse diarrhea ensued and culture of the intestinal contents yielded the injected organism.

Chart 2—Antigenic heterogeneity of mannite fermenting group of dysentery organisms. This shows the heterogeneity of the Flexner group and the presence of all the antigenic factors in Flexner Y. The presence of *B. dysenteriae* Sonne antigen in all the Flexner strains demonstrates the possibility of agglutinating *B. dysenteriae* Sonne in immune Flexner serum. The reverse however is not possible.

The rabbit died in twenty-four hours and postmortem examination showed a hyperemia and congestion of the small and large intestine. No ulcers were seen.

**RABBIT 13**—Injected intravenously with 4 cc. of an eighteen hour culture of strain B S. The animal died in twenty-four hours with a profuse diarrhea. Intestinal ulcers could not be found, but the strain injected was recovered from the feces.

Attempts to reproduce the disease by feeding live cultures were repeated without success. This confirms the well known fact that bacillary dysentery cannot be reproduced experimentally in animals by oral administration of the causative organism.

#### CONCLUSIONS

1 Sonne dysentery chiefly affects children and is characterized by a short incubation period, brief course and general mildness.

2 The disease exists in endemic and epidemic form in the United States.

3 With increasing incidence it is expected that the general character of the disease will change and, in epidemic form, affect more adults and cause a higher degree of mortality in children.

4 Sonne dysentery is a contact infection and outbreaks can be terminated by proper epidemiologic measures.

5 The effects of high titer serums in patients and of specific vaccines in contact cases are now being studied.

## THE DIAGNOSIS AND TREATMENT OF PULMONARY ABSCESS IN CHILDREN

DAVID T. SMITH, M.D.

DURHAM, N. C.

Pulmonary abscess is not diagnosed as frequently in children as in adults probably because it occurs less commonly and is more difficult to differentiate from other pulmonary infections. Among 2,250 cases of lung abscess collected from the American literature, only fifty-nine were in infants and children.<sup>1</sup> Unquestionably the disease occurs more often than these figures indicated, since a majority of the clinics reporting cases did not treat children. Among 2,119 patients admitted to the pediatric service of the Duke Hospital seven had pulmonary abscess. An analysis of 172 consecutive cases of lung abscess by Flick and his co-workers<sup>12</sup> showed 64 per cent in the first decade, 10.5 per cent in the second, 27.9 per cent in the third, 30.8 per cent in the fourth, 18.6 per cent in the fifth, 3.6 per cent in the sixth and 2.3 per cent in the seventh decade of life.

Multiple embolic abscesses of the lung, which present themselves during a general septicemia, are regarded as an integral part of the septic disease and will not be discussed in this article.

The thirty-nine cases collected from the literature, supplemented by six previously reported from the Duke Hospital,<sup>2</sup> have been analyzed for predisposing causes. Among these forty-five cases twenty-four followed pneumonia, thirteen followed tonsillectomy, one followed aspiration of a foreign body, one followed exposure, and one followed aspiration of a membrane in a case of Vincent's angina.

There are four possible routes by which the infecting material may reach the lung. It may be introduced directly by a penetrating wound, it may drain in through the lymphatics, it may enter through the blood stream as an embolus, or it may be aspirated. There was no evidence in any of the cases studied that the material entered by either of the first two routes. Cutler and his co-workers<sup>3</sup> believe that most, if not all, of the abscesses following operations are embolic in origin. Certainly those following aspiration of a foreign body must reach the lungs through the air passages and those that follow pneumonia are logically explained by the same mechanism. Abscesses that follow operation in sterile fields, which remain sterile, are best explained by the aspiration of infected material while the patient is under an anesthetic. It is my opinion that the majority of the cases which follow operations on the tonsils and other structures in the upper respiratory tract are also due to simple aspiration.

The facility with which material from the mouth and pharynx is aspirated into the lungs has been demonstrated in the past few years by numerous investigators. Mullins and Ryder,<sup>4</sup> Corper<sup>5</sup> and Lemon<sup>6</sup> have shown that normal unanesthetized rabbits readily aspirate foreign material from the pharynx into the lungs when held on their backs with the head elevated. By bronchoscopic examination immediately following tonsillectomy under general anesthesia, Myerson<sup>7</sup> has demonstrated blood below the vocal cords in 76 per cent and the Dailys<sup>8</sup> in 78 per cent of the patients examined. Aspiration may occur even when the tonsils are removed under local anesthesia. Ochsner and Nesbit<sup>9</sup> found that every patient with local infiltrative anesthesia aspirated iodized oil while attempting to swallow, and Iglauer<sup>10</sup> noted blood in the trachea in 38 per cent of patients whose tonsils had been removed under local anesthesia. Hamilton<sup>11</sup> observed aspiration of iodized oil in two patients asleep from the effects of an opiate and in one patient in a normal sound sleep.

In children as in adults, pulmonary abscesses can be divided on the basis of etiology into (1) bacterial abscesses (2) fusospirochetal abscesses and (3) fungous abscesses. Kline<sup>12</sup> believes that the term abscess should be reserved for the bacterial type and that the fusospirochetal type should be designated as pulmonary gangrene. There is much to be said in favor of this view. As a rule the bacterial abscesses are not gangrenous while the fusospirochetal abscesses, whether diffuse through one or more lobes or limited to a small area in one lobe, are always gangrenous. The exceptions in this classification would be, first, the bacterial abscesses due to colon bacilli which give foul sputum without the lung being gangrenous and, second, the bacterial abscesses caused by *Clostridium welchii* and other gas gangrene bacilli in which the lung is gangrenous. I prefer to use the word abscess in its descriptive pathologic sense and preface it with the name of the specific etiologic agent. Thus one may speak of a staphylococcal abscess of the lung, an actinomycotic abscess of the lung or a fusospirochetal abscess of the lung. The reason for including the fusospirochetal infection as a specific etiologic unit will be discussed later.

#### BACTERIAL ABSCESS

Any pathogenic bacterium that gains access to the lungs may cause an inflammation and infiltration of the pulmonary tissues, but the ability to initiate abscess of the lung is limited to those organisms which produce proteolytic or necrotizing enzymes. The common bacteria that produce abscesses are staphylococci, Friedlander's bacilli, certain streptococci, *Bacillus pyocyaneus*, *Bacillus influenzae* and the members of the gas gangrene group of bacilli. When careful bacteriologic

studies have been made in a sufficient number of cases of pulmonary abscesses in children for one to speak in terms of statistics, I believe the staphylococci will be found to be the etiologic agent in at least 75 per cent of the bacterial type of abscess and in 50 per cent of all abscesses in children.<sup>13</sup>

#### FUSOSPIROCHETAL ABSCESS

In 1867 Leyden and Jaffe<sup>13</sup> found spirochetes in the sputum and in the lungs of adults with pulmonary abscesses. Jaffe is quoted by Miller<sup>14</sup> as having obtained in 1886 "progressive contraction of the trachea and real pulmonary abscess following introduction into the lungs of rabbits of shreds and casts from the mouth." Rona<sup>15</sup> in 1905 observed both fusiform bacilli and spirochetes in pulmonary gangrene. Buday<sup>16</sup> in 1910 described in detail the pathologic changes in thirty-five cases of pulmonary abscess and gangrene and demonstrated by stains the presence of fusiform bacilli, spirochetes, vibrios and cocci in the tissues.

With fusospirochetal material from the sputum, the gums or the tonsils of patients I have produced pulmonary abscesses in mice,<sup>17</sup> in guinea-pigs<sup>17</sup> and in rabbits.<sup>18</sup> They have been produced in rabbits by Kline<sup>19</sup> and in dogs by Crowe and Scarff,<sup>19</sup> Allen,<sup>20</sup> Hedblom, Joannides and Rosenthal,<sup>21</sup> Harkavy,<sup>22</sup> Van Allen, Adams and Hrdina,<sup>23</sup> and Herrmann and Cutler.<sup>24</sup> This uniform series of successful experiments leaves little doubt that the fusospirochetal mixture is pathogenic, but it does not prove which organism or combination of organisms is responsible for the disease.

I have isolated the following organisms in pure culture from patients with fusospirochetal pulmonary abscesses: *Treponema microdentatum*, *Treponema macrodentatum*, *Treponema buccale*, *Vibrio viridans*, *Bacterium melaninogenicum*, *Micrococcus gazogenes*, a large fusiform bacillus, a small fusiform bacillus, alpha, beta and gamma strains of streptococci and the several types of staphylococci.<sup>25</sup> Cultures of *Treponema vincenti* and *Spirillum sputigenum* were grown in symbiosis with cocci but never isolated in pure culture. Some of these cultures were isolated from children and some from adults.

Several of the strains of streptococci produced fatal cellulitis and pneumonitis and some of the staphylococci initiated small, nonfatal abscesses, but none of the other organisms produced infection. Spirochetes, alone or mixed with fusiform bacilli, failed to infect mice, guinea-pigs or rabbits. Although the pure cultures

failed to reproduce the disease a mixture made from pure cultures of *Treponema microdentatum*, *Vibrio viridans*, a small fusiform bacillus and a beta hemolytic streptococcus produced a typically foul necrotic abscess, which could be transmitted to animals in series.<sup>24</sup> The spirochete is an essential element in this symbiosis and the disease could no longer be transmitted from animal to animal if the spirochete disappeared either spontaneously or as a result of arsenic therapy even though all the other organisms were present. Herrmann and Cutler<sup>24</sup> failed to produce chronic fetid abscesses in dogs with pure cultures of any one of the twelve types of organisms isolated from pulmonary abscesses but succeeded with a mixture of the anaerobic forms. The recent work of Proske<sup>25</sup> has confirmed and extended the evidence I<sup>26</sup> have obtained and that presented by Herrmann and Cutler, attesting that this disease is caused by a symbiosis of non-spore-bearing anaerobic organisms.

The source of this mixture of organisms which is responsible for the fusospirochetal type of abscess is generally the gums or the tonsils of the patient although occasionally it may be contracted from another individual.<sup>25</sup>

#### MYCOTIC ABSCESS

In adults, abscess of the lung may be caused by any one of the organisms listed in the accompanying table. I have seen one child infected with sporothrix and one with actinomycetes. Proof of their relation to the disease rests primarily on the presence of the organism in the lesion and on certain immunologic and serologic reactions such as skin tests, agglutinations and complement fixations.

#### DIAGNOSIS

The history of a tonsillectomy or aspiration of a foreign body should at once direct the attention to the possibility of a fusospirochetal abscess, although in one previously reported case the aspiration of an oat head was followed by an actinomycotic abscess of the lungs.

A child with the clinical signs and symptoms of pneumonia who has gingivitis or Vincent's infection of the tonsils may have a fusospirochetal abscess of the lungs. I have seen two such cases in infants in whom the treatment was delayed until the diagnosis was made by pleural tapping, both patients died.

The history, physical signs and x-ray shadows may be identical in cases of bacterial abscess, fusospirochetal abscess and mycotic abscess. The final diagnosis rests entirely on a study of the pulmonary secretions. Sputum is more difficult to obtain in children than in adults and recourse to laryngeal swabbings, bronchoscopic drainage and pleural tapping may be necessary. Exploring the lung with a needle in search of an abscess is contraindicated because of the danger of producing empyema.

The common bacteria that produce lung abscess are easily cultivated on blood agar. The spore bearing anaerobes of the gas gangrene group may be demonstrated by the Gram stain and cultivated in tubes of meat or milk mediums sealed with sterile petrolatum or on the surface of blood agar plates incubated under anaerobic conditions.

The fusiform bacilli and the thicker spirochetes (*Treponema buccale* and *Treponema vincenti*) are

readily demonstrated by staining a smear of the secretion with gentian violet or dilute carbol-fuchsin. The finer spirochetes (*Treponema microdentatum* and *Treponema macrodentatum*) may be shown by the Fontana stain or by the darkfield apparatus. When chunks of purulent sputum can be obtained, the smears should be made from the pus in the center. If no large particles are found, it is difficult and at times impossible to learn whether the fusiform bacilli and spirochetes are from the lungs or merely contaminants from the mouth. In infants, I believe it is wiser to assume that the organisms are from the lungs and to proceed with specific treatment.

Cells of the yeastlike and moldlike fungi may be found by direct microscopic examination after the material has been treated with a 10 per cent solution of sodium hydroxide. The higher bacterial forms may be found in fresh preparations as "sulphur granules" or demonstrated in stained smears as branching gram-positive rods and filaments. Some of the nocardia or streptothrix organisms are non-acid fast and some acid fast. Sometimes it is necessary to inoculate a guinea-pig to prove that these acid-fast forms are not atypical tubercle bacilli.

#### Fungous Diseases of the Lungs

I	Yeastlike Fungi
1	Saccharomyces
2	Monilia
3	Torula
4	Endomyces
5	Geotrichum (Oldium)
6	Blastomyces
7	Coccidioides immitis
8	Sporothrix
II	Moldlike Fungi
9	Aspergillus
10	Penicillium
11	Mucor
III	Higher Bacterial Forms
12	Actinomyces
13	Nocardia (a) acid fast (b) nonacid fast

Often the greatest difficulty is encountered in distinguishing pulmonary abscess from (1) pulmonary tuberculosis, (2) encapsulated and interlobar empyema and (3) unresolved pneumonia, yet it is absolutely necessary to make a specific diagnosis if specific treatment is to be applied.

#### TREATMENT

The general supportive measures, such as rest in bed, forcing of fluids, high vitamin diet and postural drainage, can be applied equally well to all types of pulmonary abscess.

If the bacterial abscess is caused by an organism of the gas gangrene group, the patient should be treated with specific or polyvalent antigangrene serums. The acute staphylococcal abscesses might be treated with the new staphylococcus antitoxin, which I among others have found to be polyvalent and to protect rabbits against staphylococcus toxin formed by organisms isolated from different patients.<sup>29</sup> I have not as yet had an opportunity of treating a primary pulmonary infection with this antitoxin. Abscesses due to the other bacteria should be treated palliatively in the acute stage unless empyema develops. In the subacute stage postural drainage, bronchoscopic drainage and perhaps autogenous vaccine therapy is indicated. If the lesion persists for three months, it has reached the chronic

<sup>26</sup> Smith, D. T. Fusospirochetal Disease of the Lungs Produced with Cultures from Vincent's Angina. *J. Infect. Dis.* 46: 303 (April) 1930.

<sup>29</sup> This investigation has been conducted by Joyner, Rigdon and Hare and will soon appear in the literature.

stage and should be treated by open operation and drainage

The fusospirochetal type of pulmonary abscess should be diagnosed and arsenic treatment started within the first two weeks of the disease if the best results are to be obtained. Either nearsphenamine or sulpharsphenamine may be used in doses about one half as large as a similar child would require for syphilis, but repeated every three or four days up to six or eight doses. Bronchoscopy should be employed if postural drainage is not effective. Phrenicectomy is not advised, because of the danger of kinking the bronchus and stopping the drainage. Artificial pneumothorax is inadvisable for the same reason and because of the danger of causing the abscess to rupture into the pleura, initiating a severe if not fatal empyema. In cases in which the lesion persists for three months while the patient is receiving arsenic therapy, postural drainage and bronchoscopic treatment, the abscess is chronic and should be drained by open operation.

The mycotic abscesses of the lung should be treated by gradually increasing doses of potassium iodide. If the patient does not respond to this treatment, it should be supplemented by inhalations of ethyl iodide with an initial dose of from 0.5 cc to 1 cc once daily, gradually increased to 2 cc three times daily. Vaccine therapy seems to be of value in some cases as a supplementary treatment.

#### SUMMARY

An effort should be made to determine the etiology of every case of pulmonary abscess occurring in children, because those initiated by the gas gangrene anaerobes can be treated with specific antitoxin serum, those due to the fusospirochetal organisms can be treated with nearsphenamine or sulpharsphenamine, and those caused by fungi respond to potassium iodide or ethyl iodide therapy.

#### ABSTRACT OF DISCUSSION

DR LOUIS H. CLERF, Philadelphia. Dr Smith's presentation on pulmonary abscess in children has brought out some important points. Pulmonary abscess in children is more common than is generally realized. Many of the patients that I have seen were treated as cases of pneumonia for a considerable time. One wonders how many of the cases that recovered spontaneously from abscess were diagnosed as pneumonia. Although much of the experimental evidence indicates that abscess of the lung may be embolic in origin, I am of the opinion that aspiration plays a very important part. I have often marveled that one could indicate on the basis of physical examination and roentgen study that a single abscess in a given case was of embolic origin. To me clinical evidence supports aspiration. I agree with Dr Smith that the designation "abscess" is preferable to pulmonary gangrene if the lesion consists of a localized collection of pus in a cavity formed by the disintegration of tissues. The term "gangrene" as commonly employed implies more than a localized process. The etiologic organism, so far as the production of an abscess is concerned, is obviously difficult to determine. In a majority of the cases observed by me a number of organisms were found. However, if one does a bronchoscopy early, before the area of pneumonitis has gone on to abscess formation, one may secure organisms in pure culture from the secretion removed. In four cases so examined a streptococcus was found in pure culture. Diagnosis of pulmonary abscess is difficult in the early stages at a time when treatment should be instituted if the best results are to be secured. A lesion localized to one lobe, occurring within a week or ten days after an operation, particularly tonsillectomy, is very probably a pneumonitis which will either clear up spontaneously or go on to abscess formation. My concept of pulmonary abscess presupposes the existence of an inflammatory lesion that has broken down

I agree that arsenical treatment is of value in the fusospirochetal type of abscess and should be administered early if good results are to be secured. I consider it of little value in long standing cases. In my experience, operations, particularly those about the mouth and throat, have figured in approximately 70 per cent of the cases of pulmonary abscess that came under observation. A diagnostic bronchoscopy is indicated in all these cases unless there is a very definite contra-indication. I believe that it is a mistake to delay until there is a definite abscess cavity with fluid level before one will make a diagnosis of pulmonary abscess and then consider appropriate treatment. Early bronchoscopy in a number of these cases of so-called pneumonitis, a pulmonary lesion which I believe precedes the formation of abscess, has been followed by prompt clearing of the lesion. If this is done, many potential cases of abscess will be cases of acute pneumonitis with spontaneous recovery.

DR J. W. EPSTEIN, Cleveland. In our studies of pulmonary gangrene and pulmonary abscess at Mount Sinai Hospital we classified these conditions to conform with their clinical and pathologic characteristics. Dr B. S. Kline, director of our laboratories, whose exhaustive studies and contributions on this subject are well known, is responsible for its terminology. The classification is as follows: 1. Embolic pulmonary abscess. 2. Bronchogenic pulmonary abscess. 3. Pulmonary gangrene. The embolic abscess occurs more frequently in infants and in children. These patients usually have a suppurative condition elsewhere in the body and their pulmonary lesion represents a manifestation of bacteremia. The bronchogenic pulmonary abscess is the type most frequently met in infants and children. By bronchogenic abscess we mean an area of suppuration in the lung caused by pyogenic organisms gaining access through the bronchus. They are therefore always aspiratory in character. Pulmonary gangrene is a distinct clinical entity and should not be confused with pulmonary abscess. Pyogenic organisms never produce gangrene, while the characteristic lesion caused by spirochetes fusiform bacilli and vibrios is not abscess but gangrene. Pulmonary gangrene is much more frequent than pulmonary abscess and is six times as frequent in adults as in children. In our series of thirty-nine cases of pulmonary gangrene, only seven were in children. The number of cases of pulmonary gangrene in children and adults treated in our hospital in a comparatively short period of time is convincing evidence that this disease is not of rare occurrence, yet its apparent frequency is not properly reflected in the number of reports appearing in the medical literature. Heretofore, the total number of cases of pulmonary gangrene reported in the United States has hardly reached a few hundred as compared to thirty-nine cases observed in one hospital. The discrepancy between the number of cases reported and the number that actually occurred leads me to believe that there is a great deal of confusion regarding these two clinical entities and that many of the cases reported as pulmonary abscess from clinical and roentgenographic evidence, but not supplemented by study of sputum, were actually cases of pulmonary gangrene. I therefore feel that the term "pulmonary gangrene," not "pulmonary abscess," should be applied to lesions caused by spirochetal anaerobes.

DR E. F. BUTLER, Elmira, N. Y. This discussion is from the standpoint of the thoracic surgeon, who may eventually be called on to treat some of these cases. In my experience about 10 per cent of all cases of lung suppuration occur in children. Fortunately the prognosis is good as compared to cases occurring in adults. The pediatrician has an important role to play. It is true that not every case of respiratory infection requires elaborate diagnostic study. However, in cases of recurrent infection or infection that continues without improvement for two or more weeks there rests on the pediatrician an obligation to arrive at an accurate diagnosis of the underlying pathologic condition. There should be a complete review of the history of the case with special reference to previous operations or the possibility of foreign bodies; there should be a complete review of the physical observations with special reference to changes in the upper respiratory tract; the bacteriologic examination should be exhaustively studied, as set forth by Dr Smith; roentgen examination should not only include an anteroposterior film of the chest but should also include

fluoroscopy and such lateral or oblique films as may be indicated, bronchoscopy is most valuable in these cases. Some men might be inclined to add exploratory aspiration as the next diagnostic step. Let it be emphatically stated that exploratory aspiration should not be performed in the presence of a suspected lung abscess or other pulmonary suppuration. There is no assurance that the aspirating needle will not traverse a clean defenseless pleural cavity and pave the way for a putrid empyema with an attendant mortality risk of from 75 to 90 per cent. There is no assurance that cellulitis of the chest wall may not result from such a procedure. It is safer to expose the diseased lung surgically and be assured of defensive pleural adhesions than to plunge a needle blindly through the chest wall. Therefore let it be said emphatically that the pediatrician or the general practitioner should not undertake exploratory aspiration under such conditions but should refer an uncomplicated case to a qualified thoracic surgeon.

DR DAVID T. SMITH, Durham, N. C. I agree with all the discussers in detail, except perhaps with the terminology used by Dr Epstein. I don't think it makes a particle of difference whether one wants to designate this peculiar type of abscess as a fusospirochetal abscess or as gangrene, as long as one knows what one is talking about. He prefers the term gangrene and there is a lot to be said for this view. I prefer the term abscess, and whether there is much to be said for it or not, it does not matter, as long as one recognizes that this is a particular type of infection. If diagnosed sufficiently early, it will respond to arsenical treatment.

## CYCLOPROPANE ANESTHESIA

RALPH M. WATERS, M.D.  
AND

ERWIN R. SCHMIDT, M.D.  
MADISON, WIS.

A new inhalation anesthetic agent is presented. To justify such a contribution, the drug must have advantages over the drugs in current use. We propose in this paper to present the results of a twelve months' clinical study of cyclopropane, including over 2,000 clinical administrations, leaving the reader to judge either the evidence warrants acceptance of this agent or in addition to the present therapeutic armamentarium.

John Snow was the first member of the medical profession to devote his attention to anesthesia. He was the first to appreciate the disadvantages as well as the advantages of ether as an anesthetic agent and he called attention to the unpleasant induction and recovery, difficulty of technique of administration and the irritation of the respiratory tract by that drug. He called attention to the safety of ether in comparison with chloroform through the improbability of causing primary cardiac damage by its use. Search for a drug that would not injure the heart but possessing the anesthetic properties characteristic of chloroform led him to study various hydrocarbons. One, amylene ( $C_8H_{10}$ ), he administered to 238 patients. Although Snow appreciated the physiologic importance of oxygen, it was not available in his time as a vehicle or adjuvant to narcotic drugs. His experience with gaseous hydrocarbons was therefore limited. Since the death of Snow (1858), many such gases have been studied. In this country, ethylene ( $C_2H_4$ ) alone has stood the test of time. Its usefulness has been limited, however, because of the lack of potency in concentrations that do not produce oxygen want.

In the search for new inhalation agents propylene ( $CH_3CHCH_3$ ) received extensive study. Electro-

cardiographic observations<sup>1</sup> showed certain cardiac irregularities and arrhythmias that seemed to condemn it for anesthetic purposes. Searching for the cause of cardiac damage in propylene anesthesia, Lucas and Henderson studied a possible contaminant or impurity, its isomer cyclopropane. This agent proved not to be the factor causing cardiac damage but to be a more potent anesthetic agent than propylene, causing very little change in the physiologic processes of laboratory animals. In addition, they found cyclopropane rapid in action, pleasant to inhale, of slight toxicity in effective concentrations, and susceptible of being rapidly eliminated.

A preliminary report on the first clinical application of cyclopropane was made by the Department of Anesthesia of the University of Wisconsin in October 1933.<sup>2</sup> Studies of the effects of this agent on various functions of animals have been reported from the laboratories of the University of Wisconsin Medical School.<sup>3</sup> In the present communication are summarized the clinical results from a year's routine use of cyclopropane in the various surgical services of the Wisconsin General Hospital, in comparison with ethylene on the one hand and ethyl ether on the other. The results of certain detailed studies of physical characteristics as well as physiologic effects are included, with a view to anticipating the reader's questions as completely as possible. All administrations included in the report were made by members of the anesthesia staff, graduates in medicine in various stages of training, ranging from interns serving one month in anesthesia through residents in the service for three year periods, and including the chief of the service.

The technique of administration used, with the exceptions noted, has been that known as the carbon dioxide absorption technique.<sup>4</sup> A closed extension of the respiratory tract is obtained by means of a mask, canister of soda lime granules, and breathing bag. Expired carbon dioxide is retained in the soda lime in the form of a carbonate. The oxygen used from the anesthetic mixture, filling such an enlarged respiratory system, is replaced by a constant metered flow of oxygen, approximately equal in quantity to that utilized by the patient. When endotracheal airways were used, they were sufficiently large to accommodate "to-and-fro" breathing<sup>5</sup> and were connected directly to the soda lime canister, thus replacing the face mask.

## PREPARATION, PHYSICAL PROPERTIES

The simplest cyclic hydrocarbon—cyclopropane or trimethylene—was first prepared by the chemist Freund<sup>6</sup> in 1882. No use was found for the agent and little concerning cyclopropane appears in the chemical or other literature until 1929, when Henderson and Lucas<sup>7</sup> published their studies. The method used in preparation has been the reduction of an alcoholic solution of

From the University of Wisconsin Medical School

trimethylene bromide in the presence of metallic zinc. The Ohio Chemical and Manufacturing Company has prepared the cyclopropane used as a basis for this report. As with the preparation of other hydrocarbons, purification of the product is important. The supply furnished the University of Wisconsin during the past year has been uniform and has remained stable while stored in steel cylinders for a period of twelve months, and no evidence of impurity has been observed. The containers caused some embarrassment at first because valve packing of the sort used in storage of ethylene and nitrous oxide was not efficient in forming a leak-tight closure of the cylinders. During the last nine months we have had no difficulty with leaking valves. The gas is liquefied at a pressure of 75 pounds per square inch. It is heavier than air (specific gravity 1.46) and the molecular weight is 42.05. Twenty-eight grams (1 ounce) of the agent is equivalent to approximately 16 liters (4¼ gallons) of gas at atmospheric pressure. The structural formula is  $\begin{array}{c} \text{CH}_2 \\ \diagup \quad \diagdown \\ \text{H} \quad \text{C} \quad \text{CH}_2 \\ \diagdown \quad \diagup \end{array}$ . According to Henderson and Lucas, it is practically insoluble in water but very soluble in lipoids, having a water-oil ratio of about 1:65. It is an inflammable agent, capable, in our experience, of exploding when mixed with oxygen in concentrations as low as 3.8 per cent.<sup>8</sup> Cyclopropane, ether and ethylene all form explosive mixtures with air and oxygen, making it necessary to take precautions against fire hazards when using one of these agents. Anesthetic mixtures are quite as likely to come in contact with the cautery, electric sparks from motors, and other sources of ignition, at varying distances from the mask or apparatus as they are to be exposed to such sources within the mask or breathing bag. Knowledge of the exact flash point, therefore, in the case of a given agent is of little importance. Unlike ethylene, which is somewhat lighter, cyclopropane and ether are heavier than air, and the precautions necessary for safety when using them are similar.

Cyclopropane is diffusible through rubber, as are ethylene, carbon dioxide and nitrous oxide.<sup>9</sup> An 8 liter rubber breathing bag, filled to capacity without pressure and containing by analysis 92.8 per cent of cyclopropane, 1.3 per cent of oxygen and 5.7 per cent of undetermined gas, after four hours and forty-five minutes was found to contain much less gas, and analysis showed 85.6 per cent of cyclopropane, 4.66 per cent of oxygen and 8.7 per cent undetermined. Eighteen hours and forty-five minutes after filling, analysis showed 60.0 per cent of cyclopropane, 13.8 per cent of oxygen and 26.4 per cent undetermined. The weight of such a bag filled with the gas decreased at a rate of 0.0876 Gm per hour, or 4.2 Gm in forty-eight hours. A bag placed over a frame to prevent collapse and attached to a water manometer reached a negative pressure of 24 cm of water in thirty hours, the negative pressure then decreasing slowly for several days. The rapidity of escape of cyclopropane through the skin during anesthesia has not been compared with other agents.<sup>10</sup>

#### EFFECTIVE CONCENTRATIONS

Cyclopropane is capable of producing narcosis when inhaled in a concentration as low as 4 per cent. Even lower concentrations have maintained a light degree of

anesthesia in patients who have received richer mixtures during the early stages of administration. It is therefore evident that anesthesia may be effected by inhalation of this agent with air as a vehicle. Insufflation into the pharynx of cyclopropane at a rate of from 200 to 800 cc per minute has maintained satisfactory anesthesia for abdominal surgery in the few cases in which it has been tried. The carbon dioxide absorption technic described has proved more satisfactory. With this technic, gas analyses have been made of the mask concentration coincident with various degrees of narcosis. For preanesthetic medication in all cases studied, morphine from 0.008 to 0.016 Gm (⅛ to ¼ grain) and scopolamine from 0.00032 to 0.00065 Gm (⅓<sub>200</sub> to ⅓<sub>100</sub> grain) was administered hypodermically about one and one-half hours before induction.<sup>11</sup> Forty-six cases have been selected from this group for graphic compilation (fig. 1), in which a definite statement was possible as to the plane of anesthesia<sup>12</sup> at the time of sampling and in which no change in the mixture had been made for five or more minutes. The graphs show concentrations of cyclopropane found by analysis of the mask contents for each degree of narcosis. In the upper circles are shown the maximum percentages found in any one sample; in the lower circles the minimum, and averages for all analyses in the large circles. Determination of oxygen and carbon dioxide was also made. The oxygen figures are included in the graphs. It will be seen that the average concentration of cyclopropane for first plane, third stage anesthesia (roving eyeball) was 7.4 per cent, while second plane (fixed eyeball) sufficient for a majority of abdominal operations) required an average of 13.1 per cent, and third plane, with intercostal paralysis, required an average of 23.3 per cent. In our experience the fourth plane, as noted later, cannot be separated from the third. Fourth stage anesthesia, or respiratory arrest, was produced with an average concentration of 42.9 per cent. When produced in the presence of high oxygen concentrations, such respiratory arrest has not been found to cause harm provided ample tidal exchange is artificially maintained.

It will be noted in the graphs that oxygen always exceeded 20 per cent. The intention in each case was to fill the respiratory spaces with a cyclopropane-oxygen mixture. Since the maximum carbon dioxide content of any sample was less than 4 per cent, it will be seen that a residue of nitrogen was present in every sample in quantity varying over a wide range. This nitrogen was derived in part from the air present in the patient's air passages when the mask was originally applied and in part from the desaturation of the patient's tissues and blood during anesthesia. This fact must be kept constantly in mind and care taken to maintain an oxygen content of decidedly more than 20 per cent.

#### TECHNIC OF ADMINISTRATION

Before we adopted the present technic, our tendency was to use too high a concentration of cyclopropane. This difficulty undoubtedly rose from our familiarity with nitrous oxide and ethylene, which require a concentration exceeding 75 per cent to be effective. The

<sup>8</sup> We regret that in a previous communication<sup>2</sup> from this institution a table of explosive ranges was published which gave incorrect figures.

<sup>11</sup> Seevers, Meek, Rovenstine and Sules<sup>3</sup> compared a group of dogs that had received similar premedication with a group uninfluenced by nonvolatile agents. They found an average difference in concentration of cyclopropane necessary to maintain a given degree of narcosis of about 12 per cent. For example if 18 per cent cyclopropane maintained first plane third stage anesthesia in a dog without premedication it required only 6 per cent to accomplish a similar result after premedication with morphine and scopolamine. There would appear to be a similar difference in dosage in patients.

<sup>12</sup> Classification of degrees of narcosis used is that of Cuedel (*Anesth. & Analg.* 6: 157 [Aug.] 1927).

method for satisfactory use of the completely closed carbon dioxide absorption technique is as follows. Administration is begun with a very rapid flow of oxygen (8 or 10 liters per minute) into the mask as it is placed on the patient's face and continued until the mask canister and bag are sufficiently filled to accommodate completely the patient's tidal excursion. At the same time, cyclopropane is introduced at a rate of 600 or 700 cc per minute in average cases and continued for from thirty seconds to two or three minutes. The addition of cyclopropane is then stopped completely. An interval of several minutes must intervene before complete distribution to the tissues takes place and maximum narcotic effects result. In certain resistant individuals it may be necessary to give the gas for a few seconds at a more rapid rate, and in some very susceptible ones, or those heavily dosed with non-volatile agents, a slower flow during induction is indicated.

During the period of maintenance, a constant slow flow of oxygen should be added, approximating as nearly as possible the metabolic demand of the patient. This usually varies between 250 and 400 cc per minute. An air-tight contact of the mask on the face simplifies maintenance of smooth anesthesia. A few minutes of observation usually suffices to determine the optimal constant flow of oxygen for a given patient. If physical signs indicate that the degree of narcosis resulting from the mixture originally used to fill the mask, canister and bag is insufficient, the flow of cyclopropane may be resumed for a time sufficient to enrich the mixture properly. If, on the other hand, the degree of narcosis is too profound as evidenced by physical signs, a rapid addition of oxygen for a brief period will reduce the potency of the mixture inhaled. The necessity for maintenance of unobstructed respiration is quite as important as with other agents. Pharyngeal airways are frequently used for this purpose.

#### PHYSICAL SIGNS

In general, the physical signs used in ether anesthesia, to determine the degree of narcosis present, are applicable. Cyclopropane, however, possesses two properties that are responsible for definite differences in physical signs and necessitate quite different interpretations from those commonly accepted for the older anesthetic agents.

First, although a gas like nitrous oxide and ethylene, cyclopropane is of the potency of chloroform and ether, but without their irritant qualities. Consequently, an extremely high concentration can be inhaled without producing laryngospasm, the normal physiologic protection from a sudden and extreme increase in dosage. Lacking this protection, the anesthetist experienced in the use of nitrous oxide or ethylene must guard against rushing the patient rapidly from one degree of narcosis to another and not allowing sufficient time for circulatory distribution and maximum effect of one concentration with full development of the physical signs characteristic of that dose. Second, cyclopropane is not a respiratory stimulant. As commonly administered ether, nitrous oxide and ethylene, on the other hand always tend to produce an initial increase in rate and minute volume respiration, up to the point at which the depression of an overdose or of oxygen want supervenes. In other words, they must be administered to a point of very large dosage before the respiratory rate and the minute volume decrease to normal. Cyclopropane if administered with oxygen as a vehicle and

without carbon dioxide excess, may result in no change in respiratory rate or minute volume until depressive doses are reached. The high oxygen concentration used may even result in reduced minute volume in the early stages of administration.

The disappearance of the lid reflex, which has been used since Snow's time to determine the degree of narcosis below which there is no pain perception, is a reliable. Complete extra-ocular paralysis, with cessation of movement of the eyeball and fixation in a "looking forward" position, was at first thought to occur relatively later than with ether. We are now inclined to believe that the better skeletal muscle relaxation due to better oxygenation in the first plane accounts for our early misinterpretation of this sign. With increasing experience, our reliance on the physical signs commonly used has increased. We are still unable, however, to discriminate between the third and fourth planes of third stage anesthesia. The patient in the first plane shows retained extra-ocular muscle activity. As the narcosis deepens and he reaches the second plane, movement of the eyeball ceases but both the diaphragm and intercostal

Fig. 1—Gas analyses of mask samples from forty-six cases taken during the various planes of surgical anesthesia and during the fourth stage (respiratory arrest). Upper circles show maximum cyclopropane concentration, lower circles show minimum, and large circles show the average percentage for each degree of narcosis.

muscles maintain their normal share of the load of respiration. As the depth of anesthesia increases still further, intercostal activity lessens, is delayed, and finally ceases as the patient passes into the third plane, characterized by diaphragmatic breathing only. Diaphragmatic breathing in plane 3, however, is not exaggerated during cyclopropane anesthesia as it is with ether. While the patient is passing down through this plane, depression simply increases until complete respiratory paralysis is reached, without evidence of a change from the third into the fourth plane. When respiration ceases, the patient, of course, may be considered in fourth stage narcosis.

#### PREMEDICATION

Our present attitude toward premedication with non-volatile agents in relation to cyclopropane is that respiratory depression by such drugs is to be avoided. Barbituric acid derivatives, tribrom-ethanol, opium derivatives, and certain other drugs commonly used in preliminary medication all tend to depress respiration and decrease minute volume exchange. Our best results

have been obtained by decreasing the dose of the opium derivative generally used before other agents by at least one half, while retaining the full customary dosage of scopolamine and giving them together about one and one-half hours preoperatively. This premedication would be entirely inadequate for ethylene or nitrous oxide administration. In the few cases in which anesthesia was induced with no premedication, the anesthesia was quite satisfactory although requiring a higher concentration for induction. A surprisingly slight stimulation of the salivary glands may be expected in such cases.

#### DANGER SIGNS

The pupils dilate sluggishly in morphinized patients and the sign is of little value. Color cannot be used as an indication of the degree of narcosis or of danger, because an excess of oxygen should be present and the patient decidedly pink at all times. The most valuable signs, warning that the limit of tolerance has been reached, are changes in the character of the pulse. Arrhythmia, slowing of the rate to 50 and less or a definite increase in rate demands a reduction in gas concentration by the addition of a considerable quantity of oxygen. Inflation of the lungs with oxygen is indicated if such pulse changes occur when respiration is decidedly depressed.<sup>13</sup> To the anesthetist experienced with other drugs, the addition of carbon dioxide is apparently indicated. However, we believe that carbon dioxide additions are definitely contraindicated. Instead, simple reduction of anesthetic concentrations should be practiced. When in doubt as to depth of narcosis, one should always add oxygen in cyclopropane anesthesia. The beginner's mistakes will always be in the direction of overdosage. Although the average concentration causing respiratory paralysis is 42.9 per cent, extreme respiratory depression may occur with as low a concentration as 21 per cent (fig. 1). It is scarcely conceivable that warning of impending cessation of breathing would not be taken from gradually increasing depression, unless a large quantity of the gas was suddenly added to the respiratory system either through lack of familiarity with the agent or by accident. Exception to this statement might be made in case of too large a dosage of a preanesthetic medicament and considerable respiratory depression before the mask was applied. Under such circumstances the induction should be conducted with a weak mixture of the gas. If the rule is always observed of maintaining a high oxygen content in the atmosphere inhaled, the advent of respiratory arrest need not cause alarm, since one or two inflations of the chest with oxygen or with a weaker mixture will always reestablish respiration. Removal of the mask without artificial respiration, in dogs, has many times resulted in spontaneous breathing and rapid recovery without untoward effects.

#### ABSORPTION AND ELIMINATION

The odor of pure cyclopropane is neither unpleasant nor irritating to the upper respiratory mucosa even in concentrations stronger than needed for anesthesia. Laryngospasm may result from extremely high percentages. It is evident, therefore, that the administration of a mixture containing 50 per cent of the gas might be accepted by a patient without coughing or holding the breath. Such an induction in dogs has

resulted in anesthesia in a very few breaths, quickly followed by respiratory arrest. Seevers, De Fazio and Evans<sup>14</sup> have compared the rate of absorption and elimination of cyclopropane with ethylene and find the former more rapid. The apparent slowness of induction seen in the technic described is explained by the very gradual increase in concentrations recommended. Such an induction we feel to be safer than a more rapid one when using an extremely potent agent. Gas analyses of gastric, peritoneal and subcutaneous gas pockets in animals have been found to contain increasing concentrations of cyclopropane as anesthesia is prolonged, approaching but not reaching, in the periods of anesthesia, the concentrations inhaled.

After administration, it is evident that desaturation of the body cavities as well as the tissues must take place over a considerable time. Gas analyses of gradually increasing low concentrations inhaled for the purpose of determining the minimum effective percentages lead us to believe that a normal individual is not affected by less than 3.5 per cent. The lowest concentration found in the mask during operation has been 3.8 per cent. If the mask is suddenly removed while the patient is inhaling a full anesthetic concentration of cyclopropane, he will sometimes pass through a period of excitation, whereas a gradual decrease in the concentration toward the end of an operation will result in a more nearly normal awakening. Gas analyses of pharyngeal samples of atmosphere taken at the height of expiration, and just following such an awakening, have shown a cyclopropane concentration of less than 1 per cent, gradually decreasing to traces during the following one to three hours. Although we prefer a gradual decrease in concentration during the last minutes of operation, elimination may be hastened following the removal of the mask by the display of sufficient carbon dioxide to maintain a brief hyperpnea.

#### CLINICAL LABORATORY STUDIES

Certain cases were studied to determine the changes in blood chemistry brought about by cyclopropane anesthesia. Although many more cases were observed than are used to compile the graph (fig. 2), we believe that the twenty-one cases there represented were the only ones in which the effects were produced solely by anesthesia and operation. No cases were omitted because of the seriousness or length of the operation. However, since oxygen want is known to cause changes in blood chemistry, cases that had shown severe respiratory obstruction during anesthesia have been omitted as well as others in which oxygen concentrations had been low because of technical error. Some cases were omitted because of the necessity having arisen during operation for intravenous medication. In the graph are shown average determinations for carbon dioxide combining power, sugar and nonprotein nitrogen, before, at the end of and four hours after anesthesia. The maximum and minimum readings in each item are not shown because they are approximately similar to the averages. In one exception a patient showed a rise of blood sugar content to 167 mg. per hundred cubic centimeters of blood without demonstrable cause other than the anesthetic. No patients with diabetes were studied. Four cases were studied for blood phosphorus changes, showing a marked increase and a quick return to normal. When these figures for phosphorus are

<sup>13</sup> It should be noted however that the pulse rate is not usually increased by cyclopropane and that the rate in a normal individual with moderate premedication and anesthetized with this agent by the carbon dioxide absorption technic is between 60 and 70 per minute.

<sup>14</sup> Seevers, M. H., De Fazio, S. F. and Evans, S. M. A Comparative Study of Cyclopropane and Ethylene with Reference to the Rate of Body Saturation and Desaturation to be published.

Erythrocyte counts have been made before, during and after cyclopropane anesthesia. Little change in the number of red cells was noted. As with ether and other inhalation agents,<sup>16</sup> a marked leukocytosis occurs, the maximum change being found from the third to the sixth hour after operation. In the average case this increase is from two to three times the preoperative count. Twenty-four hours postoperatively the white blood count has returned to one-half the maximum, and a normal count is usually reached on the third or fourth postoperative day. There is always a distinct increase in polymorphonuclear cells in the differential count, with a slower return to normal than that occurring with the total number of leukocytes.

## ELECTROCARDIOGRAPHY

Five clinical cases have been studied satisfactorily during cyclopropane anesthesia. Celiotomy of more than one hour duration was the operative procedure in each case. Electrocardiographic tracings were secured before anesthesia, during induction and every five to twenty minutes throughout the operation. Anesthesia was carried to plane 3 in three of the cases, and to stage IV in the other two. Four of the patients showed no electrocardiographic changes from normal other than a moderate slowing of the heart rate. In a single case during a two hour pelvic operation, significant changes were noted. During induction of anesthesia there was evidence of transient heart block in lead II. The next tracings fifteen minutes later were normal. After one and one-half hours operating, and with stage IV anesthesia, the tracing showed an inverted diphasic p wave and a shortened p-r interval. Ventricular extrasystoles

were noted. From observing these five cases, one would be led to the impression that electrocardiographic changes during cyclopropane anesthesia were certainly no more evident than changes during a corresponding degree of narcosis with any commonly used agent. A comparative clinical study of cyclopropane and other agents is in progress.

Since the clinical study is incomplete at this time, we take the liberty of commenting from a publication by Seevers, Meek, Roenstine and Stiles.<sup>3</sup> They observed electrocardiographic changes in unmorphinized dogs anesthetized with cyclopropane. Three dogs carried to complete respiratory arrest showed no changes during and following varying periods without artificial respiration. One dog spontaneously resumed normal respiration at the end of six minutes and the other two after shorter intervals. Experimental arrangements were then made to maintain artificial respiration in intubated dogs over long periods, gradually increasing the concentration of cyclopropane in as nearly as possible, a pure

Fig 2—Average determinations of carbon dioxide combining power, sugar, nonprotein nitrogen and phosphorus in the blood taken from patients 1 before, 2 at the end of and 3 four hours after operation under cyclopropane anesthesia.

oxygen vehicle. The dogs were allowed to reach either extreme respiratory depression or arrest and then respiration was continued by rhythmic compression of the breathing bag. Gas samples were taken in fourteen cases at the first appearance of electrocardiographic change (arrhythmia). The lowest concentration of cyclopropane was 26.6 per cent and the highest 72 per cent, with an average of 46.8 per cent. All fourteen dogs recovered normal electrocardiographic records in very short periods (from thirty seconds to two minutes) following artificial respiration with pure oxygen. Two other dogs died with ventricular fibrillation, occurring after short runs of ventricular extrasystoles and tachycardia. Gas analysis of the sample in one showed cyclopropane 71.4 per cent, and oxygen 17.7 per cent, in the other cyclopropane 52.0 per cent and oxygen 33.9 per cent. Artificial respiration did not effect recovery. A morphinized dog showed ventricular extrasystoles and ventricular rhythm on concentrations of cyclopropane under 30 per cent. After a 2 mg dose of atropine sulphate, arrhythmia ceased. Artificial respiration was maintained thereafter while the concentration

in Noninfectious Surgical Conditions Ann Surg 67 129 (Feb) 1918

was continuously raised until 72 per cent was reached without return of the arrhythmia

Slowing of the pulse rate seen preceding arrhythmia might indicate a vagal effect. The type of early arrhythmia is usually nodal rhythm or ventricular extrasystole. There may be a partial or complete auriculoventricular heart block. Later effects consist in ventricular tachycardia and auricular and ventricular fibrillation.

#### STATISTICAL ANALYSIS OF CLINICAL CASES

Advantage has been taken of the routine records kept by the anesthesia department of the Wisconsin General Hospital consisting of, first, preoperative observations taken from the clinical record and supplemented by the anesthetist's preoperative visit, second, the condition of the patient recorded by the anesthetist from minute to minute during anesthesia and operation as shown by blood pressure, pulse, degree of narcosis and other data, and, third, a postoperative record completed from a combination of the result of a personal visit by the

anesthetist because this agent is so lacking in potency without oxygen want as to afford little basis for comparison. When a very light degree of narcosis is desired, we prefer nitrous oxide and will continue to use it for the very reason that deep narcosis is impossible. The same group of surgeons working in the same hospital with the same anesthesia personnel, during the same period of time and with similar patients as to risk and type of operation, should make the comparisons fair even though the total number of cases is not great. The cyclopropane cases were selected at random from the total series administered, including those done early before experience had determined the most satisfactory technic or taught the character of the agent.

#### EXTRA-ABDOMINAL GROUP

Although cyclopropane has been used with satisfaction for thoracic surgery, eye surgery, obstetrics, operations on the mammary gland and the thyroid gland, genito-urinary surgery and tonsillectomies, all these are excluded because one or the other of the agents compared is thought to be contraindicated for such operations. The series includes central nervous system, bone and joint, plastic, vaginal and rectal surgery, hernias and miscellaneous general surgery outside the abdominal cavity.

The preoperative condition of these patients was similar in the three groups. For example, coughing was present in 3 per cent of the ether, 4.5 per cent of the cyclopropane and 4.1 per cent of the ethylene cases. Chronic pharyngitis was diagnosed in more than 11 per cent of each group, and oral sepsis in from 20 to 26 per cent of all the cases. The circulatory abnormalities were not less frequent than is expected in a hospital treating charity patients almost exclusively. Myocardial degeneration was a factor in 3.4 per cent of the ether, 7.8 per cent of the cyclopropane and 2.8 per cent of the ethylene cases. Arteriosclerosis averaged about 10 per cent, and patients with a functional capacity of grade II-A or less constituted 1.8 per cent of the ether, 4.1 per cent of the cyclopropane and 2.3 per cent of the ethylene cases. A nonprotein nitrogen of more than 40 was present preoperatively in 1.9 per cent of the ether, 3.5 per cent of the cyclopropane and 4 per cent of the ethylene cases. Fifty-seven of the 1,800 patients, equally divided for the agent, had brain or spinal cord lesions. More than 5 per cent of each group complained of headache, and a malignant condition was noted in 4.67 per cent of the ether, 5.3 per cent of the cyclopropane and 4.5 per cent of the ethylene cases.

During operation the complications in this series were practically nil except for surgical shock. In 2 per cent of the ether, 1.8 per cent of the cyclopropane and 2.2 per cent of the ethylene cases, third degree circulatory depression developed during operation. Pulse rate and systolic and diastolic blood pressures have been recorded throughout all anesthesia. No distinct differences were noted, and changes appear to have depended more on bleeding, operative manipulation and anesthetic technic than on the agent used. The respiratory rate was slower in the cases in which cyclopropane was administered.

Postoperative complications graphically represented in figure 3 include all the complications recorded in the nurse's notes and staff progress notes, as well as those gleaned from a personal visit to the patient. Many patients had more than one complication, and in a large number the postoperative complication was present preoperatively. Not every minor complication is included,

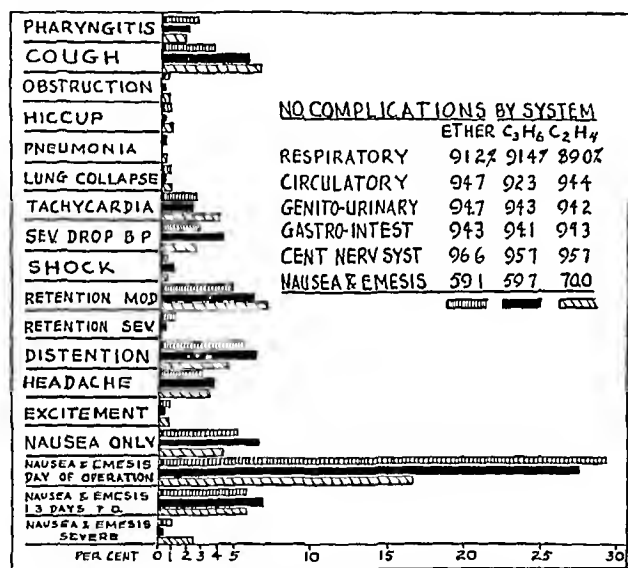

Fig. 3.—Postoperative morbidity following 600 cases each of anesthesia with ether, cyclopropane and ethylene for extra abdominal surgery. The table shows by systems the percentage showing no complications. The graph represents the percentage incidence of each complication.

anesthetist from the third to the fifth postoperative day with inspection of the bedside record at this time, and checked by a review of the clinical chart at the time of discharge or death. Finally, the completed anesthesia record is transferred to a punch card, which is then available for machine sorting in the compilation of statistical data.<sup>17</sup> Thus the comparative information concerning ether, cyclopropane and ethylene recorded in the accompanying graphs is taken from the routine records of the hospital and does not involve special observations made because of this study.

In the extra-abdominal group, a series of 600 operations with ether anesthesia are compared with a similar number with cyclopropane and ethylene. Ether having been our previous choice for abdominal operations, 400 such operations done with this agent are compared with 400 similar operations under cyclopropane. This affords a comparison of cyclopropane with the older agents ether and ethylene. Nitrous oxide has not been

<sup>17</sup> Rovenstine, E. A. A Method of Combining Anesthetic and Surgical Records for Statistical Purposes. *Anesth. & Analg.* 13: 122 (May-June) 1934.

and instances of a single occurrence are not recorded. For example, phlebitis was noted once in the 1,800 anesthetics.

#### ABDOMINAL GROUP

In the abdominal group the type of operation was about equally divided between the upper and lower parts of the abdomen for the 400 ether and 400 cyclopropane cases. Hemorrhaphy was included in the extra-abdominal group.

Preoperative complications in this group were more extensive. The respiratory and circulatory systems presented about the same percentage of preoperative

or shock occurred distinctly more frequently after cyclopropane than following the other agents. In this connection it should be noted that myocardial degeneration had been recorded preoperatively in more than twice as many of the extra-abdominal cases in which cyclopropane was given as of those in which the other two agents were administered.

#### DEATHS

The deaths occurring in the 2,600 cases statistically studied are shown in the table. The time of death as well as the cause is recorded.

Tissues taken at autopsy from fifteen of the forty patients dying in the hospital who had received cyclopropane have been carefully studied by Dr. C. H. Bunting for evidence of tissue damage that might have been brought about by this agent. Briefly his comment is as follows:

The attention of the laboratory was directed toward possible harmful effects of cyclopropane as an anesthetic by the occurrence in a patient after prolonged anesthesia of lesions comparable to those seen in dogs after excessive anesthesia with the same drug. These consisted of hyaline degeneration and necrosis of heart muscle fibers and hyaline necrosis of cells of the convoluted tubules of the kidney.

As a result, the organs in fifteen fatal cases have been scanned rather carefully for indications of injury, especially to the heart, kidney and liver. It has been difficult to evaluate the lesions found as the patients had been on the whole

	Extra-Abdominal Cases			Abdominal Cases	
	Ether	Cyclopropane	Ethylene	Ether	Cyclopropane
Number of cases	600	600	600	400	400
Total deaths	23	13	22	27	27
Mortality, per cent	3.8	2.16	3.66	6.75	6.75
Time of death					
Day of operation	1	1	1	2	1
13 days after operation	4	4	1	5	3
47 days after operation	1	2		8	6

Other circulatory diseases	3	0	2	4	4
Toxemia	9	1	9	7	10
Carcinoma	3	4	4	5	4
Shock	0	0	0	1	1
Others	3	2	2	1	2

complications. There were fewer central nervous system abnormalities. Intestinal obstruction was present in 52 per cent of the ether and 75 per cent of the cyclopropane cases. Nausea and emesis before operation was present in 15.8 per cent of the former and 17 per cent of the latter. A malignant condition was diagnosed in approximately 12.5 per cent of each.

During operation, complications were rare. Emesis occurred during operation in 1 per cent of the ether and 0.5 per cent of the cyclopropane cases. Shock developed in 17 per cent of the ether anesthetics and in 2 per cent of the cyclopropane anesthetics. As in the extra-abdominal group, no significant differences in pulse rate or blood pressure were noted. Respiratory excursion was definitely less in patients receiving cyclopropane, often adding considerably to the convenience of the surgeon.

Postoperative complications, graphically recorded in figure 4, were determined in the same manner as described for the extra-abdominal group. All complications were included, even though they were present before operation. Many patients had several complications.

It will be seen from a careful perusal of figures 3 and 4 that nausea and emesis following anesthesia for operations outside the abdominal cavity was similar to that following ether and distinctly more frequent than following ethylene, although distinctly less severe. Following abdominal operations, nausea and emesis was less frequent and less severe than after ether. Pneumonia did not occur after cyclopropane in the extra-abdominal group, and massive collapse was less frequent. The incidence of pneumonia following abdominal operations under cyclopropane was less than one-third that after ether. Lung collapse was also distinctly less frequent. Tachycardia, a severe drop in blood pressure

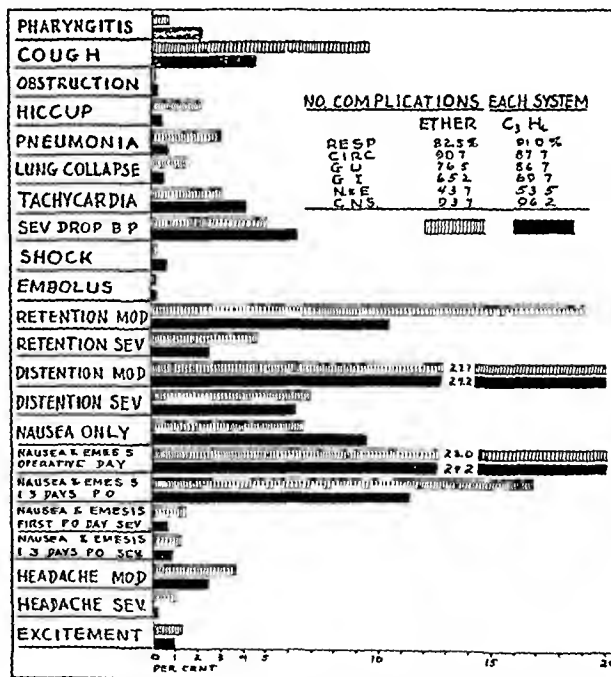

Fig. 4—Postoperative morbidity following 400 cases each of anesthesia with ether and cyclopropane for abdominal surgery. The table shows by systems the percentage showing no complications. The graph represents the percentage incidence of each complication.

extremely handicapped not only by chronic lesions but by acute terminal infections. Therefore, any notation as to lesions must be accepted as subject to correction on more extended study.

The general observations are as follows:

**Heart**—A definite tendency toward hyaline degeneration and necrosis of heart muscle fibers has been noted. This may involve complete fibers or may be limited to a marked hyaline swelling of the intercalated disks and evidence of injury to the adjacent part of the fiber. In two cases with a survival of two weeks or more after operation there was found a fairly widely disseminated hyaline degeneration of the peripheral sarcolemma

of the muscle fibers. The unusual character of the lesion suggested the possibility that it was due to cyclopropane, yet the late occurrence of it might discredit that suggestion.

*Liver*—No necrosis of liver cells that could be attributed to the anesthetic was found in any case. The lesions found were fatty degeneration and hydropic degeneration, suggesting the reduction in oxidation processes common to all the usual anesthetics.

*Kidney*—The lesions of the kidney were in general of a degenerative nature, nonspecific in character, including parenchymatous, fatty and hydropic changes. Colloid degeneration of the ascending limbs of Henle was present in two cases. In several cases, more serious damage was indicated by the presence of hyaline necrotic cells found in the tubular lumen.

Several dogs have been anesthetized for periods as long as nine and sixteen hours and others for shorter periods frequently repeated. Such dogs have later been killed and their tissues are being studied. These are the animals referred to by Dr. Bunting. The patient to whom he refers in the same paragraph had been subjected to hysterectomy the day before death. The operation was technically difficult and hemostasis most unsatisfactory. Third degree circulatory depression (shock) was present during the last seventy-five minutes of operation in spite of treatment.

#### COMMENT

Induction with cyclopropane has appeared to be quite as pleasant as is that with nitrous oxide, though less rapid with the technic which we have used. Sensations of "ringing in the ears," "fulness" in the head and other unpleasant experiences seem less frequent than with other agents. This we have attributed to the complete avoidance of oxygen want from the beginning of inhalation. The ability to induce deep anesthesia without respiratory stimulation, irritation or the possible necessity of producing oxygen want gives the anesthetist a feeling of safety and assurance not experienced with any other agent.

Recovery has seemed to be more frequently accompanied by nausea than following nitrous oxide and ethylene. A curious observation has been made that severe nausea or nausea and emesis have more often followed minor administrations to expected ambulatory patients than to patients hospitalized for major surgery. We would therefore consider nitrous oxide the agent of choice for minor cases of short duration when suitable. Rather than risk oxygen want with nitrous oxide, however, we prefer to supplement nitrous oxide lightly with cyclopropane, returning to nitrous oxide at the earliest possible moment. For major surgery we think that the incidence of nausea and emesis is less pronounced than with the other agents in common use. The speed with which recovery takes place does not differ from the awakening following a nitrous oxide or ethylene anesthesia, provided the patient is in first plane anesthesia when the mask is removed.

As a preliminary to ether anesthesia, cyclopropane has given satisfaction. The induction is pleasant and the tolerance to ether vapor in the presence of a high oxygen content of the inspired gas makes for a smoother and quicker ether induction.

It is agreed by all members of the anesthesia staff that the induction of endotracheal anesthesia is easier with cyclopropane than with ether or ethylene. Although there may be slight stimulation of mucus following laryngoscopy and intubation, in patients receiving no premedication, we have nevertheless done many endotracheal anesthetics for brain surgery when no pre-

liminary opium derivative, barbiturate or atropine-like drug had been given. Endotracheal cyclopropane, with large tubes for "to-and-fro" breathing,<sup>5</sup> is very satisfactory for brain, dental and many abdominal cases as well as for plastic work about the head. Except for central nerve surgery, morphine and scopolamine have been used as premedication. Many of these cases are finished with nitrous oxide after intubation with cyclopropane.

In performing thoracoplasty, rib resection for empyema and other operations within or outside the chest the extremely quiet respiration, ample oxygen supply and quick recovery of the cough reflex have appeared to the anesthetist to offer ideal conditions for this work. Ease of intubation when needed is an added advantage.

In the lower part of the abdomen, including all gynecologic procedures through an abdominal incision, satisfaction has been complete for surgeon and anesthetist. Relaxation is ample. For upper abdominal work, cholecystectomy and stomach resections, for instance, noticeable defect in the relaxation has been evident in many cases. In the strong muscular type, the rectus muscles are relaxed and breathing is quiet without "forcing" the anesthesia. However, during closure of the wound, the surgeon finds the peritoneal margins retracted under the recti, sometimes causing difficulty in closure. Having had similar experiences with ether in certain cases, we have used similar remedies.

For many years, nitrous oxide has proved satisfactory for intermittent relief from pain during parturition. For a majority of patients in labor, potency and muscular relaxation are to be avoided. Only relief from pain is desired. We still prefer nitrous oxide in the early stages of labor in all cases and throughout in most. A very small amount of cyclopropane added to nitrous oxide during second stage pains has been found useful in adding potency for the occasional woman the severity of whose pains is too great to be completely relieved by nitrous oxide. In forceps delivery, version and extraction, and cesarean section cyclopropane has proved immediately satisfactory in the few cases in which it has been used. A study of a large series of cases to determine the incidence of postpartum hemorrhage and other complications should be made. Continuous administration of cyclopropane in very light dosage by the carbon dioxide absorption technic in three obstetric cases has resulted in partial relief from pain with retained consciousness. The possibility of obtunding the sensation of pain with cyclopropane, without the production of unconsciousness, warrants further study.

#### APPLICABILITY OF CYCLOPROPANE

At the end of a year's study of the possible usefulness of this agent for clinical anesthesia at the Wisconsin General Hospital, we find it replacing ethylene to the satisfaction of anesthetists, surgeons and patients. We choose it in preference to ether in well over 75 per cent of the work formerly done with that agent. In the cases in which ether is still used, there seems to be an increasing tendency to choose cyclopropane in preference to nitrous oxide as a means of inducing ether anesthesia.

Our own analysis of the comparative graphs of postoperative complications leads us to believe that we may expect slightly better results by the use of cyclopropane in patients handicapped by respiratory and circulatory abnormalities. We must, however, emphasize our firm conviction that the careful individual attention of a

skilful anesthetist, well versed in the physiologic principles on which efficient respiration and circulation depend, is much more important in preventing damage to handicapped patients than is the agent used to produce relief from pain

## Clinical Notes, Suggestions and New Instruments

### ZIPPER BANDAGES

GERALD H PRATT MD PHILADELPHIA

Abdominal incisions require adequate support for a long period after operation and by elimination it has been established that this support is best supplied by the application of adhesive tape strips, long enough to include the back muscles. Inadequate support to the incision in the postoperative period probably contributes as much as any other factor to wound rupture. This tight adhesive application is difficult and often painful to remove. Especially is this true in hairy males or in lower abdominal operations in which the incision encroaches on the pubis. Thorough shaving preparation does not eliminate the trouble, as the hair grows into the adhesive tape before the time of the first dressing. When the skin is burned by the iodine or other sterilizing solution, or when there is an irritating drainage, the changing of the adhesive at dressing times becomes a serious ordeal.

As most surgical routines require the dressing to be changed about the seventh and twelfth days for the removal of the superficial and retention sutures, there must be at least three changes in the adhesive tape. When there is drainage it is often necessary to change the dressings several times a day. To avoid this annoyance many ingenious devices have been described. The Montgomery straps seemed to solve the problem for a time, but it was found that the simple strings were not sufficient to hold the abdomen and many ruptures of the wound followed their routine use. In one institution there were three such "blow-outs" in a month, emphasizing for all time the inadequacy of this type of dressing, at least in the early postoperative days. Particularly in drainage problems with an already weakened wound, is this prone to occur.

Fig 1—Zipper bandage applied

At present most surgeons resort to cutting the adhesive tape down the center and stripping it free from the underlying dressing, thus having an access to the wound. It is then closed with either new adhesive tape or laced through cut out openings. This is only partially satisfactory, as it is difficult to cut and requires the surgeon to contaminate his hands in the soiled dressing. This procedure is not without its discomfort to the patient.

In the Babcock surgical service at Temple University Hospital we have been using that ingenious device which seems to have found its way into nearly everything used today, the zipper. It has solved our problem very nicely and we suggest its adoption by others of the profession, both in abdominal and in extremity work.

From the Babcock Senior Surgical Service Temple University

We obtained the zippers at the five and ten cent store in various lengths. These zippers are sold with a small border of cloth tape around them for attachment. This lends itself to incorporation into the adhesive tape. Sufficient adhesive strips are cut and overlapped, and the end next to the zipper is folded over so that there is a three inch facing on the adhesive side. A simple rubber punch is used to make multiple perforations at distances from half an inch to an inch in both the cloth tape around the zipper and in the faced adhesive strips. We use a punch that places a metal eyelet on the zipper tape to prevent fraying after much use. A piece of string or tape is then laced through these openings in the zipper cloth and the adhesive tape, thus joining the adhesive tape securely to the zipper. The finished dressing is then applied, one adhesive strip on each side at a time and the tape strings are tied at the top and bottom in a bow knot. The facing of the adhesive tape pre-

Fig 2—Zipper opened by nurse for dressing change. The faced adhesive tape assures an adequate opening to give free access to the wound.

vents the dressings from sticking to the adhesive tape and greatly facilitates their removal.

The zipper may be removed after use by merely pulling out the lacing on each side. It is washable and sterilizable, does not rust, and may be used any number of times. After the first experience it is easily prepared by the nurse and kept in readiness on the dressing carriages.

The patients react very favorably to the idea. This is true particularly when previous dressings or operations have made the patient apprehensive about the removal of the dressings. The draining wound may be changed freely by the attendant physician or nurse without the mechanical difficulty of opening a dressing without contamination. We find that many more dressings requiring attention every few hours can be assigned to the nurse, thus assuring regularity. The device is applicable when irrigations such as with surgical solution of chlorinated soda are being carried out, and is of great value in such wounds as osteomyelitis, fecal fistula and biliary fistula. When drainage is excessive, the use of gutta percha or cellophane is of assistance in preventing soiling of the outside coverings.

### SARCOMA OF THE PROSTATE

OSWALD SWINNEY LOWSLEY MD, AND FRANCIS NELSON KIMBALL MD  
NEW YORK

Sarcoma of the prostate is such a rare finding that it is considered proper to report our case in considerable detail. A diagnosis is often difficult to make, and this case is unusual in that it occurred to a man late in life. The literature shows, however, that our case is not unique in that regard.

#### REPORT OF CASE

S E B, a man, aged 64, admitted to the Urological Department of the New York Hospital (James Buchanan Brady Foundation), May 19, 1930, complained of frequency and dribbling. The frequency began about three years before admission and greatly increased in severity until the patient voided on the average of every hour, day and night. The micturition was always painful. Dribbling began one year before. At first it

From the Department of Urology (James Buchanan Brady Foundation) of the New York Hospital

# SARCOMA OF PROSTATE—LOWSLEY AND KIMBALL

JOUR. A. M. A.  
SEPT. 29, 1934

occurred at the end of micturition. On admission it was constant. Cystoscopy had been performed about one month before and he was told that he had a moderate intrusion of the prostate. Immediately following this procedure there was marked bleeding from the urethra, but this gradually subsided.

His family and past personal histories were unimportant, except that he had a gonorrheal infection at the age of 24. Recovery was uncomplicated. He had a syphilitic infection at the age of 29 for which he received vigorous antisyphilitic treatment. The blood Wassermann reaction had been negative during the past thirty years. Physical examination showed that the hearing was slightly impaired. The heart was slightly enlarged, and the blood pressure was 170 systolic, 88 diastolic. On rectal examination the prostate was found to be about two and one-half times the normal size, flattened in type and leathery in consistency. It was our impression that the patient had an

was greatly disturbed because of pain in the right side and flank and an elevation of temperature. However, for one week his temperature had been normal. During his absence from the hospital he returned at frequent intervals for phenolsulphonphthalein tests and blood chemistry examinations, but the kidney function was so poor that it was impossible to do the second stage of the operation. On readmission to the hospital another cystoscopy was attempted after the suprapubic tube had been removed from the wound and the wound tightly closed by digital pressure. The instrument passed without difficulty, although it seemed to assume a peculiar angle as it entered the bladder. There was a tremendous intrusion into the bladder of the median portion of the prostate. The ureteral orifices could not be seen. The prostate appeared to be about the size of a hen's egg. The prostate appeared urography was done. Three hours after injection the right kidney pelvis was seen to be about five times its normal size and the ureter was tremendously enlarged and distorted. The left kidney shadow pictures were not visualized in any of the shadows in the right upper quadrant, which were thought to be gallstones.

The patient gradually grew worse, marked emphysema, bronchitis, and marked embarrassment to the circulation with enlargement of the liver developed, and death occurred December 17, 1933. The probable cause of death was uremia.

An autopsy was obtained and the pertinent urologic observations were as follows:

**Kidneys**—Gross Examination. There were some significant changes. The perirenal fat tissue was considerable in amount and could be readily peeled from the kidneys, their capsules being removed with the surrounding fat. The right kidney felt small and soft. The left kidney was dilated to almost the size of the kidney itself and contained cloudy mucinous material. When the pelvis was empty this kidney weighed 175 Gm. The medullary portions seemed to be relatively more thinned out by the greatly dilated renal pelvis than the cortex. The kidney substance was 2.5 cm thick around the pelvis. The left kidney seemed even more injured by the hydronephrosis than did the right. After the pelvic fluid had been drained the kidney weighed 135 Gm. The kidney cortex was 1 cm in thickness.

**Microscopic Examination.** The left kidney showed extensive interstitial fibrosis. There was a moderate amount of lymphocytic infiltration, especially in localized areas. The tubules were quite sclerotic. The right showed a similar picture with rather less fibrosis but much more marked cellular infiltration. Fairly numerous polymorphonuclears were found in addition to the very large numbers of round cells.

**Ureters**—These were both greatly dilated throughout. They were fairly uniformly 1.5 cm in diameter throughout and contained thick white mucinous urine. There was a slightly smaller diameter where the right ureter crossed the pelvic brim. The dilated ureters extended to the bladder wall.

**Bladder**—Gross Examination. The bladder communicated well preserved with the suprapubic sinus. The bladder contained almost no urine. It was closed down so as practically to surround the prostate without any remaining lumen. The prostate was enormous, being 8 cm in length, 5.5 cm in width and 4.7 cm in thickness (i. e., about the size of a tennis ball). The ureters could not be recognized from inside the bladder but when probed into from the outside they were found to empty into the bladder on the most prominent portion of the anterior surface of the prostate. Their openings were very oblique and a probe within them could be seen through the bladder mucosa almost 1 cm above the point of opening. There were a few small diverticula superior to the

Wm P. Diduch 1931

Sarcoma of the prostate showing the bladder opened in the anterior midline exposing the tremendous sarcomatous growth which almost completely filled the bladder. The right and left ureteral orifices can be seen on the surface of the tumor mass. Ureteral catheters have been introduced to demonstrate these openings. Both ureters, although showing presence of back pressure were patent. The right kidney is shown in section demonstrating a marked degree of hydronephrosis. The left kidney was also hydro-nephrotic and the external form showed cyst formations on its surface. The high insertion of the ureters is evident and below on each side is seen the lower portion of the sarcomatous growth. The bladder wall showed marked hypertrophy of its musculature. There was no evidence of a trigon present.

adenomatous hypertrophy of the prostate. Further physical examination prior to operation did not reveal anything unusual and the interior of the bladder showed a moderate intrusion of the prostate. Following the operation the patient made an uneventful recovery, but the kidney function failed to show any appreciable improvement. June 20 the patient was discharged from the hospital, as removal of the prostate was deferred until a more favorable period.

October 13 the patient reentered the hospital and told us that his condition had improved rapidly after he had left the hospital, except that his appetite was very poor and his sleep

prostate. On section, the prostate seemed to consist almost entirely of fibromuscular tissue. The enlargement seemed to be most prominent in the so called middle lobe, but the lateral lobes were almost as much enlarged. Posteriorly the seminal vesicles and ampulla of the vasa deferentia were displaced somewhat laterally by nodular projections from the prostate. The ureters were displaced upward. The bulk of the growth grew into the bladder, suggesting that the process originated in the middle lobe.

**Microscopic Examination.** Several sections were studied. In all of them the picture was that of sarcoma, apparently of smooth muscle origin, as shown by van Gieson's stain (leiomyosarcoma). No glandular element was recognized in any section. The spindle-shaped cells varied greatly in size, and very large nuclei were found in many of the cells. There was very little cellular infiltration. Although we are listing this case as sarcoma, we do so largely on histologic grounds.

**Genitalia.**—The seminal vesicles were both firm and large. The testes were soft and yellowish. Microscopically the testes showed some atrophy. There was no evidence of invasion in the seminal vesicles or in the testes.

#### SUMMARY

Uremia followed a ureteral obstruction by an enormously enlarged and histologically sarcomatous prostate.

The clinical diagnosis was adenomatous hypertrophy of the prostate, right hydronephrosis and uremia.

The anatomic diagnosis was leiomyosarcoma of the prostate, bilateral hydro ureter, bilateral pyonephrosis, cholelithiasis, emphysema and bronchopneumonia.

## THE PRESENT STATUS OF RADIATION IN THE TREATMENT OF CANCER

CLINICAL LECTURE AT CLEVELAND SESSION

ARTHUR C. CHRISTIE, M.D.

WASHINGTON, D. C.

Substantial improvement has occurred in the past few years in the treatment of cancer. This has been due to several causes, among which are improvements in apparatus for roentgen therapy, advances in technic in the application of both the roentgen ray and radium, and a change in attitude which permits radiation treatment of patients favorable for cure. There are reasons to believe that further improvement will take place in all these respects, but the results already attained justify a reappraisal at the present time of the place of radiation therapy in cancer.

Since the cause of cancer remains undiscovered, its treatment is still empirical. This is true of radiation as of other methods. The rational basis for radiation therapy goes back to the early discovered fact that embryonal types of cells are more radiosensitive than adult forms. The sensitivity peculiar to each kind of cell appears to be related to the life cycle of the cell, that is, the shorter the life cycle the more sensitive to radiation and vice versa. Lymphocytes have the shortest life cycle and are therefore most sensitive to radiation, bone and nerve cells have the longest life cycle and are therefore most resistant. Experience has fully established this principle, but it is now well known that

other equally important factors enter into the problem of the curability of cancer by irradiation. Because of this it has been appropriately suggested that "radio-curability" is a better term than "radiosensitivity" for use when an attempt is made to estimate the probability of cure by radiation. Among other factors that are equally important with radiosensitivity of the cancer cells are the general condition of the patient and his reaction to radiation, the immediate tissue environment of the cancer (the cancer bed) and the relation of the growth to vital organs or important tissues that may suffer injury.

It is thoroughly established that the beneficial effects of radiation on malignant growths are due not only to the direct changes produced in the growth itself but equally to the reaction of the surrounding healthy tissues.

The explanation of the fact that some cancers show initial marked regression under irradiation but finally reach a point at which there is no further effect is probably due to several factors. One of these is the fact that the more radiosensitive cells are destroyed by the early treatment, while those that are radioresistant to the particular dose administered persist. Repetition of an equal dose will not destroy such cells any more than did the initial dose. If radiation is to accomplish additional good in such cases it must be given in a larger dose, and this is often inadmissible because of the injury that may result to the normal tissues. Great harm, with little probability of additional benefit, may be done by repeated irradiation without change of dosage. Another factor that may terminate the beneficial effects of radiation is the permanent change that occurs in the surrounding healthy tissues. They will sooner or later reach the point at which the capacity to react to irradiation is exhausted. The ideal now aimed at is to apply the total radiation dose in such a manner as to secure the optimum relation between destruction of neoplastic cells and the normal tissue reaction, the latter not being carried to such a point that prompt recovery is impossible.

Methods have been devised in the past few years which constitute an important advance in respect to proper and efficient dosage. Except in superficial cancers in which it is possible to destroy the growth by the caustic effect of radiation, the single massive dose method has been practically abandoned. Some type of fractional dosage is now in general use. The "saturation" method of Pfahler consists in administering a large initial dose and maintaining the radiation effect at a maximum by giving a small daily dose until the total dosage is attained. Theoretically the advantage of this method is that the maximum effect on the tumor cells is obtained at a time when the normal tissues are still able to react strongly. The Coutard fractional dose method of applying the roentgen ray consists in giving a very large total dose over a prolonged period (from eighteen to thirty-five days), an equal amount being given daily until the total dose has been reached. Essential factors in the method are relatively high voltage (at least 200 kilovolts) and heavy filtration (from 1 to 2 mm. of copper or its equivalent). Results have been obtained by this method, to which I will refer later, which are superior to any previously thought possible. Holfelder has used a method that aims to take advantage of the large initial dose of the "saturation" method and subsequently to build up the dosage by

Annual Session of the American Medical Association, Cleveland, June 11,  
1914.

## IRRADIATION OF CANCER—CHRISTIE

JOUR. A. M. A.  
SEPT. 29, 1934

the method of Coutard. The increased benefits from the fractionated dose method appear to arise from the improvement in the ratio between the destructive effect on the neoplasm and the reaction in the surrounding normal tissues.

Progress has taken place also in methods of radium therapy, especially in respect to interstitial radiation. The use of gold and platinum seeds was a great advance over glass seeds for the interstitial application of radon, the increased filtration lessens the danger of localized necrosis, so likely to occur when glass seeds are used. There has also been improvement in the use of radium element in needles by increasing the filtration to at least a millimeter of platinum and by using smaller needles to minimize trauma. One of the difficulties in the use of seeds and needles is that of securing a uniform distribution in the area to be irradiated. This was partly solved by the use of seeds or needles with a very small content, but better still by tubules or needles from 3 to 6 cm. in length with a very small amount of radon or radium element to the running centimeter. The use of such needles makes it possible to transfuse the tissues in the form of a grid and thus to secure fairly uniform dosage.

Improvements that have been made in roentgen apparatus in the years immediately past are of importance equal to those made in technic. Machines are now in common use delivering from 20 to 30 milliamperes of current at 200 kilovolts (recently the voltage has been increased to 350 kilovolts), and tubes are available to withstand such currents. In a few places in the country special apparatus has been installed to operate at 750 and even 1,000 kilovolts. There is not yet sufficient evidence to show that such voltages produce results that are an improvement over those obtained at from 200 to 350 kilovolts. There are indications, however, that the clinical results will be found somewhat better than those being secured at present. It seems quite certain that the results in cancer are due to the amount of radiant energy that can be delivered to the cancer without permanently injuring the normal structures and that the voltage per se is of no importance. There are indications now that further advance may be made in roentgen apparatus by securing a much greater energy output by the use of tremendously higher milliamperage rather than by an increase in voltage. Such machines would not require the large space of those of very high voltage and would make possible the same biologic results by enabling the operator to treat at a much greater distance from the patient, thus securing the proper relationship between surface and depth dosage. I have mentioned these advances to show that the possibilities of radiation in the treatment of cancer are not yet exhausted.

In an attempt to appraise the present position of radiation in malignant disease, the fact must be kept in mind that results up to the present moment have been obtained over a period of time during which the technic of treatment has been constantly changing. This has been due to new discoveries and inventions of apparatus and to a constantly widening experience. During most of this time the general attitude has been, and rightly so, that radiation was in an experimental stage. Except in the field of skin cancer, up to very recent times it was considered unjustifiable to treat by radiation any but the most advanced and hopeless cases and to use it

as an adjunct to whatever surgical methods were thought advisable. Because of results obtained in large numbers of primarily inoperable and seemingly hopeless conditions and in recurrences after operation, and because of improvement in results when used in addition to surgery, the attitude toward radiation has radically changed during the past three or four years. Some conditions that were formerly entirely in the surgical field have now been given over to radiation therapy, notably cancer of the uterine cervix and many types of skin cancer, in others wide dissection and removal of regional glands has been replaced by radiation treatment of the primary growth, and perhaps interstitial irradiation of regional nodes, and perhaps removal of glands that persist after such treatment, that is, radiation has become the primary method instead of being used as an adjunct to surgery. In other regions of the body the question of operability is now being scanned with much greater care than formerly, since it has become known that in many cases formerly considered operable, but in which the percentage of cure is very low, much better results may be obtained by radiation alone or by radiation followed by limited surgery.

## PLACE OF RADIATION IN VARIOUS TYPES OF CANCER

Under such circumstances of rapidly improving apparatus and technic and with an almost revolutionary change in the type of cases coming under treatment, statistical evaluation of past results has no absolute value. It serves only to indicate trends and possibilities and to point out probable lines of progress. Great care always must be exercised in interpreting the statistics that are offered in cancer under any method of treatment. General statistics of five year cures of cancer of any particular region of the body are peculiarly valueless unless they contain specific information with regard to numerous factors. For instance, five year cures in cancer of the breast mean very little unless one knows the percentage of cures in each of several age periods and has detailed information with regard to the histologic type and clinical aspects of the disease and the presence or absence of glandular involvement.

With the foregoing preliminary considerations in mind I shall proceed to an appraisal of the place of radiation in various types of cancer. It is obviously impossible to discuss the subject exhaustively in a paper such as this, but I shall try to illustrate all the principles involved by considering somewhat in detail several different regions.

Because they are accessible and usually can be irradiated without great danger to normal structures, cancers of the skin have been treated by radiation methods almost from the time of the discovery of the roentgen ray. The great majority of skin cancers are either basal cell or squamous cell epitheliomas. The basal cell type when it is still small and does not involve cartilage or any other important structures is readily curable by any one of several different methods. It is a local disease without tendency to involve the regional lymphatics or to metastasize to distant parts and can be cured by complete local destruction by the roentgen-ray, radium or electrothermic methods or excision. Which method

used is not so important as thoroughness in destroying the local lesion. When basal cell cancers become very large or involve bone or cartilage they are a more difficult problem, and radiation occupies the most important place in their treatment. A considerable percentage of such lesions can be cured by modern methods of radiation, sometimes assisted by electrothermic destruction of fungating masses. The fractionated method of Coutard constitutes an epochal advance in dealing with lesions involving cartilage. Formerly, destructive doses of roentgen rays or radium about the cartilages of the ear, eyelids, nose or larynx frequently produced a painful perichondritis or necrosis, a condition more difficult to cure than the original cancer. By applying highly filtered roentgen rays daily over a long period, the lesion may be completely destroyed and the normal tissues saved from irreparable damage.

Squamous cell epithelioma is much more important in its menace to life than the basal cell type. It early invades the lymphatics and involves the regional lymph nodes and may metastasize to distant parts of the body. Because of their invasive tendency, it is important to treat and destroy them while they are still localized. When they come under observation, however, there is no means of determining to what distance along the lymphatic drainage system cancer cells have already found their way. Excision of the local lesion is therefore a dangerous procedure, since it must be done blindly, it is only by chance that the limit of excision will extend beyond the invaded area. Whatever method is chosen to destroy the local lesion, the primary treatment should be thorough roentgen irradiation of the entire lymphatic drainage area by the fractional method.

There is a difference of opinion about the advisability of biopsy to settle the diagnosis. Nothing has been more thoroughly established than the fact that trauma by cutting through or otherwise injuring cancer-bearing tissue, greatly increases the danger of dissemination of the cancer cells, both locally and to distant parts. There are important advantages in definitely establishing a diagnosis of malignancy and in knowing the type of histologic structure present, but the added danger of dissemination must be weighed when biopsy is contemplated. Some believe that the importance of the knowledge to be gained outweighs the danger, while others feel that biopsy should be postponed until about two weeks after roentgen irradiation in order to lessen the liability of spread.

Not only is it of prime importance to irradiate the regional lymphatic drainage area as the first step in treatment, but the method of dealing with the primary lesion is also of great importance. I believe that the method of choice in treating the local lesion is a destructive dose of roentgen rays or surface application of radium, administered at one sitting about the time when the series of treatments is begun over the regional lymphatics. Six weeks after such treatment, enlarged lymph nodes may have disappeared and the original lesion may be healed. If there is any residuum of the primary lesion it can then be destroyed by electrocoagulation or by implanting interstitially gold or platinum radon seeds or small needles of radium element. Any lymph nodes that remain palpable may be laid bare by careful incision and radon seeds or radium needles implanted.

The method described is applicable to epidermoid cancer of the squamous or transitional cell type, any-

where on the skin. In cancer of the lip it is a much more rational method than excision followed by irradiation. If excision is to be done at all, it should always be preceded by irradiation. If cancer recurs after simple excision, it is a traumatized cancer with much greater potentialities for harm than the original lesion and with much less chance of cure by radiation therapy.

The reason that roentgen irradiation in a destructive dose or surface application of radium is preferred for the primary lesion rather than interstitial irradiation is that implantation, even of small seeds, produces considerable trauma and increases the drainage from the cancer area. Previous roentgen irradiation can do no harm and may introduce a vital element of safety.

One important consideration in radiotherapy not only of skin cancer but of cancer in any other part of the body is that practically all that is to be done should be accomplished in the first series of treatments. The possibilities of reaction in the surrounding tissues may never again be so favorable after those tissues have suffered the changes produced by irradiation. For this reason it is necessary to plan the initial treatment with the greatest attention to detail and to administer it with meticulous care. It must be realized more fully that radiation therapy of cancer to be efficient is a radical procedure and must not be entered into lightly and casually. It is just as radical a method as surgery and may require even more skill, judgment and experience for its proper use. It is important that both the medical profession and the public understand this.

I have already referred to the long known fact that the degree of sensitivity of cancer to radiation depends on its histologic structure. The cellular, undifferentiated tumors are the most radiosensitive and at the same time the most malignant. The squamous cell epitheliomas, which have just been considered, are moderately radioresistant, but there is a wide range of susceptibility to radiation even within that class of tumors. The more nearly the morphologic changes approach those of normal epithelial tissue, the less malignant they are and the more radioresistant. In more rapidly growing tumors there is less tendency to formation of pearls and connective tissue stroma and more tendency to formation of masses of undifferentiated cells. A single small squamous cell tumor may exhibit several grades of malignancy, parts of it may be highly differentiated and hence radioresistant, while other parts may be composed of masses of cells with no tendency to differentiation and with marked hyperchromatism and variation in cell size, and hence radiosensitive. These facts are of importance not only in the prognosis but also in the treatment.

There are several regions besides the skin in which epidermoid cancer is a frequently occurring lesion. I have already mentioned cancer of the lower lip. Still more important, because of their immediate danger to life, are squamous cell cancers of the oral cavity, including the tongue. Their danger arises not only from the fact that the primary lesions are somewhat more difficult to eradicate than those on the lip but also from their mode of metastasis. Metastasis from the lip affects first the lymph nodes of the submaxillary region and subsequently the superficial and deep superior cervical nodes. The lip has no direct connection with the lower cervical and supraclavicular nodes, although they may become involved in late cases. The tongue, how-

ever, has direct lymphatic drainage into all the glands of the neck even down to the supraclavicular and tracheal nodes. Metastases to the latter are early and frequent. Statistics from various clinics indicate that about two thirds of the cancer cases of the cheek, gum of the mandible, floor of the mouth and the tongue have metastases when they first come under observation. It is apparent, therefore, that the matter of primary importance in treatment is the lymph node involvement rather than the original lesion. The first indication in all cases of cancer of the oral cavity, including those of the tongue, is to give thorough roentgen irradiation by the fractionated method over both sides of the neck from the submaxillary to the supraclavicular region. This will occupy a period of at least three weeks, during which time efforts should be made to clean up infections in the mouth and to treat any intercurrent disease, such as syphilis, which interferes greatly with the healing of cancer. At the end of about a month from the beginning of the roentgen treatment the local lesion may be dealt with by implantation of highly filtered radon or radium element, or by electrothermic destruction. After about three months, when the roentgen reaction has entirely subsided, any palpable nodes in the neck may be destroyed by implantation of radon or radium through an incision. Statistics are becoming available from numerous clinics which indicate a great improvement in the results of treatment of intra-oral cancer. Whereas the best results of surgery in good hands is from 10 to 20 per cent of cures in operable cases, reports of radium and roentgen treatment indicate that from 20 to 35 per cent of cure in all cases may be expected, including those that are inoperable. It seems reasonable to believe that results will be somewhat further improved by the general use of thorough roentgen treatment by the fractional method preliminary to treatment of the primary lesion.

Another region in which epidermoid cancer is common is the tonsil, where surgical treatment is hopeless. There is no doubt that primary regression of these malignant growths and at the same time complete disappearance of cervical nodes may be brought about by prolonged fractionated roentgen irradiation. What percentage of permanent cures can be expected is as yet unknown, but squamous cell carcinoma of the tonsil, even with glandular involvement, is no longer a hopeless disease. The lymphosarcomas and the so-called lympho-epitheliomas of the tonsil are among the most radiosensitive of all tumors, and their complete regression along with any glandular extensions may be secured by relatively small doses of roentgen radiation. They metastasize very early, however, and unless they can be treated before this takes place there is little chance for ultimate cure. A somewhat more hopeful class of tumors for radiation therapy, which occur in the tonsil and the parotid, are the mixed cell tumors of embryonic origin. External irradiation is the method of choice in their treatment.

The great majority of cancers of the larynx, especially those which arise entirely within the larynx, are squamous cell epitheliomas. A real advance has been made in the treatment of these cases by the use of the Coutard method. The use of radium within the larynx has always been hampered by the danger of injury to the cartilages whenever the dosage was sufficient to destroy the cancer. Many reports have been published recently of good results obtained by external irradiation

by the prolonged fractional method. Even in far advanced, inoperable cancer of the larynx much good can be accomplished. In early cases the indications now are that the percentage of cures by irradiation will compare so favorably with those for radical operation that the disability due to the latter may be avoided in the future.

A very inadequate picture of the present use of radiation therapy in epidermoid cancer would be presented were consideration of cancer of the uterine cervix to be omitted. A small percentage of cancers in that location are adenocarcinomas, but the great majority are squamous cell epitheliomas. Irradiation is now the generally accepted treatment for all cases of cancer of the cervix. A great variety of methods of applying radiation therapy in this region have been used. The following general procedure recommended by William P. Healy, which is now widely used, has gradually evolved from extensive experience. It is not suggested that it is the only effective method, but it has been found highly successful in practice and is in accord with present knowledge of the action of radiation in cancer.

- 1 Roentgen irradiation of the entire pelvis with high voltage and heavy filtration, spread over suitable time. This recognizes the importance of dealing first with metastases into the regional lymphatic areas and of preventing dissemination of the disease from subsequent manipulation of the local lesion.

- 2 Approximately ten days after completion of the roentgen series the radium treatment in the vagina and cervix is begun. Applicators containing radon or radium well filtered (0.5 mm of platinum or equivalent and rubber) are placed against the cervix and in the lateral fornices for a total dosage of from 3,000 to 4,000 millicurie or milligram hours. This deals with the superficial cervical lesion and extensions into the base of each broad ligament.

- 3 A day or two after the vaginal application, tubes in tandem are inserted into the cervical and uterine canal for a total dosage of about 3,000 millicurie or milligram hours.

- 4 About a month or six weeks after the beginning of the treatment the patient is carefully examined for any small remaining lesions and these are treated by the interstitial application of radon seeds or small radium needles.

Emphasis must be laid on the necessity for the utmost care in carrying through the radiation treatment in all its details, external roentgen irradiation must be thorough, the vaginal applicators must be so applied that the cervix and bases of the broad ligaments receive adequate dosage but with care to avoid damage to the bladder and the rectum, intra-uterine applicators must be so inserted that extension of the disease into the fundus will receive adequate dosage and, finally, any remaining uncured lesions must receive interstitial irradiation.

After this primary course of irradiation further radiation treatment is almost absolutely contraindicated. If the disease recurs, further irradiation is likely to cause irreparable damage to the bladder or rectum. Everything that is to be accomplished should be done at the first series of treatments.

The results of radiation therapy in cervical carcinoma constitute a great advance over previous methods of treatment, and these results are constantly improving as experience accumulates. There is quite general agreement that external roentgen therapy is of distinct value and that its use is resulting in an increased percentage of cures.

Up to this point I have considered only the epidermoid type of carcinoma. Most of the principles involved in radiation therapy of cancer are illustrated by the methods employed in the epitheliomas, which I have discussed, but some of the special problems of radiation therapy can be set forth more clearly by a brief consideration of a few other types of cancer.

Cancer of the breast until very recently was subjected to radiotherapy only when hopelessly inoperable or as a postoperative measure. The fact that about 70 per cent of the total number of breast cancers are not curable by surgical means presents a constant challenge for the persistent trial and development of radiotherapy, the only other means that at present offers any hope for the cure of cancer.

The following points with regard to the treatment of carcinoma of the breast are now quite generally accepted among experienced radiotherapists:

- 1 The initial treatment in all cases of breast carcinoma should be a thorough course of high voltage roentgen irradiation over the breast and lymphatic drainage areas, a total dosage of about 5,000 roentgens spread over at least three areas over a period of twenty-one days.

- 2 If the tumor is inoperable because of fixation, extensive glandular involvement, the age of the patient or the type of the cancer (inflammatory type, cancer en cuirasse or acute duct carcinoma), the subsequent treatment will depend on the condition present from six to eight weeks after the roentgen treatment. In very extensive involvement the palliation resulting from the initial treatment may be all that it is possible to accomplish. In others it is often possible to destroy localized nodules or ulcer by interstitial application of radon or radium. Much can be accomplished in seemingly hopeless conditions for the comfort of the patient and prolongation of life.

- 3 If the tumor is operable, the logical time for operation is from six to eight weeks after the roentgen irradiation. Nothing but good is accomplished by this delay, the devitalization of cancer cells and sealing of the vascular channels greatly lessens the liability of dissemination of the disease at the time of operation. Preoperative irradiation in breast cancer as a routine measure is undoubtedly a real advance in treatment of this disease. When the roentgen treatment is administered by the Coutard method, the injury to normal structures is not such as to create any difficulties or untoward complications in the operation.

- 4 The question of postoperative irradiation is in a somewhat unsettled condition at present. There is good evidence that it has substantially increased the percentage of cures over what is possible with the radical breast operation alone. Now that the more rational method of preoperative irradiation is coming into use, the question must arise as to the necessity for additional irradiation after operation. If the preoperative irradiation has been given to the point of maximum tolerance, as it should be in all cases, care must be exercised in administering subsequent radiation therapy. The important point is that the total amount of radiation, preoperative and postoperative combined, must remain well within the tolerance of the normal structures.

There remain to consider the types of cancer in which very few cures have been reported, those in which only palliation may be expected and those in which radiation has no beneficial effect whatever.

In the first class are cancers of the urinary bladder, in which Burnham has reported 20.5 per cent of cures by a combination of external and implantation radiation. Good results have been reported by Barringer by suprapubic implantation of radium, and a considerable number of cures are also reported by roentgen irradiation alone by the newer fractional dosage. There seems

no doubt that further improvement in results may be expected from combined radiologic methods in these distressing and difficult cases of cancer of the bladder. Lately Waters has reported hopeful results in preoperative roentgen treatment of hypernephroma and carcinoma of the kidney.

In the great field of malignant bone tumors, irradiation has made little headway except as a palliative and to control pain in metastatic carcinoma. Osteogenic sarcoma appears to be completely radioresistant. The only radiosensitive primary bone tumor in the malignant group is Ewing's endothelioma, complete cure however, is difficult because of its tendency to distant metastasis.

Other fields in which irradiation has made little headway are bronchiogenic carcinoma, carcinomas of the gastro-intestinal tract, including the esophagus, stomach and rectum, and malignant disease of the liver or pancreas.

In spite of the large unconquered field, there is ground for much satisfaction in the improvement that has taken place in the treatment of cancer by irradiation in the years immediately past. The percentage of cures in a number of the most dangerous of the epidermoid cancers has been markedly increased and some that were formerly entirely hopeless now show a substantial number of cures.

#### PROGRESS IN KNOWLEDGE OF CANCER

The principal additions to knowledge in recent years which have improved results in the fight against cancer may be summarized as follows:

- 1 The fractional method of roentgen irradiation with high voltage, heavy filtration and protracted time of administration has been perfected and constitutes an important advance.

- 2 A better understanding has developed concerning the role of the normal tissue environment of a malignant growth and the necessity of securing a proper relation between destruction of the cancer cells and reaction in the cancer bed.

- 3 There is a gradually increasing knowledge of the value of preoperative irradiation.

- 4 A better appreciation is evident concerning the danger of traumatizing a cancer and also of the fact that such danger can be lessened by preliminary irradiation.

- 5 There is a better grasp of the role of the regional lymph nodes and of the necessity to preserve them as intact as possible as a barrier to the spread of cancer cells, and at the same time to destroy cancer cells already lodged there.

Hope for further advance in the immediate future lies in increased application of the knowledge already at hand. Early diagnosis and treatment are just as important for radiation therapy as in surgery, although many patients with far advanced cancers which are hopeless for surgery may be cured or materially benefited by radiation treatment. It is particularly important that cancer patients be given the benefit of the latest methods of radiation therapy, especially in those conditions in which surgery has been used for many years and has shown only a small percentage of permanent cures.

There is also hope that improvements in roentgen apparatus which permit a better relation between destruction of malignant cells and effects on normal tissues will bring an additional number of cancer cases into the curable range.

## Therapeutics

### THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.  
CHICAGO

*NOTE—In their elaboration these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics Dr. Bernard Fantus. The views expressed by various members are incorporated in the final draft for publication. The series of articles will be continued from time to time in these columns.—ED*

#### THERAPY OF DISTURBANCES DUE TO HEAT

Excessive exposure to heat is liable to result in one of three rather specific conditions: heat cramps, heat prostration or heat stroke. In addition to these, it must be appreciated that, when a person is exposed to excessively high external temperature, a strain is put on the entire system, most especially the circulatory mechanism and the excretories, so that persons handicapped by almost any systemic disease are prone to suffer from an aggravation of their symptoms entirely because of this functional strain. All such persons are in greater need of protection against such exposures than are normal persons and they can be relieved of distresses due to heat exposure, even though the distresses are not of a specific type, by measures directed against the excessive heat and its results rather than by digitalis, diuretics or hypnotics that might otherwise seem indicated. Even relatively normal persons differ greatly in their ability to tolerate heat. Least able to do this are the very young, the very old and the obese. Alcohol addicts and persons who have once had sunstroke are particularly predisposed and require especial protection.

#### PROPHYLAXIS

Preventive treatment is identical for the various disturbances due to excessive heat. It must embrace (1) increasing heat elimination, (2) lessening heat production and (3) minimizing exposure to heat, while (4) maintaining the heat regulating center in optimum functional condition.

1 When the human body must maintain its normal temperature in spite of an external heat near to or even above that of the system, its chief defense is the evaporation of sweat. Therefore the production of sweat should be favored. This requires the ingestion of an abundance of water, maybe from twelve to fifteen glasses a day. The frequent taking of small quantities is better than of large drinks at long intervals. This is especially true when the circulation is enfeebled. Carbonated drinks are preferable because they leave the stomach more rapidly, as the stomach does not absorb water. Profuse sweating robs the body of large amounts of salt. As much as 2 or 3 Gm. may be lost in an hour. Therefore sodium chloride should be taken in unusual amounts (from 15 to 20 Gm. daily) with the food or the drink, a level teaspoonful to a quart of water or a 1 Gm. tablet of sodium chloride with each tumblerful. This becomes less necessary after acclimatization has occurred, which in part consists of the ability to secrete extremely dilute sweat. The liberal use of fruit juices is particularly important when it is also

necessary to maintain good kidney elimination, for the fruit acids direct some of the water to go out in this way.

When sweat production is not free enough, the skin—most especially the head and hair—should be kept wet with cold water, and frequent cool baths may be required.

Sweat cools a person only when it evaporates. The sweat that runs off "in streams" is lost as far as heat regulation is concerned. Sweat evaporation must therefore be favored by loose, light, thin, nonconstricting clothing or practically no clothing at all and by exposure to air currents produced by fans or between open shaded windows.

2 Heat production should be minimized by reducing muscular exertion as much as possible when the heat is intense. The midday siesta is a hygienic necessity in hot climates. Work should be done in the cooler part of the day. Work that must be done during very hot weather should be carried on in short periods alternating with rest.

Food should be light and highly digestible, moderate in amount and largely consisting of carbohydrate, with avoidance of fats (because of their high caloric value) and of protein because of the large amount of heat freed during its assimilation. Juicy fruits should be especially favored.

3 Exposure to the direct rays of the sun should be avoided, for the visible and the ultraviolet rays are the most dangerous, especially when they impinge directly on the head. Should such exposure be unavoidable, tropical helmets should be worn. Forced marching in heat and sunshine should be done in open formation so as to prevent heat and humidity stagnation, and it necessitates frequent halts in the shade. During a halt one should, if possible, avoid resting directly on the ground, for the air just above the sunned ground is hottest.

4 The heat regulating mechanism should be protected against intoxication by liquor and other narcotics, as well as by coffee or tea, or tobacco, for all these have an unfavorable effect on it and, in the last analysis, on the heat regulating center devolves the business of maintaining the normal body temperature.

#### TREATMENT

*Heat Cramps* (stoker's cramps).—These painful spasms, particularly of the abdominal muscles and of the extremities but which may be generalized so as to simulate epilepsy, are induced by excessive sweating due to hard labor in furnace rooms, foundries or such places. They are usually accompanied by pallor, nausea, dizziness and mental depression. The pulse is rapid but strong and the temperature is normal.

The three fundamental indications in all heat induced disturbances are removal of the patient to the coolest place available, rest in the recumbent posture, and the supplying of salt and water. The patient should be encouraged to quench his thirst with salt solution (a level teaspoonful to a quart). He should, in addition, receive by rectum as much as he can retain by slow rectal injection of 1 per cent sodium chloride solution. If the symptoms are urgent, Physiologic Solution of Sodium Chloride may be injected by hypodermoclysis and even by phleboclysis, for which 5 per cent of dextrose may possibly be added to advantage. Milk, orangeade and lemonade should be given every two hours.

As this treatment does not give complete relief from the muscle cramps for a few hours, there is no sense in withholding a hypodermic injection of morphine (10 mg) for prompter action, if the pains are severe. If convulsions are present Chloral Hydrate 1 Gm and Sodium Bromide 2 Gm should be given by mouth or in starch water by rectum, and repeated in four hours if required. If they are very severe, sufficient chloroform should be used to produce muscular relaxation at once and this may be repeated as required.

*Chloral and Bromide*

R Chloral hydrate	15 00 Gm
Sodium bromide	30 00 Gm
Fluidextract of glycyrrhiza	30 00 cc
Water	to make 60 00 cc
M Label Teaspoonful in milk every four hours as required (For restlessness or convulsions)	

**Heat Prostration** (heat exhaustion) —The symptoms of depression of the nervous system and of collapse predominate. The temperature is usually normal or even subnormal. It seldom exceeds 101 F. The onset may be sudden and it may occur even hours after the exposure. Recovery may not be prompt, but it is usually complete, excepting of course for preexisting disease, which is often present.

To the three fundamental indications as outlined in the treatment of heat cramps should be added stimulation (a) Caffeme Sodio-Benzate from 0.25 to 0.50 Gm, should be injected subcutaneously every four hours, alternating with (b) Strychnine Sulphate, 2 mg every four hours, if there is no tendency to convulsions. (c) Strophanthin, 0.5 mg, should be given intravenously if the pulse is very rapid, but this should not be repeated for twenty-four hours. (d) Camphor in oil, 2 cc intramuscularly, or metrazol, 1 cc, intravenously may be used if there is no excitation state. (e) Aromatic Spirit of Ammonia, 1 cc in water by mouth, by intramuscular injection or by inhalation, should be given. Its prompt though fleeting effect may favor the absorption of a hypodermically deposited stimulant.

If the body temperature is subnormal, warm baths and hot drinks should be given, but with care to avoid sudden induction of a high temperature. If the temperature is above 102 F it should be reduced to this point by "cool ablution," as described under Fever Regimen.

Preexisting disease accompanying the condition should be taken cognizance of, as it may modify the treatment. It is the dominant factor in the after-care.

**Heat Stroke** (sun stroke) —Pyrexia predominates. The onset may be gradual with mental excitement or depression, dryness of the mouth and skin, dizziness and headache, and frequent micturition. It may be sudden, the patient being struck down with delirium, stupor or coma and a hyperpyrexia (temperature up to 107-110 F) with an intensely hot skin, which is usually dry but may be moist. In the semicomatose patient the superficial reflexes are abolished, in the comatose, all reflexes are absent.

To avoid erroneously treating sudden prostration from pernicious malaria for heat stroke, blood examination should be made as a routine procedure in malarial districts.

In the treatment of sunstroke, one must add to the three fundamental measures described under heat cramps, most especially while plying the patient with the administration of fluid and some salt, the reduction of the hyperpyrexia. This assumes the greater importance the higher the temperature.

The procedure that should be employed at once wherever the patient is found, is to lay the patient in the coolest possible shady place on a table or otherwise keeping him off the ground, the head elevated, applying cold compresses to the head and neck continually, to remove most of the clothing and to sprinkle the patient with a sprinkling can or watering hose, while maintaining a constant current of air by fanning and keeping the blood in the skin by vigorous friction. This process should be kept up until the temperature taken by rectum every few minutes, is reduced to 102 F, or, in the absence of a thermometer, until the skin does not warm up as readily under the friction as it did at first.

The patient should then be transported to the hospital while wrapped in a wet sheet or in wet clothing, with compresses (maintained cold by frequent changing) applied to the head, which should be elevated.

In the hospital, an ice bag should be applied to the head and neck, the head kept elevated, and, if the temperature has risen, a "cold sprinkling sheet bath," as described under Fever Regimen, should be administered. In this procedure, practicing friction continuously and maintaining a constant current of air, preferably by means of an electric fan, is of great importance. Properly given, it is probably superior to the tub bath and much less troublesome. It should be repeated whenever the high temperature recurs, most especially if sweating, once reestablished, ceases. The "sheet rub with ice" might be resorted to in cases presenting an obstinate high temperature. More drastic cooling procedures, such as packing in ice, ice water baths, ice water enemas or ice water gastric lavage, should not be employed, owing to the danger of producing collapse.

These patients should be watched continuously, owing to the danger of recurrence of hyperthermia until consciousness has returned and the temperature stays about 99 F for a few hours.

If the cerebrospinal pressure is found increased, it should be reduced by lumbar puncture, from 30 to 40 cc of cerebrospinal fluid or as much as necessary being slowly abstracted and this being repeated as required. Abstraction of from 400 to 500 cc of blood by venesection or by means of leeches applied to the temples and mastoids is especially indicated in the asphyxial form with cyanosis, distention of the veins and most particularly if there are signs of pulmonary edema.

Stimulation may be indicated by severe depression of the circulation. But stimulants should not be used unless absolutely required, as there is a tendency in heat stroke for extravasations of blood to occur in the brain, meninges or heart. It is these that are responsible chiefly for complications or sequelae, and they may be aggravated by too great a circulatory activity.

Artificial respiration is demanded by respiratory failure and it should be kept up until all hope of resuscitation must be abandoned. Rhythmic traction of the tongue may be employed from time to time to provoke, if possible, spontaneous respiration.

Prolonged bed treatment is required during the convalescence, as it may take many days to recover from the effect of extravasations that may have occurred in the vital organs. Living in a cool climate and absolute prohibition of alcohol are essential in the subsequent conduct of life of the survivors from sunstroke, because of the well known difficulties experienced by them in subsequent exposures to heat.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT  
H. A. CARTER, Secretary

### VESTVOLD'S ORIFICIAL MAGNO-VIBRATOR NOT ACCEPTABLE

The Vestvold's Orificial Magno-Vibrator is manufactured by R. F. Vestvold, Haverford, Pa. It looks like a cylinder three-fourths inch in diameter and 7 inches long over all, with a conical tip and an electric cord connection at the other end. When the cord is attached to a source of alternating current, a vibratory force is set up.

The firm claims that this unit gives instant relief in asthma, stimulates nerve function, and induces sleep. It is also stated that the 'Magno-Vibrator breaks up construction of rectal tissue and spastic sphincter muscles, an excellent adjunct in the relief of constipation when due to this cause.' Among some of the effects of the magnetic applications, according to the firm, is that "mineral elements of the body, particularly the iron become charged with magnetic force which is distributed by the blood stream uniformly throughout the entire system. Iron acts as a catalyzer, uniting the oxygen to the cell (oxidation). That an added magnetic charge increases oxidation has been proven by clinical results." The claim that it sets up an alternating magnetic stress is not explained.

One unit was tested in a clinic acceptable to the Council. The investigation revealed nothing so far as its therapeutic efficacy was concerned. Furthermore the claims for the device recorded in the advertising matter were unwarranted, misleading and exaggerated. The Council omitted the Vestvold's Orificial Magno-Vibrator from the list of accepted devices.

### VESTVOLD'S PHOTO-ELECTRIC DILATOR NOT ACCEPTABLE

The Vestvold's Photo Electric Dilator, manufactured by R. F. Vestvold, Haverford, Pa. is said to be useful for applying heat and electrical energy in rectal, prostatic and vaginal disorders. The unit is approximately 8 inches long and three-fourths inch in diameter and the assembly may be attached to an ordinary light socket. The surface metal looks like polished aluminum.

In the promotional literature for this outfit the following statements are recorded:

Here is a way to administer soothing safe and controlled heat (infra red rays) in a direct way. Besides the well known virtue of heat you have in this dilator a photo electric effect (conversion of light into electrical energy) this combination of heat and the steady flow of electrical (non shock) energy you will find is an excellent treatment for many Rectal and Vaginal Disorders its emanations are instantly absorbed by the tissues.

With the Photo Electric Dilator Vaginal, and Uterine Disorders are usually treated through the rectum.

The Photo Electric Dilator is used with the blood pressure as an indicator and is especially recommended in the treatment of hemorrhoids, menstrual disorders and prostatitis.

In addition to specific relief for the conditions indicated above treatment with this dilator brings about a general relaxing of the nervous system and often relieves such symptoms as headaches, mental depression, nervousness, backache and frequent urination.

Just the thing for the busy practitioner. No waiting for the Photo Electric Dilator to get hot it is ready for use in a minute's time after it has been plugged in on the electric circuit.

The unit was examined in a clinic acceptable to the Council. The report reads as follows:

The instrument is called a Photo-Electric Dilator. This name is regarded as a misnomer. The circular contains a parenthetical statement implying that this instrument converts light into electric energy, or makes use of the photo electric effect. Farther along the directions explain that this particular instrument works by plugging it into an electric circuit. It seems, therefore, that one deals with electric energy directly as converted into heat. There is no attachment through which light energy is converted into electric energy. This instrument has a red light in series which works, apparently, as a rheostat

and this light does actually convert electric energy into light, but so far as can be determined it has nothing to do with any therapeutic action.

It is difficult to understand how this instrument can give specific relief for hemorrhoids, menstrual disorders, prostatic trouble, headache, mental depression, backache, and frequency of urination. It is difficult to perceive how this instrument effects a cure of backache due, for example, to tuberculosis of the spine, or how it cures frequency of urination due to a stone in the bladder, or frequency due to or associated with tuberculosis of the bladder and kidneys.

The use of heat by rectum as an adjunct to other forms of treatment in cases of infections of the prostate gland and seminal vesicles has been recognized for many years. The heat may be supplied by hot rectal irrigations. The statement is made in the circular that the heater supplies heat to the prostate, and this is probably true. However, the claim that applying heat through the vagina or heat through the rectum can cure mental depression is questionable. In other words, instruments of this kind supply heat to the prostate through the rectum and as such they may be valuable adjuncts.

Because the aforementioned claims for the unit have not been substantiated by critical evidence and since they are regarded as unwarranted, exaggerated or misleading, the Council voted to omit the Vestvold's Photo Electric Dilator from the list of accepted devices.

## Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT  
RAYMOND HERTWIG, Secretary

### ACCEPTANCE WITHDRAWN PROTEO BREAD

Distributor—Proteo Foods, Inc., Chicago

Manufacturer—Holsum Bakery Co., Fort Wayne, Ind.

Description—Bread prepared from water, gluten, soy bean and whole wheat flours, skim milk, yeast, fat, egg, casein salt calcium-acid phosphate and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate.

Analysis (submitted by distributor) —	per cent
Moisture (entire loaf)	38.0
Asli	3.0
Fat	8.0
Protein (N $\times$ 6.25)	24.1
Reducing sugar as dextrose	2.5
Sucrose	0.0
Starch (diastase method)	16.0
Dextrins (acid hydrolysis)	2.0
Pentosans	2.2
Crude fiber	1.3
Carbohydrates available	20.5
Carbohydrates available and nonavailable other than crude fiber (by difference)	25.8
Calcium (Ca)	0.21
Phosphorus (P)	0.39
Iron (Fe)	0.005

Calories—27 per gram 77 per ounce

Discussion—On the basis of the recently adopted General Decision Special Purpose Foods for Diets Restricted in Dextrose Formers (THE JOURNAL, Sept. 1, 1934 p. 681), the previous acceptance of Proteo Bread is being withdrawn. Under this decision it is required that special breads intended for diets restricted in dextrose formers, to be eligible for acceptance, shall contain dextrose formers in an amount not greater than 3.3 Gm of dextrose per hundred cubic centimeters (the dextrose equivalence being computed as the carbohydrate, plus 58 per cent of the protein, plus 10 per cent of the fat content of the food). Proteo Bread furnishes approximately 10 Gm of dextrose per hundred cubic centimeters.

The label and advertising represent Proteo Bread as a special purpose bread particularly adapted for use in diets of the diabetic and the obese patient for the plausible reason the bread is "rich in essential proteins" and "lower in carbohydrates (starches and sugars) than ordinary bread most so called gluten and soy bean breads." The caloric content of the bread is so high that it is not suitable

for the patient with obesity as claimed and as implied by the syphilitic figure on the label and in the advertising. The fact that the high protein content of the bread yields large quantities of dextrose in metabolism is disregarded. This high ultimate yield of dextrose disqualifies the bread for its alleged usefulness as a special food for patients with diabetes. The following claims are the basis of the advertising:

(Label) Proteo Bread for diets restricted in starches and sugars rich in essential proteins. Proteo Bread is lower in carbohydrates (starches and sugars) than ordinary breads and lower than most so-called gluten and soy bean breads baked especially for those whose diets must be carefully restricted in carbohydrates.

(Advertising) A bread food prepared especially for carbohydrate restricted diets and used successfully in diets for diabetes, arthritis and obesity. Patients respond gratefully to this appetizing and nutritious food. A slice or two of Proteo Bread will take the place of other more fattening foods.

There is authoritative evidence that commercially prepared special diabetic foods are limited in usefulness to the diabetic patient in that the availability of insulin makes them no longer necessary. The designation of a food as a diabetic food merely because it is low in carbohydrates is now unwarranted and misleading, and gives the erroneous impression either that the food taken in unrestricted quantities in diabetes is harmless or that it has remedial action. Protein may be tolerated almost as poorly as starch by the diabetic patient.

The advertising for Proteo Bread is badly misinformative and deceptive. The bread has no specific value or usefulness in diabetic reducing or ketogenic diets, since volume for volume it contributes approximately as much of dextrose formers to the diet as ordinary white bread. This product therefore will no longer be listed among the Committee's accepted foods.

#### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary

##### (A) TEMPLE STEPHENS BRAND CRYSTAL WHITE SYRUP

##### (B) TEMPLE STEPHENS BRAND GOLDEN SYRUP

*Distributor*—Temple Stephens Company, Moberly, Mo.

*Packer*—Penick & Ford Sales Company, Inc., Cedar Rapids, Iowa.

*Description*—(A) Table syrup, corn syrup sweetened with sucrose. The same as Penick Crystal White Syrup. *THE JOURNAL*, April 9, 1932, page 1268.

(B) Table syrup, corn syrup flavored with refiners' syrup. The same as Penick Golden Syrup. *THE JOURNAL*, April 2, 1932, page 1159.

*Claims of Manufacturer*—Recommended for use as an easily digestible and readily assimilable carbohydrate supplement to milk in infant feeding and as a syrup for cooking, baking and the table.

##### SUNSWET JUICE OF THE DRIED PRUNE (WITH WATER ADDED)

*Manufacturer*—California Prune and Apricot Growers Association, San Jose, Calif.

*Description*—Pasteurized water extract of dried prunes.

*Manufacture*—Dried prunes are immersed in hot water to dissolve or soften outside organic matter, thoroughly washed, placed in boiling water for from three to five minutes, transferred to a steam jacketed kettle and simmered for two and one-half hours in twice their weight of water, which is drawn off. The drained prunes are boiled for fifteen minutes in a second batch of water. The prunes are removed and the liquid content

is expressed in a cider press. The pulp is boiled in water removed and again pressed. The resulting expressed fluids and water extracts are blended, standardized to 19 per cent sugar content by the addition of water or prune extract concentrate during which time the temperature is maintained at 88 C, filled into bottles, pasteurized for twenty-five minutes at 86 C and cooled.

#### Analysis (submitted by manufacturer) —

	per cent
Moisture	82.7
Ash	0.3
Fat (ether extract)	0.02
Protein (N X 6.25)	0.4
Reducing sugars as invert sugar	12.0
Sucrose	0.6
Crude fiber	0.0
Carbohydrates (by difference)	16.4
Titratable acidity as malic acid	0.2
Aluminum (Al)	0.001
Calcium (Ca)	0.01
Chlorine (Cl)	0.003
Copper (Cu)	0.0003
Iron (Fe)	0.003
Magnesium (Mg)	0.01
Manganese (Mn)	0.00005
Phosphorus (P)	0.02
Potassium (K)	0.17
Silicon (Si)	0.002
Sodium (Na)	0.01
Sulphur (S)	0.008

Calories—0.7 per gram, 20 per ounce.

*Claims of Manufacturer*—Gently laxative. No added sugar or preservative.

#### ILLINOIS VALLEY VITAMIN D FORTIFIED PASTEURIZED HOMOGENIZED MILK

*Distributor*—Illinois Valley Ice Cream Company, Streator, Ill.

*Description*—Bottled pasteurized homogenized milk fortified with vitamin D (vitamin D concentrate prepared from cod liver oil), contains 400 U. S. P. X (Revised, 1934) vitamin D units per quart.

*Preparation*—The milk complies with legal requirements, is pasteurized by the standard holding method, and is homogenized at a pressure of 2,500 pounds per square inch. See *THE JOURNAL*, July 1, 1933, page 34, for description of fortification with vitamin D.

*Vitamins*—The vitamin D concentrate used and the fortified milk are regularly tested biologically. Clinical investigation shows this milk to be a reliable antirachitic agent if the proper amount is used.

*Claims of Distributor*—A vitamin D fortified antirachitic pasteurized homogenized milk having otherwise the flavor and food values of usual pasteurized milk. The cream does not separate.

#### HAWAIIAN FINEST QUALITY PINEAPPLE WAPCO BRAND BROKEN SLICES (VACUUM PACKED), GRATED SLICED (VACUUM PACKED), TIDBITS (VACUUM PACKED)

#### WHITE SWAN BRAND SLICED (VACUUM PACKED), CRUSHED, GRATED

*Distributor*—Waples Platter Grocery Company, Fort Worth, Texas.

*Packer*—Hawaiian Pineapple Co., Ltd., San Francisco.

*Description*—Canned pineapple packed in concentrated pineapple juice with added sucrose. The same as Dole Hawaiian canned pineapple products. *THE JOURNAL*, April 8, 1933, page 1106 and April 29, 1933, page 1338.

#### QUAKER BRAND GELATIN VOGT BRAND GELATIN

*Distributor*—Cherry-Burrell Corporation, Chicago.

*Packer*—Swift and Company, Chicago.

*Description*—Granular plain gelatin, unsweetened and unflavored. The same as Swift's Gelatins. *THE JOURNAL*, Jan. 16, 1932, page 231.

## NUTRITION AND RESISTANCE TO INFECTION

During the last thirty years the science of nutrition has shown such a rapid and sound development that at present it is accepted as one of the disciplines on which depends the welfare of man and his domestic animals. The intimate relation of nutrition to such processes as growth, reproduction and activity is taken for granted. As a logical outgrowth of the extensive investigation on which this point of view rests, it is now common to hear diet referred to as one of the important factors in preventive medicine. It can readily be demonstrated that such features of physiologic economy as acid-base balance, deficiency diseases and bone development are more or less closely associated with diet, the effect of nutrition on resistance to infection is not so obvious, although the mass of alleged evidence is enormous. Clausen<sup>1</sup> has recently reviewed the subject, confining himself to a consideration of infections of bacterial origin.

A survey of the results of studies designed to demonstrate the influence of diet on the transmission of antibodies by way of colostrum and milk as well as on the level of antibodies in the serum shows much confusion and little evidence for the thesis. In discussing the resistance of tissues to infection, it is pointed out that more carefully planned experiments are necessary before definite conclusions can be reached. It does appear, however, that scurvy lowers the resistance of guinea-pigs to tuberculosis and that a deficiency of vitamin A may decrease it in the rat and mouse. Clinical observations have been exceedingly difficult to interpret and there is little convincing evidence that there exists a specific relation between the recognized dietary factors and resistance to tuberculosis in man. Throughout Clausen's discussion it is evident that in human experience the available information of the infection invariably far exceeds the knowledge of the dietary fault involved and that conclusions are made difficult, in addition, by the inability to subject patients to controlled nutritional programs.

Another extensive survey with emphasis on the relation of the vitamins to resistance to infection has been written by Robertson<sup>2</sup>. The available evidence was subjected to four criteria: determination of any change in natural immune bodies or cellular reactions due to the deficiency, the evaluation of antibody responses after injection of appropriate antigens into experimental animals, the liability to spontaneous infection shown by poorly fed animals, and the susceptibility of individuals maintained on inadequate rations to experimentally induced infections. Despite the fact that vitamin A is called the anti-infective vitamin, there is a paucity of really cogent experimental results or clinical observations regarding this alleged function of vitamin A. It is concluded from the summary both of immunologic studies and of spontaneous infections that rachitic animals are more susceptible than are normal ones to spontaneous as well as artificially induced infections. Judged by immunologic reactions, neither scurvy nor deficiency in vitamin B is attended by consistent variations in resistance to infection. It has not been shown that, in early vitamin B deficiency before symptoms become severe, there is a decrease in resistance to artificially induced infections.

It should be borne in mind that these reviews have approached the subject of infection as a more or less specific biologic phenomenon. Secondary infections commonly seen after tissue damage has been brought about by the dietary deficiency are not considered in evaluating the evidence. Despite the many demonstrated correlations between lack of an essential dietary factor and functional and structural change in the organism, there is surprisingly little cogent evidence of a specific relation between these factors and infection.

## CYSTEINE AND THE TENDENCY TO HEMORRHAGE IN OBSTRUCTIVE JAUNDICE

Numerous examples may be found in clinical literature demonstrating that an impaired activity of one organ or tissue may produce an abnormal performance of another, often one having an entirely different physiologic function. The tendency to hemorrhage in obstructive jaundice is a typical example. The distinct susceptibility of jaundiced patients to bleeding introduces a grave complicating factor in the treatment of this malady, as surgical intervention, the only satisfactory remedial procedure, may lead to fatal hemorrhage. The observations of Walters<sup>1</sup> several years ago, that the death of more than half of a series of jaundiced patients subsequent to abdominal operation was the result of large intraperitoneal hemorrhage, emphasizes the importance of this complicating feature.

Several theories postulating a deficiency of one of the clotting elements have been advanced to explain the

1 Clausen S W. *Physiol Rev* 14 309 (July) 1934

2 Robertson Elizabeth C. *Medicine* 13 123 (May) 1934  
1 Walters Waltman. *Preoperative Preparation of Patients with Obstructive Jaundice Surg (Gynec & Obst)* 33 651 (Dec) 1921

abnormal mechanism of coagulation in obstructive jaundice, and each in turn has been largely abandoned. The calcium theory has not proved tenable, repeated analyses having shown that the total and "available" serum calcium of jaundiced subjects usually fall within normal limits. Likewise normal values have been obtained for blood platelets, for plasma fibrinogen, for fibrin, and even for the clotting time of the blood itself. Recent investigators, after confirming the foregoing observations both in jaundiced patients and in experimental animals with ligated biliary ducts, have approached the problem from a different angle. The presence in the blood of a positive agent that inhibits the normal clotting mechanism was considered. Such a possibility seemed particularly pertinent in view of the fact that bile is an important excretory medium for a variety of substances which, as a result of biliary obstruction, might accumulate in the blood stream. In support of this view is the fact that in jaundiced patients the blood clot, although forming as rapidly as normal, is large, friable and nonretractile, as though syneresis of the fibrin had been inhibited. In contrast to the normal compact clot, a porous mesh of this kind might permit the seepage of cells and plasma from a damaged blood vessel and thus lead to the slow, persistent exsanguination encountered in cases of obstructive jaundice.

An observation<sup>2</sup> that cysteine inhibits blood coagulation induced Carr and Foote<sup>2</sup> to study the possible relation of this amino acid to the impaired clotting reaction in obstructive jaundice. Preliminary studies demonstrated that the addition of minute amounts of cysteine to normal blood shortened the coagulation time and changed the clot to a large, friable, nonretractile mass closely resembling that formed by the blood of jaundiced human subjects. The injection of large doses of cysteine into normal animals produced a similar effect. Color tests for cysteine demonstrated that none was present in normal plasma, whereas definite reactions were obtained on the plasma from jaundiced animals. Furthermore, the intensity of the test increased progressively with the tendency to hemorrhage.

The foregoing indications that cysteine or perhaps some related mercaptan is intimately related to the abnormal clotting reaction in jaundiced subjects prompted an investigation of the therapeutic action of brombenzene, a substance that combines with cysteine to form bromphenyl-mercapturic acid, excreted in the urine. The tendency toward bleeding was definitely reduced in the treated animals and they did not die of hemorrhage. Crystals of bromphenyl-mercapturic acid were isolated from the urine.

While this investigation is undoubtedly a valuable contribution to the current knowledge of the etiology

of the hemorrhagic tendency in obstructive jaundice, much more experimental work on the subject is needed before conclusions can be drawn. Likewise, although the beneficial action of brombenzene therapy is at least suggestive, it should be recalled that this substance is definitely toxic and should be used with the greatest caution. Perhaps of most immediate clinical import is the suggestion that an excess of protein, the metabolic precursor of cysteine and related mercaptans, should be avoided in the diet of patients with obstructive jaundice.

#### EXCRETION OF UREA

There is a perennial thrill about the search for the final explanation of the mechanism of renal function. Of the recognized organs of excretion, the kidney would seem to have received its full share of attention, further study has only served to emphasize its manifold connection with the physiology of the organism. Ordinarily, renal function is considered primarily in relation to the formation of urine, the concentration and removal of metabolic waste products with the maximum conservation of water. A recent study by Van Slyke, Rhoads, Hiller and Alving<sup>1</sup> bears significantly on this point, the relationships between urea excretion, renal blood flow, renal oxygen consumption and diuresis are considered. The investigation differs from previous ones in that it was carried out on experimental animals in which one kidney was explanted<sup>2</sup> intact directly under the skin, so that simultaneous samples of urine and blood from the renal vein and femoral artery could be obtained without the use of anesthesia.

This study is concerned directly with the factors controlling the urea clearance test,<sup>3</sup> the introduction of which several years ago marked an important advance both in experimental investigations in renal physiology and in the clinical diagnosis of renal disease. In this test the amount of urea excreted per minute is compared with the concentration of urea in the blood, the "clearance" indicates the quantity of blood, in cubic centimeters, the urea content of which is excreted in one minute. In the normal human adult this is about 75 cc. In severe renal disease the urea clearance may be reduced to 5 per cent of the normal value, at which point uremia usually supervenes. But it has been shown that marked variations in blood urea do not significantly affect the result of this test. If the blood urea is higher, the same amount of blood is nevertheless "cleared" of urea, more of the latter being excreted.

The experiments of the Rockefeller investigators were performed on dogs, in all of which one kidney

had been explanted, in some the other organ was removed. Following a fast of twenty-four hours, a solution of sodium chloride in constant proportion per unit of body weight was administered by stomach in order to maintain the rate of urine excretion above the "augmentation limit," that rate below which the blood urea clearance ceases to be independent of urine volume and decreases with decreasing urine output (about 2 cc per minute in man). The observations in each experiment covered three or four successive periods, each of about an hour. The dog was catheterized at the beginning of the experiment and at the end of each period. At about the middle of each interval, blood was drawn from the renal vein, this was followed usually after from two to five minutes by withdrawal of a sample from the femoral artery.

From the values of urea concentration in the blood from the femoral artery and renal vein and the total urea excretion in the urine, not only was the renal blood flow calculated but also the proportion of urea in the blood that was extracted by the kidney. When the blood urea was at the fasting level, from 67 to 106 per cent was extracted, when the arterial blood urea concentration was increased as much as ten times, the extraction values still varied from 86 to 104 per cent. This uniform efficiency in the face of greatly augmented work performed was maintained without a significant increase in renal blood flow. It appears then that the kidney may remove a constant proportion of the urea in the blood flowing through it, regardless of the concentration of urea in that blood within the limits studied. This was found to maintain over a range of from 8 to 137 mg of blood urea nitrogen per hundred cubic centimeters. The mechanism by which the kidney tends to keep the urea clearance at a constant level under these conditions therefore appears not to be dependent on changes in blood flow. However, changes do occur spontaneously in the clearance and these were found to parallel alterations in rate of circulation of blood through the kidney. The latter observations are of interest in view of a recent report by Goldblatt<sup>4</sup> who found in a study of experimental hypertension that mechanical interference with flow through the renal arteries may cause diminution in urea clearance if the flow is sufficiently reduced, but that moderate constriction of the renal arteries sufficient to induce persistent arterial hypertension, may not produce an appreciable change in the clearance.

Van Slyke and his co-workers found in a few instances that blood from the renal vein contained even more urea than that from the femoral artery, observations made before and after these occurrences showed normal comparative levels. Such variations these investigators believe may have been due to reflexes initiated by venipuncture, but it was not found possible to repro-

duce these effects at will. They suggest that this phenomenon, which apparently involves reabsorption, may be an occasional factor in other cases of diminished urea clearance.

Access to blood in the renal vein permits the ready determination of oxygen consumption by the kidney. Removal of one kidney brought about an increase in the oxygen used by the remaining organ, a change that parallels the speeding up of other activities already noted. On the contrary, neither diuresis nor excretion of increased amounts of urea was accompanied by rise in oxygen consumption. Renal blood flow and use of oxygen by the kidney tended to vary in a parallel manner, presumably in response to similar or common metabolic demands. That the cells of the kidney ordinarily require a higher oxygen tension than do most other organs is indicated by the fact that the blood in the renal vein is usually more than 85 per cent oxygenated. After removal of one kidney, observations made one week later showed that the blood flow through the remaining organ was increased about 68 per cent, oxygen consumption rose 81 per cent and urea clearance 43 per cent. Beyond this period no further significant changes were observed, the kidney apparently takes over a large share of the work previously performed by its mate but not all of it.

The studies of the Rockefeller group have demonstrated anew the efficiency of the kidney, as far as the excretion of urea is concerned, and facile adjustments, which permit the maintenance of renal function after unilateral nephrectomy. The observations made under experimental physiologic conditions so little removed from normal provide a point of departure for elucidation of the details of abnormal renal activity.

## Current Comment

### PHYSICAL ALLERGY

The problems of physical allergy, particularly the relationship of cold to sensitivity, are under investigation in many places. The manifestations are striking and, to the patient, a serious problem. A survey of the available literature on the subject offers some interesting comments by older observers. Thus, Salter<sup>1</sup> in 1882 said in commenting on asthma: "Until lately I felt no doubt that the asthma was, in these instances, a mere reflex nervous phenomenon, but of late I have seen some cases, not asthmatic, that have shown me how quickly—how immediately, indeed—cold to the surface and extremities may derange the vascular balance of the bronchial mucous membrane, and which suggest, therefore, that even in these asthmatic cases the vascular condition of the bronchial mucous membrane may be the link between the external cold and the bronchial spasm." A case of urticaria due to cold was reported

<sup>4</sup> Goldblatt, Harry, Lynch, James, Hanzal, R. F. and Summerville, W. W. *J. Exper. Med.* 59: 347 (March) 1934. An investigation into the Cause of Hypertension. Editorial. *J. A. M. A.* 102: 1610 (May 12) 1934.

<sup>1</sup> Salter, Hyde. *Asthma Its Pathology and Treatment* first American Edition 1882.

by Fraser<sup>2</sup> in 1905, and in the same year Osler<sup>3</sup> noted urticaria due to exposure to cold. Moreover, Ward<sup>4</sup> in 1905 mentioned a patient who was sensitive to certain spectrums of the sun's rays but not sensitive to heat. At the same time he described a patient subject to angioneurotic swellings on exposure to cold and said that he had observed this phenomenon since 1880. Thus physical allergy has been definitely recognized for about three quarters of a century. If sensitivity to light is included, it is found that Bazin<sup>5</sup> mentioned a disease entity of the skin caused by sensitiveness to light in 1855, an observation that was subsequently confirmed by Hutchinson<sup>6</sup> and by White.<sup>7</sup> THE JOURNAL<sup>8</sup> called attention to the importance of sensitivity to cold as a cause of sudden death in drowning. Now that the possibility of severe bodily reactions from heat, cold, light and other physical agents has been so definitely established, the explanation for many unexplainable symptoms may become apparent.

### Medical Economics

#### ALAMEDA COUNTY (CALIF.) PLAN

Before any plan was adopted, the Alameda County Medical Association undertook a study to determine the best method of providing medical care for three classes of the population: (1) the indigent, (2) the individual of moderate means and (3) those who can properly finance their medical care.

Various clinics and other institutions supplying medical care were already operating in Alameda County with little cooperation and no coordinating body. In 1917 the county board of supervisors established the Alameda County Institutions Commission for the purpose of taking entire charge of all county institutions wholly supported by county funds and designed for the care of the indigent sick.

In 1930, when the problems of medical care became more acute, another survey was made. The report of this survey recommended that all indigents be referred to clinics operated by the County Institutions Commission, or to county physicians who were regular salaried employees on a part time basis. All pay clinics were abolished.

These changes left in the hands of the Alameda County Medical Association the problem of caring for the low income group, who in the new arrangement were left without medical care. After an extensive investigation, the association adopted the following resolution in October 1932:

*Resolved* That it appears to be necessary to establish a plan whereby certain patients formerly cared for at health centers who do not technically fall under the term 'indigent' and at the same time require attention at the hands of reputable physicians and whose care should be assumed at a fair price within the ability of the patient to pay and be it further

*Resolved* That the Alameda County Medical Association agrees to establish a list of physicians who will volunteer to accept calls for such classes of patients and to render service when called in cooperation with the established official county agencies and centralized social service as established in Alameda County and according to such additional plans as may be adopted.

The call for volunteers to cooperate in carrying out the plan met with practically 100 per cent response from the members of the association.

Arrangements were then made for a cooperative plan by the medical association and the County Institutions Commission.

<sup>3</sup> Osler, William. Visceral Manifestations of the Erythema Group of Skin Diseases. Am. J. M. Sc. 127, 16, 1905.

<sup>4</sup> Ward, S. B. Erythema and Urticaria with a Condition Resembling Angioneurotic Oedema Caused Only by Exposure to the Sun's Rays. New York M. J. 81, 742, 1905.

<sup>5</sup> Bazin. Hydroa vacciniforme. Cours de semiotique cutanee. 1855.

<sup>6</sup> Hutchinson, J. Summer Eruption. Clinical Society's Transactions 22, 1888.

<sup>7</sup> White, J. C. Hydroa Vacciniforme. J. Cutan. Dis. 1898, p. 514.

<sup>8</sup> Cold Allergy and Drowning. editorial. J. A. M. A. 101, 1644 (Nov. 18), 1933.

Members of the medical association agreed to treat nonindigent patients privately for whatever fee they were able to pay, provided their ability to pay could be determined by the County Medical Social Service, and provided any necessary social work could be rendered by medical social workers of the clinics.

"The Social Service Department of the County Institutions Commission is responsible for contributing the following types of assistance to physicians participating in the Plan:

(a) Social study (economic situation, home and work environment habits and attitudes of patients and family which may have a bearing upon the medical problem).

(b) Medical Social Case Work (aiding the patient or his family to meet social problems related to his illness and mobilizing the resources of the community to make possible the carrying out of medical treatment).

(c) Determination of the patient's ability to pay for medical care. The Social Worker's chief contributions here are:

(1) Securing adequate data regarding financial status of patient and family.

(2) Evaluating this in terms of the social and medical need of the patient.

(3) Assisting patient and family to develop an attitude of willingness to pay for medical care and aiding them to develop resources for payment within their means.

(4) Securing relevant information from other agencies who have known the patients.

Recommendations as to fees patients can pay naturally become a by-product of the above investigation.

The Medical Worker has the following relationship to any business agency established for the purpose of credit rating:

(a) She can give a professional opinion as to the patient's financial resources, and his attitude of cooperation with the physician.

(b) She cannot take the place of the credit agency in investigation of the patient's past records as to credit rating and the risks involved in extending credit to him."

When a call for service is made at any of the county institutions, the social service department ascertains whether the patient is already receiving relief and, if so, or if known to be indigent the patient is referred to county physicians.

If the patient's financial status is unknown or if he is known to be able to pay something for a home visit, the worker explains that a private physician will be sent and that the physician will discuss with him the matter of payment.

The worker then refers the call by telephone to the next physician on the rotating list, giving him the data for Section A and B of Form 2538. She stamps the date on the physician's card and places the card at the end of the list. She records this call on the 'Report of Patients Referred to Private Physicians'. In case the first physician called cannot go, she continues down the list until she finds a physician who can make the call.

The physician makes at least one visit and renders the necessary service regardless of the patient's ability to pay any part of his fee. He then fills out a form giving certain social information and sends this to the social service department, which notifies the local clinic if a social investigator is requested by the physician.

Part-pay patients are referred to private physicians only after their financial status is known, and in accordance with the following procedure:

1 The social worker who has investigated the patient secures the name of the next physician on the list from the worker in that agency who keeps the list. The latter is responsible for stamping the date on the physician's card and records the referral on the Report of Patients Referred to Private Physicians.

2 The social worker discusses with the patient the matter of payment and an understanding of the amount to be paid is arrived at before the case is referred to the private physician. The patient is also told that he will be expected to pay cash.

3 The social worker secures from the patient the signed consent for transfer of information and files this with the social case sheet.

4 She communicates with the private physician and arranges an appointment for the patient.

5 The patient is given a Refer Slip signed by the worker, on which is recorded the name and address of the physician and the date and hour of the appointment.

6 The social worker is responsible for sending to the physician any medical or social data contained in the clinic records which might be helpful to him in treating the patient.

7 The case is then closed at the clinic for that complaint and considered a private patient until such time as the physician may refer it

back or until some other medical condition arises for which the patient cannot afford private care.

It is understood that the physician may request and receive assistance from the clinic social worker at any time.

Full pay patients are referred to the Secretary of the Alameda County Medical Association, for names of physicians from her own list.

During the year 1933, 2,077 referrals to private physicians were made by social workers, clerks, nurses, doctors and others in the Alameda County agencies. These referrals were made to the three groups of physicians listed in table 1 (a) those who were members of the Alameda County Medical Association and had agreed to take patients at reduced fees, (b) those who were not members of the Alameda County Medical Association and whose names therefore, were not on the list, (c) referrals made to the secretary of the Alameda County Medical Association with the understanding that the patients could pay a full fee.

TABLE 1—Distribution of Referrals for Medical Services Under the Alameda County Plan, Made to Physicians in the County in 1933

	Number Per Cent	
Total Referrals	2 077	100 0
To County Medical Association	1 898	91 3
	Number Per Cent	
To Co Med Asso	1 898	100
For Part pay care	1 812	95
For Full pay care	56	5
To Physicians not on list	158	6 5
To Physicians names not given	51	2 2

Of the total number of referrals made, 1,898, or 91 3 per cent were made to physicians of the Alameda County Medical Association, only 158, or 6 5 per cent, were made to physicians not on the list, the remaining 22 per cent of the referrals were to physicians whose names were not stated but who might possibly have been members of the Association.

Of the 1,898 referred to the medical association, 95 per cent, or 1,812 referrals, were for part-pay medical care, and 5 per cent, or 56 referrals, were for full-pay medical care.

The following study has been made of the results of the first year's referrals.

Questionnaires were sent, March 1, 1934, to the 400 physicians whose names were on the part-pay lists and who were members of the Alameda County Medical Association. Information was requested on only the 1,812 cases referred for part-pay care.

Returns were received from 279 doctors, or 70 per cent of the number to whom questionnaires were sent. These returns gave information about 1 304 referrals, or 71 96 per cent of the referrals about whom information was desired.

TABLE 2—Patients Actually Seen

	Number Per Cent	
Total number about whom information has been received	1 304	100
Patients seen by doctor	969	74 3
Patients not seen	335	25 7

The table shows that, of the 1,304 patients about whom some information was received, 969, or 74 3 per cent, were actually seen by various physicians, and 335, or 25 7 per cent, were not seen by the doctors to whom they had been referred.

Of the 969 patients seen, table 3 shows the percentage and the number of patients who paid no fees.

TABLE 3—Number of Patients Paying Fees

	Number Per Cent	
Total number of patients seen	969	100
Patients pay fees	736	76
Patients paying nothing in fees	233	24

It can be seen from this table that 76 per cent of the patients actually seen paid something for their medical services, while only 24 per cent paid nothing. A complete study of the amounts received from these 736 patients has not yet been made, but the total is slightly over \$5 000.

## Association News

### MEDICAL BROADCASTS

#### Columbia Broadcasting System

The American Medical Association broadcasts on a Western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4 30 to 4 45, central standard time. The next three broadcasts will be as follows:

October 4	Autumn Leaves	W W Bauer	M D
October 11	Multiple Births	W W Bauer	M D
October 18	Keep Fighting Diphtheria	W W Bauer,	M D

#### National Broadcasting Company

The American Medical Association broadcasts on a Blue network of the National Broadcasting Company each Tuesday afternoon from 4 to 4 15, central standard time. The next three broadcasts will be as follows:

October 2	Curiosities of Medicine	Morris Fishbein	M D
October 9	School Health Problems	W W Bauer	M D
October 16	Research in Medicine	A C Ivy	M D

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

### ARKANSAS

**Society News**—At a meeting of the Sixth Council District Medical Society in Hope, September 11, speakers were Drs Philip M McNeill, Oklahoma City, on complications and treatment of pneumonia, Davis W Goldstein, Fort Smith, common skin diseases, Willis C Campbell, Memphis, osteomyelitis, Millington Smith and Joseph W Kelso, Oklahoma City, cancer of the cervix and Samuel E Thompson, Kerrville, Texas, diagnostic problems in diseases of the lungs. The Mississippi County Medical Society was addressed at Blytheville August 7, by Drs Lorenzo D Massey, Osceola, on 'Use of Sodium Thiocyanate in Dysentery', Percy H Wood, Memphis, Tenn, 'Practical Points in Gynecological Treatment', and Thomas D Moore, Memphis Tenn. The Obstructing Prostate.—Speakers before the Tri-County Clinical Society in Arkadelphia, July 26 included Drs Solomon F Hoge on early syphilis, Paul L Mahoney differential diagnosis between otitis media and external ear infection, Francis W Carruthers, fractures, and J O Hall, DDS, oral health. All were from Little Rock.

### ILLINOIS

**Encephalitis Decreases**—That epidemic encephalitis is on the wane in Illinois is indicated in reports of twenty-four new cases of the disease for the week beginning September 10. This number compares with a total of forty-nine for the preceding week. The Illinois State Department of Health reports that the bulk of the cases continue to occur in the three main epidemic centers: Vermilion County, eight, Fulton County, four, and Peoria County, three.

**Society News**—At a meeting of the Peoria City Medical Society, September 18, Dr Max Thorek, Chicago, discussed a new method of obliterating the gallbladder by electro-surgical means.—The St Clair County Medical Society was addressed in Belleville, September 5, by Dr Edmund Bechtold on "Economic Conditions as I Found Them in the Scandinavian Countries and in Russia" and by Dr Frederick V Emmert, St Louis, in East St Louis September 6, on "Diagnosis and Treatment of Cervicis in Office Practice."

#### Chicago

**Founders' Day at Northwestern**—Ceremonies on Tuesday, October 2 will mark the opening of the seventy-sixth annual session of Northwestern University School of Medicine. The Founders' Day address will be delivered by Leshe B Arey, PhD Robert L Rea professor of anatomy, on "Old Ideals in Modern Medicine." A feature of the celebration will be the unveiling of an oil portrait of Dr William E Morgan, emeritus professor of surgery and clinical surgery, Loyola Uni-

999

University School of Medicine, and a graduate of Northwestern class of 1882. The portrait, presented by Dr Charles F Sawyer, clinical professor of surgery at Loyola, will be placed in the Archibald Church Library. Dr Sawyer graduated from Northwestern in 1904.

**Dr Bachmeyer Succeeds Dr Houghton at University Clinics**—Dr Henry S Houghton, who since January 1 has been associate dean of the Division of Biological Sciences and director of the University Clinics, University of Chicago, has resigned to become advisory representative of the China Medical Board, effective January 1. The new director of clinics is Dr Arthur C Bachmeyer, who until his resignation, September 15, had been dean of the University of Cincinnati College of Medicine, Cincinnati, for nine years. Dr Bachmeyer, following his resignation as dean, continued as superintendent of the Cincinnati General Hospital and as professor of hospital administration. He has been head of the hospital for twenty years. Dr Houghton, until his affiliation with the University of Chicago, had been dean of the University of Iowa College of Medicine since 1928. The China Medical Board, an agency of the Rockefeller Foundation, owns and supports the Peiping Union Medical College.

centers in the eastern section of the state and the surgical course in three centers in the central part. Two hours one evening each week will be devoted to the courses, which will run for ten weeks. The fee for each is \$10.

## MAINE

**Clinical Meeting**—Dr Timothy Leary, Boston, will be the speaker at the dinner of the Maine Medical Association during its clinical session, October 4, at the Eastland Hotel in Portland. His subject will be "Coronary Sclerosis—A Metabolic Disease, with Analogies to Diabetes, Gout and Obesity." The Cumberland County Medical Society will be host at the dinner. Previous to this, a reception will be held at the home of Dr Edville G Abbott, Portland for members of the state association. No formal papers will be presented at the dinner session. The program to be devoted to clinical demonstrations in medicine and surgery.

## MASSACHUSETTS

**Society News**—The Plymouth District Medical Society was addressed in July, among others, by Drs Arrial W George on x-ray diagnosis of fractures, John D Adams, back sprains, Herbert H Howard, prostate and backaches, Charles A Knowles, rupture of the spleen, and Cadis Phipps, diagnosis and treatment of vascular diseases. Dr Francis T Hunter, Boston, spoke on hematology before the Worcester District Medical Society in Worcester, September 12.

## MICHIGAN

**State Medical Election**—Dr Grover C Penberthy, Detroit was chosen president-elect of the Michigan State Medical Society at its annual meeting in Battle Creek, September 11-13. Dr Richard R Smith, Grand Rapids, was inducted into the presidency. At this session, the house of delegates decided to defer action on its "Mutual Health Service Plan." A few days before the meeting, the committee on medical economics released its report on "Post Graduate Medical Education and the Needs of the General Practitioner," a brochure of sixty-four pages, an attempt to consider the subject in a comprehensive form.

**Centers of Graduate Study**—The establishment of three additional teaching centers has been announced by the department of postgraduate study, University Hospital, Ann Arbor. In these centers, Flint, Grand Rapids and jointly in Battle Creek and Kalamazoo, a course of instruction will begin the first week of October to continue for eleven weeks. Five hours one day each week will be devoted to the course. Intended especially for the general practitioner, the program is identical for each center, consisting of case demonstrations and bedside clinics in traumatic and emergency surgery, fractures, cardiology, metabolic diseases, gynecology and obstetrics, pulmonary disease, gastro-enterology and pediatrics.

## MINNESOTA

**Midwife Also Practices Medicine**—Mrs Regma Krzan Dlugi, a licensed midwife who lives on a farm near Little Falls, was recently warned to stop practicing medicine without a license, following an investigation by the state board of medical examiners. Mrs Dlugi had been selling roots and herbs and medicines.

**Hobby Exhibit**—Members of the Olmsted-Fillmore-Houston-Dodge County Medical Society held a "hobby show" at the Rochester Country Club in July, consisting of an exhibit of etchings, paintings, unusual photography, wood carving sculpture, coins, pottery and guns. Included among those participating were:

- Dr Porter P Vinson hobby of gardening depicted by a figure of a man made up from a dark shirt with garden instruments
- Dr Laurence F V Sutton Mazeppa a 200 year old Belgian print
- Dr Charles G Sutherland notebook containing records of stories heard
- Dr Duncan M Masson and Arthur H Sanford Leica photographs
- Dr John E Crewe paintings
- Dr Frederick A Willius pen and ink sketches of old streets quaint architecture home scenes and bridges
- Dr Albert A Snell old coins from Europe Asia and the United States
- Dr Monte C Piper pioneer relics namely an old millstone a gram shovel and a solid handmade walnut mold used for casting metal wheels
- Dr Louis B Wilson old firearms from Italy Austria Germany
- Dr Walter H Judd Chinese embroidery and clothing

**Society News**—Dr Lewis S Jordan, Granite Falls, superintendent of the Riverside Sanatorium, was elected president of the Minnesota State Sanatorium Association at the recent annual meeting in Cannon Falls. Dr George I Badeau

## INDIANA

**Cancer Program**—Dr Marcus W Lyon Jr, South Bend, will open the meeting of the St Joseph County Medical Society, October 2, with a paper on "History and Etiology of Cancer." This is the first paper in a series to be given in a cancer education program sponsored by the society, newspapers reported.

**Indiana in Morbidity Reporting Area**—Indiana was recently made a part of the U S Public Health Service morbidity reporting area, according to the state medical journal for September. Only those states that have a complete and reliable record of communicable diseases are included in this reporting area.

**Deaths from Encephalitis Increase**—Twenty-one cases of encephalitis with eleven deaths were reported in the outbreak in Evansville up to September 19, according to the Chicago Tribune. One death and twenty-nine cases of the disease had been reported for Washington and vicinity, September 19. Earlier reports stated that seventy cases had been treated in Hartford City.

**Lilly Research Laboratories to Be Dedicated**—The formal opening of new headquarters for the Lilly Research Laboratories, Indianapolis, will take place October 11. The program will open with an informal luncheon at the laboratories which will begin at 2 o'clock. This program will include as speakers Mr J K Lilly, on "Research in Manufacturing Pharmacy," Irving Langmuir, Ph D, Schenectady, N Y, "Unpredictable Results of Research," Sir Frederick Banting, Toronto, "The Early Story of Insulin," and Sir Henry Dale, London, "Chemical Ideas in Medicine and Biology." At a formal dinner in the evening at the Indianapolis Athletic Club the speakers will be Sir Henry Dale, Dr George H Whipple, Dr Charles R Mott, Boston, Frank R Elliott, Ph D, Chicago, Dr Charles R Stockard, New York, Dr George H Whipple, Rochester, N Y, Carl Voegtlin, Ph D, Washington, D C, and George H A Clowes, Ph D, Indianapolis.

## IOWA

**Secretary Honored**—Dr Harry W Vinson Ottumwa for many years secretary of the Wapello County Medical Society was guest of honor at a dinner, September 5. He was presented with a desk set by Dr Smith A Spilman, Ottumwa on behalf of the society, and an album containing the signatures of all those who attended the meeting, by Dr William C Newell, Ottumwa.

**Outbreak of Malaria**—Newspapers announced an epidemic of malaria in and about Booneville. September 6, nineteen cases having been reported in a CCC camp. Inspection showed larvae of mosquitoes in the drainage system, which was connected with two other sewerage systems from Booneville. A drive to clean up breeding places of mosquitoes was begun as the result of the outbreak.

**Graduate Courses**—Diagnosis and treatment in internal medicine and surgery will be the principal subjects of consideration in two courses to be given by the speakers' bureau of the Iowa State Medical Society this fall. Members of the faculty of the State University of Iowa College of Medicine will present the courses which this year will be run separately in three different centers instead of together as has been done in the past. The medical course is to be offered in three

Brainerd, was elected president of the Northern Minnesota Medical Association at its annual meeting in Brainerd September 10-11, Dr Arthur N Collins, Duluth, vice president and Dr Oscar O Larsen, Detroit Lakes, secretary. The next annual meeting will be held in Duluth.

## NEW YORK

**Hospital News**—Dr Louis Faugeres Bishop Jr, New York, began a series of lectures on electrocardiography, August 14, at John T Mather Memorial Hospital, Port Jefferson.—Drs Henry G Hollenberg Cincinnati, and Luther W T Oehlbeck, Rochester, have recently been appointed to the staff of Clifton Springs Sanitarium and Clinic, Clifton Springs.

**Society News**—Charles W Ballard, PhD, New York, addressed the Westchester County Medical Society, September 18, at Grasslands Hospital, Valhalla, on "Prescriptions and the Pharmacopeia"—Medical record librarians of twelve hospitals in Westchester County have organized the Association of Medical Record Librarians of Westchester County, with Edith T Fields of Grasslands Hospital, Valhalla as president and Martha Davidson, Mount Vernon Hospital Mount Vernon as secretary.—The New York State Association of Public Health Laboratories will hold its midyear meeting at the state laboratory in Albany, November 2.

## New York City

**Personal**—Dr Bruno Gebhardt, director of the German Museum of Hygiene, Munich, was guest of honor at a luncheon given by public health officials, August 24, he attended the meeting of the American Public Health Association in Pasadena.—Dr John E Jennings Brooklyn, has been appointed a member of the New York City Board of Health.

**Examination of Food Handlers Discontinued**—Through an amendment to the sanitary code adopted September 18, the New York City Department of Health has abolished the yearly examination of food handlers except for those engaged in the milk industry. Dr John L Rice, city health commissioner emphasized in a statement that hereafter greater attention would be given to the personal hygiene of food handlers and to the entire matter of food sanitation. The action, reversing a policy adopted eighteen years ago, was based on two objections. First it was said that a clean bill of health given to a food handler may have no significance a week later. A second objection arises from the fact that the presence of certain infectious conditions can be determined only by repeated painstaking examinations, which are practically impossible; the cost would be very great and the benefits to the public small. Dr Rice declared in that hundreds of thousands of dollars would be spent to discover at most only a few potential spreaders of disease. It is also pointed out that the health department has more effective measures available for dealing with the possible spread of infection by food handlers. Over reliance on the physical examination of food handlers has brought with it a diminishing emphasis on personal hygiene and matters of general sanitation, Dr Rice continued. It is proposed now to lay more emphasis on the simple matter of frequent hand washing and on sterilization of eating and drinking utensils. The commissioner stated that during 1933 the department had issued 361,289 cards to food handlers, the activity taking up the full time of a considerable number of clerks as well as the time of a physician supervisor. To keep the cards on which the results of the examinations are recorded filing cabinets and valuable space are required. Altogether the commissioner feels that this is an unprofitable procedure for the records, he says, have little value. Judged by the criterion of reducing disease and death, the cost of the health examination of food handlers is enormously out of proportion to the returns yielded to the people of the city.

## OHIO

**Year Book Available**—The Hundred Year Book of the College of Medicine, Ohio State University will be ready for delivery during the annual meeting of the Ohio State Medical Association October 4-6. It contains a complete history of the medical school from 1834 to 1934, including the report of the hundredth anniversary celebration and the addresses made on that occasion. Subscriptions to the book are \$10, and checks may be made payable to A J Linn secretary to the dean of the college of medicine, Columbus.

**Diphtheria Campaign in Toledo**—The Toledo Academy of Medicine announces a campaign for the immunization of all Toledo children against diphtheria, to be carried on from October 7 to November 7 in cooperation with the city health department and various organizations. It is planned that pri-

vate physicians shall do the work for children of their own patients and that the children of indigents will be taken care of through relief funds. Dr Walter W Beck is chairman of the committee in charge of the campaign.

**District Society Meeting**—The Northwestern Ohio Medical Association will hold its ninetieth session in Toledo, October 2, at the headquarters of the Toledo Academy of Medicine. Guest speakers will be:

Dr Douglas Quick New York Diagnosis of Malignancy Treatment of Malignancy  
Dr Frederic Maurice McPhedran, Philadelphia Diagnosis of Tuberculosis in Infancy and in Grade School Age Diagnosis of Tuberculosis in Adolescence and Adult Life  
Dr Raphael Isaacs Ann Arbor Mich Newer Developments in Diagnosis and Treatment of Diseases of the Blood Forming Organs  
Dr Milton B Cohen Cleveland Principles and Practices in the Management of Patients with Allergy  
Dr Alvin R Morrow Chicago Head Injuries

**Society News**—Dr Frank C Huth, Cambridge, addressed the Guernsey County Medical Society, August 16, on mammary tumors.—Dr Claud R G Forrester, Chicago, addressed the Summit County Medical Society in Akron, September 4, on "Reduction of Acute Fractures Under Local Anesthesia Together with Ambulatory After-Care"—Dr Hugh Cabot, Rochester, Minn, addressed the Academy of Medicine of Cleveland, September 21, on "New Conceptions of the Diagnosis and Treatment of Urinary Tract Infections"—Dr Carl J Wiggers, professor of physiology, Western Reserve University School of Medicine, Cleveland, gave a series of lectures on recent advances in applied physiology before the Mahoning County Medical Society, Youngstown, during the past month.—Drs Grover C Penberthy and William H Gordon, Detroit, addressed the Hancock County Medical Society, Findlay, September 6 on surgical management of burns and treatment of diabetes during pregnancy, respectively.

## RHODE ISLAND

**Society News**—At the quarterly meeting of the Providence Medical Association, September 6, speakers were Drs George A Elliott, Middletown, Conn, on "Paraldehyde and Other Hypnotics Recent Developments", Arthur H Ruggles, Providence "Function of a Hospital for Children with Nervous Diseases," and Charles Bradley, East Providence, "Nervous and Mental Problems of Childhood"—Dr Ellen A Stone, Providence, has retired after twenty-one years as superintendent of child hygiene in the city health department.

## TENNESSEE

**Health at Memphis**—Telegraphic reports to the U S Department of Commerce from eighty-six cities with a total population of 37 million for the week ended September 15 indicate that the highest mortality rate (17.1) appears for Memphis, and that the rate for the group of cities as a whole was 9.9. The mortality rate for Memphis for the corresponding week of 1933 was 15.7 and the group of cities 9.5. The annual rate for the thirty-seven weeks of 1934 was 11.5, as compared with 11 for the corresponding period of last year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have large Negro populations may tend to increase the death rate.

**Society News**—Drs William C Chaney and John L Jelks Memphis, addressed the Tri-County Medical Society (Carroll, Henry and Weakley counties) at McKenzie, August 14, on "Practical Considerations of Gastro-Intestinal Allergy" and "Rectocolonic Diseases" respectively.—Speakers at a meeting of the Roane McMinn Monroe, Blount and Loudon Counties Medical Society at Kingston August 22, were Drs John B Youmans, Nashville on "Noninstrumental Diagnosis of Common Cardiac Arrhythmias", James E Carson, Maryville, "Perihepatic Abscess," and William J Cameron, Sweetwater "Treatment of Endocervicitis by Electrocoagulation"—At a meeting of the Nashville Academy of Medicine, September 4 Dr James Frazier Binns discussed "The Management of Diarrhea of Infancy."

## TEXAS

**Bill Introduced**—H 55-XXX proposes to forbid the sale of barbituric acid derivatives and compounds thereof under any copyrighted or chemical name, except on the prescription of a licensed physician. The proposed act however, is not to affect the sale of such drugs by wholesale drug houses to retail pharmacies or to physicians. A licensed physician is free to dispense these drugs but apparently, will be able to buy them from retail pharmacies only on prescription.

## VERMONT

**State Medical Meeting at Burlington**—The one hundred and twenty first annual meeting of the Vermont State Medical Society will be held in Burlington, October 4-5, at the Flemming Museum. A symposium on the kidney will be presented by four New York physicians Drs Arthur M Fishberg, Paul W Aschner, Moses Swick and Albert A Epstein. Dr Dean Lewis, Baltimore, will give an address and other guests will be Drs John M Bergland, Baltimore, on "Obstetrical Complications", Henry D Chadwick, Boston "Prolongation of Life", Winchell McK Crug, Rochester, Minn "Physiology, Pathology and Treatment of Craniocerebral Injuries". Vermont physicians on the program are Drs Maurice N Belterose, Rutland "Intervertebral Pressure", Clarence F Ball, Rutland, "Radiation Treatment of Tumors—Late European Developments," and Charles K Johnson, Burlington "Atrophic Fever in Early Infancy". The annual banquet will be at the Ethan Allen Club Thursday evening, October 4.

## WASHINGTON

**Half a Century in Medical Practice**—More than 100 physicians attended a dinner in honor of Dr Lewis R Dawson Seattle, August 13, marking his fiftieth anniversary in medical practice. Dr Dawson was graduated from the University of Michigan Medical School, Ann Arbor, in 1882 and licensed to practice in 1884.

**Society News**—Drs William C Woodward, Chicago, and Walter C Woodward, Seattle, will address the King County Medical Society, Seattle, October 1 on malpractice and malpractice suits. Drs Clyde W Countryman Spokane and James E Hunter, Seattle, addressed the society, September 17, on "The Postoperative Enema" and "Functional Disorders of the Colon," respectively.

## WISCONSIN

**State Medical Election**—Dr Ralph M Carter Green Bay, was chosen president-elect of the State Medical Society of Wisconsin and Dr Thomas J O'Leary, Superior was installed as president at the annual session in Green Bay, September 10-13. Dr Gunnar Gundersen, La Crosse was elected speaker of the house of delegates to succeed Dr Carter. The 1935 convention will be held in Milwaukee.

## GENERAL

**Changes in Status of Licensure**—The following action was taken at the meeting of the Florida State Board of Medical Examiners in Jacksonville, June 12:

Paul C Ronning, Lake Worth license revoked on the ground that he had been fraudulently obtained.

**Shoe Companies Stop Using the Title "Dr."**—Six shoe companies in New York and New England have signed agreements to discontinue misrepresentation in the sale of shoes, the Federal Trade Commission has announced. Complaints against the companies charged that all used the word "doctor" or abbreviation "Dr" in such manner as to lead buyers to believe the shoes were designed under a physician's supervision and contained special orthopedic features, the report stated.

**News of Epidemics**—Eighteen cases of malaria occurred in Aurora Portage County, Ohio, in the two weeks preceding September 8.—Opening of schools in Spokane, Wash., was delayed indefinitely in an order issued by the city health officer, August 30 because of the prevalence of poliomyelitis. A report of the state health department stated that eighty-five cases had occurred in the state in July and fifty-seven during the first two weeks in August.—Fifty-seven cases of poliomyelitis were reported in Montana during the week ended September 1, 179 cases have occurred in the state since June, centered principally in Helena, Billings and Great Falls.

**Bequests and Donations**—The following bequests and donations have been announced:

Lenox Hill Hospital \$33,333. St Vincent's Hospital \$25,000. New York Foundling Hospital \$25,000. Home for Incurables \$25,000. Presbyterian Hospital \$20,000 for cancer research. Seton Hospital \$15,000 by the will of the late Mrs Madeline L. Ottman. Jewish Hospital Brooklyn \$2,000 by the will of the late Gittle Kurtz. St Catherine's and Bethany Deaconess hospitals New York \$1,000 each by the will of the late Amelia A. Scheidt. The Tuberculosis Preventorium Farmingdale N. Y. \$1,000 by the will of Marcus M. Marks. Hospital for Joint Diseases New York \$15,000. New York Academy of Medicine \$10,000. American College of Surgeons \$1,000. Gorgas Memorial Institute \$1,000 and New York Physicians Mutual Aid Association \$1,000 by the will of Mrs Perla A. Brickman. St Vincent's Hospital New York \$1,050 by the will of Elizabeth Thompson. Huntington Hospital Huntington L. I. \$5,000 by the will of the late Miss Abbie E. Jones. White Plains Hospital Association White Plains N. Y. \$1,000 by the will of the late Ambrose F. McCabe.

**Society News**—Dr John H. Hale, Nashville, Tenn., was elected president of the National Medical Association at its recent annual meeting in Nashville, the next annual meeting will be held in New Orleans in 1935.—Officers elected at the recent annual meeting of the Thirteenth Annual Convention of the International Association of Police and Fire Surgeons in Philadelphia were Drs Harry M. Archer, New York, president, George L. Wright, Syracuse N. Y., vice president, and Arthur Wildman, Brooklyn, secretary.—Dr John S. Hibben Pasadena, Calif., was chosen president-elect of the American Congress of Physical Therapy at the annual meeting in Philadelphia recently. Dr William L. Clark, Philadelphia was installed as president and the following were elected vice presidents: Drs William Bierman, New York, Frederick L. Wahrer, Marshalltown, Iowa, Walter P. Grimes, Kansas City, and Frank H. Krusen, Philadelphia. The gold key of merit of the congress was awarded to Dr Leroy W. Hubbard, Mount Vernon, N. Y., William W. Coblenz, Phila., Washington, D. C., Henri Bordier Lyons, France, Oscar Bernhard, St. Moritz, Switzerland, and Franz Nagelschmidt, formerly of Germany, now of London.—Dr Walter H. Brown, Palo Alto, Calif., was chosen president-elect of the American Public Health Association at the annual meeting in Pasadena, September 4-7. Dr Eugene L. Bishop, Nashville, became president.—The thirteenth annual congress of anesthesiologists will be held in Boston, October 15-19. Societies that make up the congress are the Associated Anesthetists of the United States and Canada, the International Anesthesia Research Society, Eastern Society of Anesthetists and the Mid-Western Association of Anesthetists.

## HAWAII

**Aloha Picnic**—The Honolulu County Medical Society held an "Aloha picnic" at Lanikai, Oahu, September 9, in honor of Col Ernest L. Ruffner. The picnic was preceded by a golf tournament. Colonel Ruffner has been department surgeon of the Hawaiian Department of the U. S. Army for several years.

**Graduate Lectures**—Dr David P. Barr, Busch professor of medicine, Washington University School of Medicine, St. Louis, gave three lectures before the Honolulu County Medical Society, September 12-14 under the auspices of the committee on postgraduate instruction. His lectures were entitled "The Pituitary Gland," "Hypoglycemia and Related Conditions" and "Parathyroid Gland and Calcium Metabolism."

## CANADA

**Institute of Parasitology**—The official opening of the new Institute of Parasitology at Macdonald College, McGill University, Montreal, took place June 27. The government of Quebec provided the building and the National Research Council has undertaken the maintenance. Henry M. Tory, LL.D., president of the National Research Council, made the official address at the opening ceremony and Thomas Wright Moir Cameron, Ph.D., director of the institute, accepted the keys. A part of the building has been in operation for about eighteen months (THE JOURNAL, Aug 27, 1932, p. 771).

**Endowment for Department of Neurology**—Science reports that the Rockefeller Foundation has appropriated \$1,000,000 to McGill University, Montreal, as an endowment for the department of neurology. This fund is to take the place of \$50,000 contributed annually to carry on work in neurology under the direction of Dr Wilder G. Penfield. The foundation has previously contributed \$232,000 toward the erection and equipment of a building for the department (THE JOURNAL, June 18, 1932, p. 2220). The province of Quebec also makes an annual grant of \$20,000 and the city of Montreal, \$15,000 to the institute.

## FOREIGN

**Prize for Encephalitis Research**—The University of Bern, Switzerland, announces that a prize of 1,000 francs will be awarded for research on epidemic (lethargic) encephalitis through a foundation recently established. Information may be obtained from the dean of the medical faculty of the university.

**Personal**—Dr Samuel James Cameron has been appointed regius professor of midwifery at the University of Glasgow to succeed Prof J. M. Munro Kerr who retires September 30.—Prof George Grey Turner, professor of surgery in the University of Durham, England has been appointed to the chair of surgery in the new British Post-Graduate Medical School at Hammersmith.

**Obstetrics Prize**—A prize of 10,000 Belgian francs is to be awarded every four years by the International Foundation of Gynecology and Obstetrics, originated by the International Congress of Gynecology and Obstetrics and the Societe Belge de Gynecologie et d'Obstetrique, the latter being legal managers of the fund. The prize will be given to the author of the best paper in gynecology or obstetrics published in the four years preceding the award. Two copies of the paper, which must be in German, English, Spanish, French or Italian must be sent to the secretary of the Belgian society (Dr. Max Cheval, 16 Alphonse Hottat Street, Brussels, Belgium) twelve months before the date fixed for the award, July 1938.

**International Neurologic Congress in 1935**—Plans for the second International Neurologic Congress, to be held in London July 29-Aug. 2, 1935, have been announced by the committee for the United States, of which Dr. Bernard Sachs, New York, is chairman and Dr. Henry Alsop Riley, New York, secretary. Four topics have been chosen for consideration: the epilepsies, physiology and pathology of the cerebrospinal fluid, functions of the frontal lobe, and the hypothalamus and the cerebral representation of the autonomic system. These subjects will be presented at morning sessions, and afternoon sessions will be devoted to discussion of miscellaneous topics. Any recognized neurologist or psychiatrist may submit titles for presentation at the miscellaneous sessions. Such titles, accompanied by brief abstracts, must be submitted to the United States committee before Jan. 15, 1935, in English, French or German. Those accepted will be forwarded to the secretary general in London for final consideration. The maximum time for presentation will be ten minutes. Candidates for membership may apply either through the national committee or through the secretary general of the congress. Dr. S. A. Kinnier Wilson, 14 Harley Street, London. Thomas Cook and Son are official travel agents for the congress, and arrangements for traveling and hotel accommodations may be made through them. Requests for application blanks and the submission of titles should be made as soon as practicable. In addition to Dr. Sachs and Dr. Riley, members of the committee are Drs. Harvey Cushing, New Haven Conn., Charles L. Dana, Woodstock, Vt., Adolf Meyer, Baltimore, and Frederick Tilney, New York. Dr. Riley's address is 117 East Seventy-Second Street, New York.

#### Deaths in Other Countries

Georges Dreyer, professor of pathology, University of Oxford, England, since 1907, died August 17, in Solstedgaard, Laaland, Denmark, of heart disease.

## Government Services

### New Home of Public Health Service

The National Institute of Health of the U. S. Public Health Service is now occupying its new buildings, the transfer from the old structure to the new quarters having taken more than a year. The buildings comprise a two story administration building housing the library and the director's office, and an I-shaped laboratory building, 234 feet long three stories high with a basement. Both are constructed of Indiana limestone and form the western end of the government's building program at Washington. The new laboratory building is entirely occupied by the division of pathology and bacteriology. The old north building will be remodeled for other research activities and the housing of animals while the south building will continue to be occupied by the divisions of pharmacology, chemistry and zoology. (THE JOURNAL, June 17, 1933, p. 1946)

### CORRECTION

"Modern Clinical Syphilology"—The review of "Modern Clinical Syphilology," edition 2, by Dr. John H. Stokes (Philadelphia, W. B. Saunders Company, 1934) published in THE JOURNAL, August 25, page 627, contains the erroneous statement that figure 115 has numerous errors which should be corrected in the next revision. The impression of error arose from a misunderstanding of the captions of certain columns by the reviewer. The figures as given in the table are correct. The reviewer is also in error in stating that lymphogranuloma inguinale was not even mentioned in connection with the anorectal syphiloma. A brief discussion of this relationship occurs on pages 590 and 958.

## Foreign Letters

### Restriction on Use of Automobile Horns

The formation of the Anti-Noise League and other efforts to check noises, which have become such an evil of modern life, have been described in previous letters. An official move in the matter has been made at last. In a broadcast address Mr. Hore-Belisha, minister of transport, announced an innovation for the benefit not only of motorists and pedestrians but also of that section of the population whose point of view has heretofore not been adequately considered—those who live along the roads and whose tranquility is much disturbed by mechanical noises at night. Between the hours of 11:30 p. m. and 7 a. m. the sounding of motor horns will be prohibited in London over a radius of five miles from the central point of Charing Cross. Any motorist who sounds his horn during those hours will be liable to a fine of \$8. After this experiment has been made, other localities will be invited to follow suit. This new silent zone should be a relief to those who find it difficult to get a good night's rest. Will the risks of motor traffic be increased? It is thought not, as the pedestrian before stepping on to the road will be warned by the oncoming lights of the vehicle. As to foggy nights, statistics show that low visibility tends to diminish accidents, because the motorist naturally goes more carefully. To eliminate noise altogether is impossible, but the minister of transport will do all in his power. He has appointed a committee of scientists and motor manufacturers to consider and report on the principal causes of noise in mechanically propelled vehicles and the steps that can be taken to limit them. The government is placing at the disposal of the committee the resources of the National Physical Laboratory. The aim will be to discover the means of making automobiles and motorcycles with as silent a mechanism as possible. It is already an offense to use one that causes any excessive noise. It is equally an offense to sound a horn, even in the daytime, on a stationary vehicle except when necessary on the ground of safety.

This prohibition, which was suggested by the Anti-Noise League a year ago, proved an immediate success. The "zone of silence" contains the principal London hospitals, and the evil of interfering with the night's rest of the patients was used as a strong argument. Many letters approving of the regulation have been received by the ministry. Before it came into force Capt. J. H. Johnson, secretary of the Royal Westminster Hospital, wrote to the ministry asking whether consideration could be given to "the dire necessity" of mitigating to some extent the unpleasant condition with which the patients of his hospital had to contend. He said that the skill of the surgeons was vitiated to a great extent by the disturbance of the patient's rest and that a deleterious effect on the efficiency of the resident staff was also produced. As an experiment he occupied for a night a private room in the hospital. Though in full health and strength, the experience proved a nightmare. A total of 408 vehicles passed in six hours, more than one a minute. These included heavy motor vehicles, such as milk trucks. During his vigil the secretary noticed that forty-four omnibuses stopped outside a neighboring theater and that at least 90 per cent of them hooted vigorously.

The success of the prohibition in London has been so great that after a delay of only a few days, the minister of transport has extended the regulation forbidding the sounding of horns or other instruments of warning to all roads in Great Britain in built-up areas—that is to say, all roads on which there is provided a system of street lighting by lamps placed

not more than 200 yards apart. But the order does not apply to vehicles used for fire department, ambulance or police purposes. It is noteworthy that this silencing by night of the warning noises of automobiles has not led to any increase of accidents.

#### The Taxation of Surgical Instruments

Since England has adopted protection, all the business interests have been coming forward, one by one, demanding a tax on the articles corresponding to those they produce which come from abroad. Everything used from the cradle to the coffin will soon be taxed, even articles used in medicine and surgery. It has been explained how a tax imposed on imported insulin for unfortunate persons with diabetes proved too much for the protectionist government. But a tax on surgical instruments will fall, at first at any rate only on surgeons. The Import Duties Advisory Committee reports that foreign competition is particularly severe in the more commonly used instruments, which may be regarded as standard lines. It says that "a healthy surgical industry" in this country is desirable in the interest of progress in surgery, and that this depends on the retention by British manufacturers of a substantial proportion of the home market in the standard lines as well as in specialized types. The committee has recommended a tax of 20 per cent.

#### The Danger of Using Gasoline for Cleaning Garments

In spite of the fatalities that occur from time to time in the use of gasoline for cleaning fabrics, the danger is not sufficiently appreciated. An inquest has been held in London on two women, aged 36 and 44, who lost their lives in an explosion that occurred while they were cleaning clothing with gasoline. They were doing this in a small area outside a kitchen in which there was a lighted boiler. A double explosion occurred. The husband of one of the women said that he thought the explosion was caused by rubbing. Certain fabrics would ignite by friction. He had known a death caused by a man washing his hands in aviation spirit. An inspector of the London County Council gave evidence. He said that a large amount of gasoline vapor would be released in the cleaning process. There was a space of about a quarter of an inch under the kitchen door and the vapor would flow into the kitchen, where the heat of the stove would set it alight. The coroner said that, if gasoline was used for cleaning, this should be done outdoors and not in the confined space of an area. Though the danger of ignition by friction was mentioned in the evidence, one way in which it has been suggested that this may occur—by the generation of electric sparks—was not referred to.

#### The Danger of Anthrax from Foreign Shaving Brushes

In the admiralty orders to the fleet, a warning is given against the use of foreign shaving brushes. It is stated that a case of anthrax has recently occurred which is believed to have resulted from the use of a shaving brush purchased on shore, and personnel are warned that the fact that a brush is marked "sterilized" is no guaranty that it is free from anthrax infection unless it is of British manufacture. In shaving only service shaving brushes and other sterilized British-made shaving brushes should be used. Foreign brushes should be suspected even if they have been in use for some time, as the anthrax spores may be present in the setting and be released as this becomes softened in use. Therefore such brushes should be destroyed and replaced by British-made ones.

#### The Undiminishing Maternal Mortality

The report of the health officer for the county of Middlesex. Dr. John Tate, shows that the rate of maternal mortality in the county for 1933 rose from 3.85 deaths per thousand births in 1932 to 4.77 for 1933. Women's deaths from causes connected with pregnancy and childbirth numbered 117, an increase

of 19 compared with 1932, although 936 fewer live births took place. The figure 117 was the highest ever recorded for Middlesex. The maternal mortality for the whole country for 1933 was 4.42 per thousand live births, which, though lower than that of Middlesex, was the highest recorded for England and Wales for more than thirty years. Dr. Tate points out that since the beginning of the century maternal mortality rates have shown no diminution and, if anything, have tended to rise. He outlines great reforms that have taken place and says that but for them the maternal mortality would have risen to a considerable height. It seems therefore that these favorable influences must be counterbalanced by some growing adverse factor or factors, possibly connected with the changing habits or mode of living, the nature of which can only be a matter for speculation. The birth rate for the county showed a further sharp fall and was the lowest recorded for any year, not excepting the war years. If the fall continued, the time was not far distant when the population would come to a standstill or even begin to decline.

#### The Problem of Expert Witnesses

For some time many psychiatrists have demanded that in court, when the question of a delinquent's responsibility is raised by the prosecutor, another expert witness be present, in addition to the expert appointed by the court, to represent the interests of the defendant. The results of the practice have been unsatisfactory. The judge, having had no training in psychiatry, delivers his opinion without true discernment when he has to choose between two opposing technical opinions. In a criminal action, when the decision rests with the jury, it is still worse. An expert witness proposed by the attorney for the defense conducts himself in essentially the same manner as the attorney who selects him, and his mission consists in awakening a doubt in the minds of the jurors with regard to the conclusions of the official expert, and in saving the accused from being sentenced. If the accused is rich, he can pay for an expert, possibly a professor of legal medicine, whose influence impresses the judges or the jurors, which latter are commonly persons with little legal experience. The appointment of an expert witness for the defense is not a right that can be demanded. But a large number of psychiatrists want the appointment of an opposing expert witness to be made compulsory and it is not difficult to divine that they envisage the prospect of ample fees, whereas, when they function as official experts, the legal schedule allows them only modest fees.

The question was brought up recently by the Congress of Legal Medicine, at Lille, where it received prolonged consideration. Drs. Raviart and Vullien in their paper emphasized that the penal code does not provide a solution of such delicate problems—responsibility or irresponsibility, prison or psychiatric hospitals. To remedy this state of affairs, it was proposed to permit the appointment of an opposing expert witness to aid in passing on the sanity of the defendant. This innovation, the speakers stated, does not appear to solve the difficulties. The opponents of the reform urge that an expert witness should be above all influence of party considerations. He is the appointee of the court and not of the defense. There should be no confusion between the two issues. His mission is to promote justice impartially. But the expert witness of the defense will always have the set task of bringing up all important facts and all symptoms suitable for casting doubt on the mentality of the accused. The expert witness of the court, mindful of both the interests of the accused and the needs of social defense, and animated by a true medicolegal spirit, will continue, as in the past, to base his conclusions on recognized scientific beliefs. Between the two expert witnesses,

with such widely different points of view, agreement will seldom be possible. An arbiter will be indispensable in a large majority of cases, and as it will often devolve on the judge to choose between the conflicting opinions, there would soon be a lapse back into the present state of affairs. It appears therefore, the speakers stated, that efforts must be directed in another quarter. An entirely different reform must be brought about. A law should be passed similar to one in Belgium, which effects a harmonious accord between charitable ideals and the requirements of social protection. In the discussion that followed this presentation, Charpentier of Paris, Crouzon of the Salpêtrière Hospital, Guillaumet of the Charité-sur-Loire, Dide of Toulouse, Stanesco of Bucharest, and likewise Mc Kah, participated. The congress approved these opinions. 1 The appointment of an opposing expert witness to promote the cause of the defendant is desirable. 2 A larger list of experts should be available. 3 The adoption of a law of social defense patterned after the Belgium law is recommended. These resolutions will be sent to the Society of Legal Medicine, which will hold its congress in Paris at an early date.

#### Laboratory for the Examination of Aviation Pilots

At the Bourget aerodrome, near Paris, a physiologic laboratory called the Pavillon Paul Bert has been established and placed in charge of Dr Garsaux. The new laboratory is provided with modern equipment for research on disorders occurring in pilots as the result of flying, and for the examination of pilots. An enormous caisson in which pilots can be enclosed enables the examiner to study what effects changes in barometric pressure have on them. Other types of apparatus record on charts their emotional reactions, the degree of fatigue, and the like.

#### Dr Auguste Marie

The death of Dr Auguste Marie, at the age of 68 is announced. Dr Marie was an eminent psychiatrist of the contemporary French school. Until his retirement, three years ago, he had been director of the large St Anne Hospital, the most important of its kind in Paris. He was the first physician in France to apply malaria therapy in the treatment of dementia paralytica. In association with Levaditi, he introduced the distinction of neurotropic syphilitic viruses. His published works include research on the doctrines of Freud, sensory perversions, and the nature of artistic productions of mental patients. He organized exhibits of drawings and paintings of patients in the St Anne Hospital and caused thereby no little confusion in the ranks of the art critics. During the war, in spite of his age, he served as physician in a crew of stretcher bearers and suffered a gunshot wound of the cranium. He was the founder of a society for the rendering of aid to mental patients discharged from psychopathic hospitals and a Commander of the Legion of Honor.

#### New Regulations Concerning the Universities

In addition to the changes previously described, further provisions affecting the universities and higher institutions of learning have been enacted. Rust, the federal minister of education, has elaborated plans to secure, at all German universities and higher institutions of learning, a uniform administration, in line with the national-socialist conception of the state, in the prosecution of learning and research, and in the selection of professors. In accordance with this decree, every vacant professorial chair must be reported to him, with an exact description of the nature of the subjects treated, and, after completion of negotiations in connection with the selection of a new occupant, his approval of the appointment must

be secured. Before any scientific institutes can be closed or new ones opened, his consent must be obtained. Also any fundamental changes in the curriculums or in the stipulated forms of examinations must have his endorsement.

R Hess, the representative of the "leader," has issued a decree providing for a special "university commission" of the national-socialist party, in order to bring about a close understanding between the federal administration and the ministries to whose realm the various decrees, appointments and habilitations belong. This commission will investigate all proposals made by the German Hochschulverband or arising from the national-socialist movement and, if approved, will forward them to the proper ministries. The commission will pass on all plans that are developed by the ministries. Hess will be the head of this commission. Alfred Rosenberg, the representative of the "leader" for the supervision of public education, and Dr Wagner, the director of the council on public health, are ex officio members of this commission.

Dr Wagner has the public health service solely in his charge. *Weg und Ziel*, the journal of the national-socialist Aerztebund, has described Wagner's duties in plain terms. "All groups and organizations of the national-socialist party and the public works association, which have to do with the public health, are under the control of Dr Wagner in his capacity of confidential adviser of the representative of the 'leader'." That signifies that in this important field, today the will and the opinions of a single man exert an absolute control. From questions concerning the filling of vacancies in the medical faculties to problems affecting the fee schedules and the organizations of nurses, the decisive national-socialist authority is in the hands of one person—a fact whose significance will not be fully understood until later."

Measures have been adopted to check the flood of new university students (*THE JOURNAL*, March 3, p 710). In the summer of 1934 the number of students showed a decline of 13,884, or 10.4 per cent of the total matriculation of the summer semester of 1932. Of the total number of students at German universities, 97,687 were males and 18,035 were females. This shows a marked decline since the summer semester of 1931. The new matriculations for the summer semester 1931 were males 17,119, females 4,664, or a total of 21,783; for 1932 they were males 15,259, females 3,508, or a total of 18,767, and for 1933 they were males 10,412, females 2,586, or a total of 12,998.

The decline in the number of new students matriculating for the summer semester of 1933 was 5,769, or 30.7 per cent. As the result of an agreement entered into in March 1933 by the various German *lander*, a total of 8,341 graduates (about 19.9 per cent) of secondary schools were advised to forego university study. The percentage of graduates thus dissuaded varies greatly in the several *lander*, the total range lying between 7.47 and 32.23 per cent. The total number of foreign students matriculated for the summer semester of 1933 was 5,484, which denoted a decline of 1,074 (16.38 per cent) as compared with the summer semester of 1932.

There has been considerable talk about the reorganization of the student body. There is to be a general work service plan for the German student body, the chief requirement of which is that it shall bring the need of scientific work into harmony with the storm troop service, the emergency work service, comrade training, demands of the student organizations, the *fachschaftsarbeit* and the work of the national-socialist league. The first attempts to establish a work service for students were fraught with difficulties. An endeavor is being made to create next semester a work service that will take account of the necessities of scientific work. After entering on his duties, the newly appointed leader removed from office (to take effect at once) all the leaders of the German student

body. At the end of August the various local leaders will meet in a *reichsführerlager* (federal camp), where they will receive the new instructions for the work of the next semesters. Such "camps" are now frequently organized. Special camps for medical students have not been provided as yet, although "scientific camps" have been created. In a report on such a camp one reads: "The conception of science in the nineteenth century was based on objective, freedom of speech and independence of thought and action, while the form of organized academic work was protected by the idea of 'academic freedom'." This academic freedom has now been rejected by the German university, and likewise the associated individualistic student type. The conception of political science, the beginnings of which are now recognizable, demands also new forms of academic work and academic instruction, and a new student type. Hence the *wissenschaftslager*, or science camp, is an important working principle of the future German university. Such a camp, for example, may be held for several days in a training school for sport, is characterized by soldierly bearing and a spirit of camaraderie, the language of the camp forbids the use of all forms of address based on academic degrees. Sports and hikes have their place beside mental activities. Each day is spent according to a fixed schedule, planned in advance. For example, in the seminar for political science, carefully directed discussions on the seminar lecture are held, also political talks—for instance, on the state and the intellectual life of the nation. The student who holds himself aloof and does not take part in this community endeavor in which the teacher takes the part of a leader, loses quantitatively the advantages that he hopes to attain by his individual labors, also his scientific conclusions are false. The success of the scientific camp depends on antecedent factors that are not always available as yet. The most important presupposition is a new type of academic teacher, of which there are as yet but few representatives, and they are found chiefly in the younger generation. The scientific camp will be a success only to the extent that it shall prove possible to produce a new type of university instructor.

#### Hereditary Factors in Gynecology and Obstetrics

Before the Berlin Medical Society, Prof. G. A. Wagner pointed out that the literature contains few extensive observations on the significance of hereditary factors in gynecology. The simultaneous appearance of menarche and menopause in different members of a family is frequently observed. One occasionally observes familial disturbances of menstruation affecting large numbers. With respect to myomas, the question of heredity is difficult to decide. Wagner cited instances in which several siblings were subjected to an operation at a relatively early age. Evidence of racial predisposition to myomas has been noted, for instance, in Jewish women. Abnormalities with respect to the endocrine glands are found in certain families. Wagner himself discovered in 1930 the case of two sisters with pseudohermaphroditism.

In obstetrics, disturbances of the birth mechanism, such as weakness due to labor, placenta praevia and placental hemorrhages have not been sufficiently studied to determine their tendency to hereditary manifestations. Much more is known, however, concerning the hereditary nature of rickets. Researches on rachitic twins have established beyond doubt the influence of a hereditary predisposition. The question of sterilization in the presence of a rachitic narrow pelvis should be earnestly considered. A narrow pelvis commonly becomes a grave impediment to birth if there is a marked difference between the size of the father's body and head and that of the mother's for the size of the child's head, which is a decisive factor in the indications for cesarean section, depends, for the most part, on the form of the father's head. Along with chondrodys-

trophia a child often inherits also a chondrodystrophic narrow pelvis. This deformation is no slight matter, although persons with such a deformity are usually rather intelligent (acrobats, clowns and the like). In harmony with Gütt, Rudin and Ruttke, commentators on the sterilization law, sterilization should, after all, be carried out. Chorea gravidarum is subject to hereditary influences, also Osler's disease, or telangiectasia hereditaria. Many family trees point to a distinctly hereditary character of this disease. Deformations due to intra-uterine amputation by amnion strands are doubtless nonexistent in spite of the ancient beliefs of many obstetric assistants to that effect. Such deformations are more likely the result of a pathologic hereditary predisposition. In deciding for or against interruption of pregnancy or sterilization the question of heritability is extremely important and each case must be decided on its own merits so long as knowledge of the subject is so incomplete. Wagner warns against drawing too radical conclusions from existent limited knowledge, for in every sterilization one must be conscious of tremendous responsibility toward the patient and toward society.

#### Experiments on Animals

It will be recalled (*THE JOURNAL*, Feb. 17, p. 551) that the new legislation for the protection of animals contains special provisions concerning scientific experiments. The federal minister of the interior has now announced detailed instructions concerning special permits, issued to scientific laboratories. The semiannual inspections shall be unannounced and shall be made jointly by physicians and veterinarians. Research experiments may be undertaken only if they hold out the prospect of definite scientific gains or serve to clarify unsolved problems. Experiments for purposes of instruction are permitted only when other methods of instruction (pictures, models, specimens, films) are inadequate. During inspections, attention should be given to the equipment used in conducting animal experiments and to the mode of housing the experimental animals. Inquiries must be made in regard to the number of experiments done since the issuance of the permit and concerning the experimental animals employed, with a differentiation of the higher animals (horses, dogs, cats, monkeys) and the lower animals (guinea-pigs, rats, mice, frogs), concerning the duration of the experiments, and as to whether the experiments were performed on anesthetized or unanesthetized animals, whether general or local anesthesia was used, and whether the animals following experiments (during anesthesia or later) were killed in a painless manner. All observed irregularities must be reported at once to the competent ministry, which reserves the privilege of making unannounced inspections. Institutes granted permits must send in regular reports on the scientific animal experiments performed during the previous two years, covering all the details mentioned.

#### BELGIUM

(From Our Regular Correspondent)

Aug. 3, 1934

#### Meeting of International Bureau of Bibliography of Military Medicine

The fourth session of the Office international de documentation de médecine militaire was held at Liege, June 27-30. Twenty-eight governments sent official delegates: Belgium, Brazil, Bulgaria, Belgian Congo, Czechoslovakia, France, Great Britain, Greece, Haiti, Hungary, Italy, Latvia, Lithuania, Luxembourg, Mexico, Monaco, Netherlands, Paraguay, Peru, Poland, Portugal, Rumania, Switzerland, Turkey, the Union of Socialist Soviet Republics, the United States and Uruguay. The delegates from the United States were Lieut. Walter G. Kilbury, Medical Corps, U. S. Navy, and Dr. Hugh de Valin, medical director, U. S. Public Health Service.

Mr Albert Deveze in a stirring discourse pointed out the importance of the medical corps in war. He hoped to see developed, for the benefit of the civil populations, zones of safety in which protection may be given to the wounded and to old men, women and children. He is planning to request the Belgian government to convoke an international conference for the purpose of promoting the movement recently launched at Monaco. Lieutenant Colonel Voncken of the Belgian army medical corps emphasized the importance of the plans for humanizing war, launched through the initiative of the prince of Monaco. By creating a commission of jurists and physicians, he has merited the gratitude of the world. Professor de La Pradelle called attention to the heavy duties that rest on those who assume charge of international conferences. He recalled the efforts made in 1874, 1904 and 1907 at The Hague and Geneva and expressed the view that the codification of the rules of warfare is indispensable. In case of violations of accepted rules by a belligerent, he demanded reprisals authorized by the neutral powers.

Among the most important communications may be mentioned first, "Organization of the Sanitary Service Back of the Lines," by Colonel Schickel of the French army. About two thirds of the men evacuated from the front are conveyed to the interior of the national territory in order that they may find the best conditions for recovery.

The large number of casualties resulting from modern warfare demands extensive hospital facilities, which must be organized in accordance with an approved industrial plan, with specialization and division of labor. Such installations cannot be made rapidly unless adequate resources are immediately available. Important differences may exist in the various countries. In France the organization is according to military regions, each of which comprises three or four departments of France. Each region is divided into a number of hospital sectors, usually one for each department, each sector having from 4,000 to 5,000 beds. Each sector must have six technical centers, three of which should be medical and three surgical. The centers are all under the direction of qualified specialists. One of the hospital sectors of the region contains, in addition, eight technical centers for the medical and surgical specialists and a laboratory of bacteriology and chemistry. Then, finally, certain regions have interregional centers for the less common specialties.

All persons evacuated from the front are brought to a technical center, where they are examined by a specialist who may either retain them for treatment in his department or may transfer them to a branch functioning under his supervision. This system is in use in both the permanent and the temporary hospitals. The smooth working of the whole system is effected through the aid of technical and administrative heads, who work in close connection with one another. The persons evacuated from the armies must follow a line of communication on which function the various control and revision outfits of the sanitary trains. The first of these outfits encountered in the territory of a region constitutes a "distributing station." A physician serving as distributor meets all the transport trains from the front, and being informed as to the hospital accommodations in each sector, distributes the trains in such a manner that the train load may be entirely absorbed by one or more hospitals, in which the persons evacuated may be hospitalized and treated without loss of time.

The risks of aerial bombardment will increase the needs of hospitalization in the interior. It is impossible to estimate the needs at present, but they might be great. The problem of securing an adequate technically trained personnel will arise which opens the question of the possible utilization of medical aid of nonbelligerents. It is eminently desirable that the laws

of future warfare shall protect civil populations against aerial bombardment.

All these problems, first launched at Liege, Brussels and Madrid, received serious consideration at Monaco. Movements for the practical solution of these problems were set on foot, and great honor is due the permanent committee of the *Congres internationaux de medecine et de pharmacie militaires* for having played a prominent part in elaborating the plans.

#### MOTORIZED UNITS IN OPEN WARFARE

General Hiesco of the Rumanian army presented a paper on the use of motorized units in open warfare. Motorization permits not only a reduction of necessary equipment and saving of time but also rapid transportation of the wounded and the gassed to points outside the bombarded area. Mechanical traction, however, cannot be applied to the sanitary equipment of all the units. It is inapplicable to regimental units because of the rough terrain. To the divisions and to the army corps, on the other hand, motorization can render great service by accelerating the distribution and the transportation of the wounded and the gassed to points of safety back of the front lines. Such equipment will make it possible also to station the division and army corps ambulances much farther back where they will be less exposed to artillery fire.

#### VACCINATIONS

Col Clement Zrunek of the Czechoslovakian army presented a paper on "Vaccinations from the Point of View of Legislation." Vaccination for soldiers is only exceptionally prescribed by law. Usually it is based on ministerial orders. Under these conditions, what action should be taken if a soldier refuses to allow himself to be vaccinated? An inquiry on the subject sent to various countries, in connection with smallpox vaccination, makes it possible to divide the armies into three groups: (1) countries with revaccination prescribed by law for all subjects aged 20 to 21 (France, the Union of Socialist Soviet Republics, Uruguay), (2) countries having the same law but with special stipulations for the army (Norway, Brazil, Rumania, Sweden and Turkey), and (3) countries in which vaccination is prescribed only by ministerial decrees and military regulations (most of the other countries). France and the United States were about the only countries that made vaccination obligatory against diseases other than smallpox. Czechoslovakia is about to enact a law making smallpox vaccination obligatory and permitting the minister of national defense to adopt such measures as he shall deem necessary for protection against other infectious diseases.

#### THE TRAINING OF MILITARY PHYSICIANS

Commandant Jimenez Arrieta of the Spanish army presented a paper on the "Professional Training of Military Physicians." The methods used in Spain have given good results not only from the point of view of recruiting but also as to the quality of the physicians enlisted. Since 1908, special courses in bacteriology, surgery, otorhinolaryngology, ophthalmology, and the like, have been regularly established for the benefit of medical officers. The courses in surgery given at the Military Hospital in Madrid extend over two years and are divided into five periods. The courses in radiology and electrotherapy given in Madrid extend over a period of six months. The medical specialists trained in these courses are used in their several capacities as need arises. The personnel specializing in bacteriology, laboratory analysis and disinfection is handled, however, in a special manner and is held to the study of the following problems: hygiene, alimentation, housing, and choice of clothing and other equipment for the soldier; bacteriologic, histologic and physicochemical analysis, medicolegal relationships, prophylaxis, elaboration and preparation of various vaccines and serums and veterinary hygiene.

In addition to these courses, in order to enable the medical officers to practice in a military environment, they must attend the special continuation courses that are obligatory for the heads of departments and for the officers of all armed units and all army corps, which comprise three periods: one preparatory, one of practical execution, and a third of advanced training.

In addition to technical papers, the meeting was devoted to the preliminary plans for an international convention, 'as elaborated in Monaco last February, the purpose of which is to humanize war', that is to say, to diminish, in the event of a future war, the evils and rigors not only for the belligerents themselves but also for the civil population from the use of engines of war with frightful powers of destruction.

The question was first brought up in 1933 at the seventh Congress of Military Medicine, in Madrid. The congress passed several resolutions endorsing the idea. To work for its realization, the prince of Monaco summoned a commission of fourteen members, composed chiefly of the delegates of the permanent committee of the Congress of Military Medicine and in addition, of several eminent specialists in international law. The conference resulted in a plan for an international convention to be submitted to the various countries for acceptance at a diplomatic conference to be held later. Five features of the plan are worthy of examination.

#### ORGANIZATION OF "SANITARY CITIES AND LOCALITIES"

The proposed plan provides for the creation of 'sanitary cities' at some distance back of the fighting area, and localities near the battle front, which will enjoy special protection on condition that they are used exclusively for the needs of the army medical corps.

#### SANITARY AID FURNISHED BY NONBELLIGERENTS

Lest the sanitary units find themselves unable to cope with their stupendous task, the Monaco commission proposed that they be permitted to solicit aid from neutral nations as regards both personnel and equipment.

#### TREATMENT OF PRISONERS OF WAR

The proposals in connection with the treatment of prisoners of war supplement the Geneva Convention of July 27, 1929. The sanitary aid to be given prisoners should be furnished as soon as possible by the army medical corps of the nationality of the prisoners or, in its absence, by the army medical corps of a neutral country.

#### PROTECTION OF THE CIVIL POPULATION

Protection of the civil population would be assured in part by the organization of 'cities of safety' in which the civil population might find refuge and protection against the dangers of military operations.

#### PENALTIES FOR VIOLATING THE CONVENTION

The chief penalties for violation of the convention would be reprisals after confirmation of the facts by a commission consisting of nonbelligerents, the possibility of appeal to the permanent court of international justice and withdrawal of sanitary aid from the country violating the convention.

The faculty of law of the University of Liege aided in preparing the way for the diplomatic conference proposed. Mr. Ernest Mahiam, professor of international law at the University of Liege, was elected chairman of the special section and Mr. Fernand Dehousse, assistant professor of international law at the same university, was appointed secretary. The proposed plan is not a thrust against the rights of belligerents. To say that violence cannot be made subject to rules and regulations is moreover, untenable. It is the essential purpose of all law—international law as well as domestic—to react against violence. There is an increasing trend toward international organization and toward the juridical organization of the world.

At the close of the session of the "juridical section, the permanent committee of the International Congress of Military Medicine and Pharmacy, desirous of retaining and of developing further the collaboration of the physicians and the jurists which has given such good results, decided to establish the Commission medico-juridique d'etudes charged with arousing the public opinion necessary for the success of the conference to be held in 1935. This commission, which comprises six physicians and four jurists, belonging to seven nationalities, is under the chairmanship of General Castillo Najera of the Mexican army medical corps and ambassador from Mexico at Paris and Vienna.

#### The Hospital Lottery Racket in Australia

Economic stress has driven an ever increasing proportion of the population to the public hospitals in Australia. In spite of the efforts at collection of fees from the inmates by the hospital authorities, these institutions have found themselves in financial difficulties. Voluntary subscriptions have almost dried up, and an appeal to the government was the only alternative. The government, in its turn, was also in difficulties and was not prepared to increase the load of taxation.

In Queensland since 1920 the government has conducted a lottery known as the golden casket which has provided a total sum of over £3,000,000 for medical "charities." It is interesting to note that of the total receipts from the lottery 53 per cent is returned as prizes, 20 per cent is absorbed in expenses, and 27 per cent is available for distribution. A considerable portion of the money collected came from New South Wales and in fact, all over the world.

In 1932 the New South Wales government, in face of considerable opposition from the churches, commenced lottery operations on its own account. The opposition has had the effect of curtailing the activities of the director of the lottery. No advertising is permitted and the tickets are limited to five shillings and threepence. The Queensland lottery suffered when New South Wales commenced operations but, taking advantage of the restrictions fettering the latter, Queensland instituted a second lottery with £1 tickets. Five of these were held, and £50,000 in each was subscribed in New South Wales.

This has given considerable anxiety to the minister for health and others, and demands have been made that the restrictions should be removed from the New South Wales lottery so that it may be able to withstand the competition. Statements have been issued in the press strongly defending the lottery on the grounds of expediency and urging that, since it is much less likely to cause ruin to the public than betting and horse racing, these should first be eliminated.

Another aspect of the lottery that is causing concern is the number of lottery shops that have sprung up. These sell one-seventh share in a ticket for a shilling, thus making a profit of 1/9d on each ticket. It is estimated that at least £100,000 a year is lost to the lottery in this way. An attempt was made to prevent this practice, but on an appeal to the courts it was upheld as being perfectly legal. It is stated to be the intention of the state parliament at its next sitting to declare the sale of share tickets in this way illegal and also to prohibit the gift of shares in lottery tickets as bonuses to those buying goods in shops, at present a common practice.

In Queensland the sale of share tickets of one shilling upward has assumed the proportions of an industry. About every tenth shop in the state is engaged in this business. As a means of financing capital and maintenance funds of hospitals the lottery system is a definite success, but there is a strong body of "silent" opinion that is ashamed of the method.

## Marriages

GEORGE EDGAR ROY ANTHONY, Detroit to Miss Helen Elizabeth Rose Burgess of Port Lambton, Ont., September 5

J. FRANK HICHSMITH JR., Fayetteville, N. C., to Miss Cornelia Murdock McIntyre of Bennettsville, S. C., July 25

GERALD WELDON HAYES, East Orange, N. J., to Miss Florence Margaret Auth of South Orange, September 15

SVEN MARTIN GUNDRSON, Brookline, Mass. to Miss Harriet Elizabeth Adams of Hancock Point, Maine June 21

GILBERT B. SALTONSTALL, Charlevoix, Mich. to Miss Charlotte C. Mathauer of Grosse Pointe Park July 2

ROBERT C. THOMPSON, Cumberland, Wis. to Miss Alberta Shelby of St. Paul at Duluth, Minn., June 9

WILLIAM C. HICHSMITH, Fayetteville, N. C., to Miss Margaret Parker Bridger of Bladenboro, July 25

WILLIAM MCNEILL CARPENTER to Miss Nena Martin McSwain, both of Greenville, S. C., July 21

GEORGE ARLIN BAVIR, Pennsburg Pa., to DR. FRANK FRANCES HOPKINS of Boston, September 1

HOMER MILTON FARLE, Orangeburg, S. C., to Miss Claribel Croswell Parham of Charleston July 12

LAWRENCE FRANCIS DUGAN, Faribault, Minn., to Miss Margaret Lucille Malone of Owatonna July 13

FRED HIGGINS BEALMONT, Council Bluffs Iowa, to Miss Virginia Kiddoo of Elmwood, Ill., July 21

ROCCO JOHN ROMANELLO, Hartford, Conn. to Miss Alice Bernadine Gaffney of New Britain, July 16

THEODORE DWIGHT STEVENSON to Miss Beatrice Elmore Scott both of Holyoke, Mass. September 8

PALMER R. KUNDERT, Madison Wis. to Miss Kathryn Elizabeth Mauermann of Monroe, June 19

WILLIAM JACKSON COPLAND, Cary, Ill., to Miss Jeanne Alme of Rhinelander, Wis., September 7

FLETCHER GORDON KING, St. Augustine, Fla., to Miss Evelyn Walters of Lavonia, Ga., recently

LEWIS J. GREENFELD, Center Colo. to Miss Rosemary Kalb of Brooklyn in New York June 23

ROBERT C. ANDERSON, Newark, N. J., to Miss Elsie May Parker of Washington, D. C., June 12

JEROME PIERCE WEBSTER to Miss Geraldine Rockefeller McAlpin both of New York, July 14

CHARLES FRANKLIN FISHBACK, Sharon, Wis. to Miss Katharine Williamson of Madison June 24

CHARLES SOL STERN, West Allis, Wis. to Miss Ruth Schoenkerman of Milwaukee, June 17

TAYLOR WOOD GRIFFIN, Quincy, Fla. to Miss Helen Eldridge of Idabel, Okla., June 20

WILLIAM A. CARRIGAN, Beaufort, S. C., to Miss Benlah Womack at Society Hill, July 28

JOHN HENRY DOUGHERTY to Miss Florence Mabel Boone both of Asheville, N. C., July 28

PORTER CORNELIUS PENNINGTON Findlay, Ohio to Miss Cleo Elizabeth Slagle, August 6

ALBERT JEFFERSON MCILWAIN to Miss Virginia McKinsey both of Merigold Miss., June 6

LOVETT MARTIN REAVES, Dallas, Texas to Miss Allan Wells in Hope, Ark., July 15

HENRY LEWIS GREENE to Miss Isabelle Winterbotham both of Madison Wis., August 7

NORRIS H. FRANK, Buffalo, to Miss Donna Gilliland of Conneaut, Ohio, August 12

LOUIS RICHARD BOWEN, Eustis Fla., to Miss Myra Sadler of Jacksonville, August 10

WILLIAM L. HOBART, Lakewood, Ohio to Miss Eunice Reed of Pomeroy, July 11

JOSEPH RAY JOHNSON, Cleveland to Miss Madge Webster of Shaw, Miss. recently

ARTHUR R. SIMON to Mrs. Mary J. Gardner both of La Porte, Ind., July 19

LAMAN ALEXANDER GRAY, Baltimore to Miss Alice Virginia Crothers, June 4

THEODORE M. PAULBECK to Miss Helen A. Schulze, both of Milwaukee, May 12

CLIFFORD JAMES PITTMAN, Ruleville Miss. to Mrs. Addie Sue Young July 29

## Deaths

Edward Francis Kilbane ☉ New York, Cornell University Medical College, New York, 1901, member of the American Urological Association and fellow of the American College of Surgeons, served during the World War, on the staffs of the Misericordia Hospital, City Hospital, Roosevelt Hospital, St. Mary's Hospital for Children, Flushing (N. Y.) Hospital and Dispensary and the Lincoln Hospital, aged 57, was killed August 18, in an automobile accident in St. Albans, Vt.

James Wilson Du Comb, Carlyle, Ill., Barnes Medical College, St. Louis, 1905, member of the Illinois State Medical Society, formerly mayor and member of the board of education of Beckemeyer, aged 62, died, July 24 of arthritis as the result of injuries received in an automobile accident which occurred several years ago

Samuel S. Coe, High Point, N. C., University College of Medicine, Richmond, 1911, member of the Medical Society of the State of North Carolina, physician to the High Point College on the staff of the Guilford General Hospital, aged 53, died, August 6, of complications following an operation for appendicitis

Charles Richard Marsh, Oneonta, N. Y., Albany Medical College 1903 member of the Medical Society of the State of New York, fellow of the American College of Surgeons, aged 54 on the staff of the Aurelia Osborn Fox Memorial Hospital, where he died, July 11, of chronic nephritis and heart disease

James Fitz Taylor, Sioux City, Iowa, Bellevue Hospital Medical College, New York, 1892, member of the Iowa State Medical Society, fellow of the American College of Surgeons on the staffs of St. Joseph's, Mercy, St. Vincent's, Lutheran and Methodist hospitals, aged 67, died, July 1, of heart disease.

William Oakley Kemper, Reading, Ohio, University of Cincinnati College of Medicine, 1932, member of the Ohio State Medical Association and the Associated Anesthetists of the United States and Canada aged 26, died, July 30, in the Christ Hospital, Cincinnati, of septicemia

Grover Cleveland Blake ☉ Cumberland Md., College of Physicians and Surgeons, Baltimore, 1910, fellow of the American College of Surgeons, aged 50, on the staff of the Allegany Hospital of the Sisters of Charity, where he died, recently of carcinoma of the stomach

Harvey W. Garrison, Hillview, Ill., Barnes Medical College, St. Louis, 1906, also a pharmacist, member of the Illinois State Medical Society formerly member of the school board, aged 53 died August 6, of carcinoma of the rectum with metastases to the liver and lungs

Samuel Edward Teague, Hamlet N. C., Tulane University of Louisiana School of Medicine, New Orleans 1921, member of the Medical Society of the State of North Carolina aged 37, on the staff of the Hamlet Hospital, where he died August 10 of osteomyelitis

William LaFayette Gossage, Kennett Mo. St. Louis College of Physicians and Surgeons, 1905, member of the Missouri State Medical Association, past president of the Dunklin County Medical Society, aged 67 died, July 9 of pulmonary tuberculosis

Benjamin Gutmann ☉ New Brunswick, N. J., Jefferson Medical College of Philadelphia, 1897, fellow of the American College of Physicians, on the staffs of St. Peter's General and Middlessex General hospitals, aged 56, died August 7, of bronchogenic carcinoma

Walter J. Foster, Lansing Mich., Cleveland College of Physicians and Surgeons, Medical Department of the University of Wooster 1884 aged 72 died, August 17, in the Edward W. Sparrow Hospital, of injuries received when he fell from the roof of his home

James Davidson Iglehart, Baltimore, University of Pennsylvania School of Medicine Philadelphia, 1875, member of the Medical and Chirurgical Faculty of Maryland, aged 84, died July 14 in the Union Memorial Hospital, of bronchopneumonia

Victor Joseph Girardi ☉ North Adams, Mass., Harvard University Medical School, Boston 1924 member of the school board on the staff of the North Adams Hospital, aged 34, was drowned August 1 in the Windsor Pond at Plainfield

Chester L. Stocks, Bushong Kan., University Medical College of Kansas City 1896, member of the Kansas Medical Society, aged 66 died suddenly, August 3, in the Newman Memorial County Hospital Emporia of diabetes mellitus

**John Edward Connor**, Rochester, N Y, Georgetown University School of Medicine, Washington, D C 1904, member of the Medical Society of the State of New York, aged 55, died, August 10, of chronic nephritis and myocarditis

**George Tucker Spencer**, Dallas, Texas, Baylor University College of Medicine, Dallas, 1920 member of the State Medical Association of Texas, served during the World War, aged 43, died, August 6, of heart disease

**William David Guttery**, Pilger, Neb., Lincoln (Neb.) Medical College of Cotner University 1901, at one time superintendent of the Norfolk (Neb.) State Hospital aged 82 died, July 11, of prostatic obstruction

**John Louis Moorhead** ♂ Neodesha, Kan. Kansas Medical College, Medical Department of Washburn College Topeka 1896 for many years member of the board of education, aged 64, died, July 13, of heart disease

**John Albert Kimzey** ♂ Detroit, College of Physicians and Surgeons, Baltimore, 1910, veteran of the Spanish-American War, aged 57, died suddenly, July 23, at the Belle Isle bathing beach, of coronary thrombosis

**Moses Wolff Gordon**, Jamaica, N Y, Rush Medical College, Chicago, 1933, member of the Medical Society of the State of New York, aged 25, died, August 5, of coronary sclerosis and acute myocarditis

**Frederick W Stewart**, Coldwater, Mich., Cleveland Medical College, 1891, at one time city health officer formerly on the staff of the Branch County Infirmary and Hospital aged 73, died, August 14

**Henry Chester Jackson**, Woodstock Vt., Dartmouth Medical School Hanover, N H, 1897 member of the Vermont State Medical Society, aged 70, died, July 13, of prostatitis and myocarditis

**Herbert Arthur Rhoades** ♂ Foster Mo. Kansas City (Mo.) Medical College, 1897, bank president aged 65, died August 3 in the Mercy Hospital, Fort Scott, Kan., of uremia and chronic nephritis

**Eugene Aloysius Sturm** ♂ Jasper, Ind. Kentucky School of Medicine, Louisville, 1904, past president of the Du Bois County Medical Society, served during the World War aged 55 died, August 10

**Henry A Broad**, Chicago, Illinois Medical College, Chicago 1909, on the staff of the Lutheran Memorial Hospital aged 63, died, September 6 of hypostatic pneumonia and coronary thrombosis

**George Arthur M Eychaner** ♂ Naima, Mich., University of Nebraska College of Medicine, Omaha, 1926 aged 33 died suddenly, July 23, in the Pinecrest Sanatorium, Powers of diabetes mellitus

**William Jeremiah Taylor**, Everett Mass. Tufts College Medical School Boston, 1932, intern at the Brooklyn (N Y) Eye and Ear Hospital aged 31, died, July 12, in the Malden (Mass.) Hospital

**Charles Harris Latimer**, Laurel Md. College of Physicians and Surgeons, Baltimore, 1881, on the staff of the Laurel Sanitarium, aged 73, died, July 29, of heart disease and arteriosclerosis

**Charles Henry Jahn**, North Milwaukee, Wis. Rush Medical College, Chicago 1895, formerly on the staff of St Joseph's Hospital Milwaukee, aged 65 died suddenly, July 25 of heart disease

**John Williamson Price**, Denver, Memphis (Tenn.) Hospital Medical College, 1903, aged 53, died, August 6 in Colorado Springs, of chronic nephritis, pneumonia and chronic myocarditis

**Ralph Henry Goldberg**, New York University of Vermont College of Medicine, Burlington 1895 aged 62 died August 8 in the Veterans' Administration Facility of chronic myocarditis

**Gustav Koehler** ♂ Chicago, Julius-Maximilians-Universität Medizinische Facultät, Würzburg Bavaria 1895 aged 68 died, August 5, in the Grant Hospital, of carcinoma and embolism

**Otto John Gutseh**, Sheboygan Wis. College of Physicians and Surgeons, Medical Department of Columbia College New York 1886, aged 69, died August 11 of cirrhosis of the liver

**George Myers Godfrey**, San Antonio Texas, National University Medical Department Washington D C 1896 aged 64, died June 26, of pulmonary tuberculosis and nephritis

**Allen T Hays**, Vernon, Texas (registered by Texas State Board of Medical Examiners under the Act of 1907) aged 46 died in August of a skull fracture sustained in a fall

**George L Madison**, West Chicago, Ill., Bennett College of Eclectic Medicine and Surgery, Chicago, 1877, aged 85, died, June 7, of acute hepatitis, jaundice and acute cholecystitis

**James Henry Thompson**, Pittsburgh, Hahnemann Medical College and Hospital, Chicago, 1886, aged 75, died, July 12, in the Homeopathic Medical and Surgical Hospital

**Charles E Frost**, Cottage Grove, Ore. (licensed in Oregon in 1912) served during the World War health officer, aged 57 died suddenly July 30, of coronary thrombosis

**Eugene K Whidden**, Pensacola, Fla., Georgia College of Eclectic Medicine and Surgery, Atlanta, 1910, aged 45, died, July 30 in the Pensacola Hospital, of pellagra

**Leo F Towers**, Toledo, Ohio. Physio-Medical College of Indiana, Indianapolis, 1880 aged 74 died, August 13, of carcinoma of the colon and coronary thrombosis

**John Melvin Thompson**, Graham, N C. University of North Carolina School of Medicine, Chapel Hill, 1909, aged 46, died, July 14, of pulmonary tuberculosis

**John Calhoun Griffies**, Carrollton, Ga., Atlanta Medical College, 1890 member of the Medical Association of Georgia aged 74, died, July 26 of acute nephritis

**George Brinton McClellan**, Weir, Kan. Northwestern Medical College St Joseph 1894, aged 69, died, July 22, in the Mount Carmel Hospital, Pittsburg

**James Thomas Suggs**, Cleveland, Howard University College of Medicine, Washington, D C, 1903, aged 56, died, August 20, in the Lakeside Hospital

**Max Henry Bracker**, New York. Columbia University College of Physicians and Surgeons, New York, 1902, aged 56, died, August 8, of heart disease

**Hamlin Collier Cook**, Cedartown, Ga., Georgia College of Eclectic Medicine and Surgery Atlanta, 1888, aged 75, died July 3, of chronic myocarditis

**Frederick Gustave Eidman Sr** ♂ Houston, Texas, University of Texas School of Medicine, Galveston, 1896, aged 59, died, August 4, of chronic nephritis

**John Maxwell Heading**, Johnstown Pa., College of Physicians and Surgeons, Baltimore, 1886, aged 78, died, August 15, of chronic myocarditis

**James Enos Butler**, Dallas, Texas, Kentucky School of Medicine, Louisville, 1895, aged 77, died, August 8, of coronary disease and arteriosclerosis

**Walter Brainerd Allen**, Red Bank, N J., University of Vermont College of Medicine, Burlington, 1900 aged 61 died, August 11, of heart disease

**James Peyton Curlee**, Woodbury, Tenn., Vanderbilt University School of Medicine, Nashville, 1879, aged 76, died, August 15, of chronic nephritis

**William R Mizell**, Shelbyville, Ill., Miami Medical College Cincinnati, 1874, Civil War veteran, aged 94 died, August 1, of senility

**Ernst Zille**, Egg Harbor City, N J., Baltimore University School of Medicine, 1897, aged 83, died, July 25, of chronic myocarditis

**John Cearnas Jolly**, Rockport, Ind., Kentucky School of Medicine, Louisville, 1885 county auditor, aged 76, died, July 23, of heart disease

**Alfred Gates**, Lebanon Pa. Hahnemann Medical College and Hospital of Philadelphia, 1890, aged 64, died, August 10, of heart disease

**Alfred T Wright**, Waynesville Ohio Jefferson Medical College of Philadelphia, 1876, aged 81, died, August 15, of myocarditis

**George Michael FitzGerald**, Brooklyn, Long Island College Hospital, Brooklyn, 1892, aged 64, died, July 29, of leukemia

**Hyram G Brooks**, Likhorn, Tenn. University of Tennessee Medical Department, Nashville 1890, aged 75, died, July 20

**Charles Edward Cutler**, Magnolia Iowa, Pulte Medical College Cincinnati 1878, aged 83, died August 8, of hemiplegia

**Joseph Henry Gerass** ♂ Westfield, N Y., University of Buffalo School of Medicine, 1927, aged 35, died July 8

**Charles Alexander Shaeffer**, Lees Creek, Ohio, Baltimore Medical College 1893 aged 67, died, August 17, of carcinoma

**Bernard Anthony Maffucci**, Dunmore, Pa., Temple University School of Medicine, 1923 aged 35 died July 22

**Gus A Hardwick**, Utica Ky., Louisville Medical College 1874 aged 83 died July 21 of senility

## Correspondence

### ANTIQUITY OF QUINTUPLETS

*To the Editor*—The following excerpt from Rolfe's "Attie Nights of Aulus Gellius" (volume II, p. 217), a judge in the courts during Galen's residence in Rome, appears apropos

The philosopher Aristotle has recorded (Cf. Hist. Anim. vii, p. 584, 29) that a woman in Egypt bore five children at one birth; this, he said, was the limit of human multiple parturition; more children than that had never been known to be born at one time and even that number was very rare. But in the reign of the deified Augustus the historians of the time say that a maid servant of Caesar Augustus in the region of Laurentum brought forth five children and that they lived for a few days; that their mother died not long after she had been delivered; whereupon a monument was erected to her by order of Augustus on the via Laurentina and on it was inscribed the number of her children as I have given it.

JOSEPH WALSH, M.D., Philadelphia

### FEES FOR CWA SERVICE

*To the Editor*—Dr. Leslie W. Beebe's communication regarding chiseling insurance companies (THE JOURNAL, September 15) interests me because of a similar recent experience with the U. S. government.

February 1, a man who operates an elevator in the building of the Workmen's Compensation Department at 80 Eighth Avenue, New York, was referred to our office for a roentgen examination of the left little finger because of an injury that produced a fracture. The report was made to the referring physician and a duplicate sent to the medical supervisor and documents were filled out in triplicate, not only once but several times. This was the first of eight cases referred to us by the CWA, and after getting nothing out of any of them except more and more documents to fill out in triplicate, some of them with the physician's name inserted by the CWA office in the space where the claimant's name belonged, I wrote to the CWA office and said: "Both Dr. Lewis and I will be most grateful if you will see that our names are taken off of the list of x-ray men for CWA work because the red tape involved in getting paid for these cases is more trouble than the small receipts are worth."

Except for an occasional request for more documents to be executed in triplicate, we heard nothing from the CWA on any of these cases until September 14, when the bill for \$5 for roentgenographing the man's finger was rewarded with a check from the Office of the Chief of Accounts, U. S. Employees' Compensation Commission, in the amount of \$3.15, together with the following mimeographed slip:

The Commission is allowing your voucher rendered in this case at a lower rate than charged by you. It is realized the fees allowed in this case may be lower than the usual fees charged to the average private patient. However, it must be borne in mind that the setting up of the Civil Works Administration program with the allowance of compensation benefits will to some extent relieve the medical profession of the burden of free treatment. In view of the Federal employment of these people as a relief measure it is not believed the average fees generally charged in each locality are warranted. You will probably find the fees allowed in this case are not less than the fees you charge a private patient in the same income class as the injured employee or the minimum fee schedule of your county Medical Society. They can be compared favorably with fees allowed for medical treatment of the unemployed under authority of the Federal Emergency Relief Administration.

The casualty insurance companies operating in New York City are not noted for their benevolence toward the medical profession, but they always pay \$5 for a roentgen examination of a finger, even when it is only the little finger. I was once favored with the x-ray work of the New York Edison Company until an advertising commercial laboratory took it over, and it never paid less than \$5 for a roentgen examination of any part of the body. For the U. S. government to imply that \$3.15 is as much as I ought to expect to get for roent-

genographing a finger impresses me therefore as nothing but the vaporings of some bureaucratic mind.

I have accepted the \$3.15 on account, and endorsed the check to that effect, though I do not expect to live long enough to get the other \$1.85. (There are seven other cases yet to be heard from.) \$3.15 is 63 per cent of \$5. When the next income tax payment is due, I intend to submit 63 per cent of the amount assessed by the government and tell them that as they have reduced my claim in this proportion it is surely only fair play for me to reduce their claim in the same degree. I shall report later on how I make out on the test case.

RAMSAY SPILLMAN, M.D., New York

## Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

### ELECTROCARDIOGRAPHY

*To the Editor*—For no special reason except that I had about two months' experience with an electrocardiograph four years ago I have been appointed to a committee to study the advisability of the purchase of such a machine by our local hospital. Ours is a city of some 25,000 with a rather high general average population. Twenty miles away there are three or more able heart specialists with electrocardiographs. Our hospital has about 125 beds. It is the feeling of some of the men that at least a thousand dollars a year is going to heart specialists in another city that might well stay here. Furthermore there are numerous cases in the wards in which we would benefit, we think by having a machine. Of course we realize that even though we had a machine a considerable number of residents would continue to go elsewhere for electrocardiography as they do for other medical services. We realize also that far from making a profit for the hospital our first care would be to cover the interest charges. I would appreciate your listing the conditions in which you feel that an electrocardiograph is relatively essential for diagnosis or prognosis. Do you feel that the city and the hospital are large enough so that we could reasonably expect to cover expenses? I would appreciate your naming a book or monograph that presents the subject in a satisfactory manner. If we purchase a machine I may be the one who runs it and tries to interpret the results. As I have stated I have had just enough experience to make me realize how little I know about the subject. Please omit name and town.

M.D., Massachusetts

**ANSWER**—An electrocardiograph is by no means a necessity and gives relatively little of clinical importance that cannot be gained by the hand and ear aided by clinical experience. Perhaps its greatest value is in confirming the clinical experience. It gives a graphic record which confirms the clinical diagnosis and serves as a check on what one does and does not know. Its teaching value in differentiating arrhythmias would be a sufficient reason for its installation. There are some conditions in which it is essential for diagnosis, as in bundle branch block, and is of great assistance, as in coronary disease and coronary accidents. It is frequently difficult or impossible to make a positive diagnosis of a number of the more frequent arrhythmias without its use. Premature auricular and premature ventricular contractions can often be differentiated clinically but not always with accuracy.

An institution of the type described should have an electrocardiograph. A portable string galvanometer is the best when only one machine is to be installed. Its operation is not difficult and can be mastered in a short time. The new instruments are easy to manipulate and almost impossible to damage. The interpretation of the electrocardiograms offers more difficulty but can readily be mastered with time and experience. If one confines oneself to the data of known clinical value, the interpretation is not a difficult task.

The cost of operation is small and the apparatus should not only pay maintenance and interest charges but pay for itself in a short time. It is much better for financial reasons, as well as from the standpoint of service to the physician and the patient to make the cost to the patient small and depend on a large volume of work.

The operator should familiarize himself with and have available for constant use "The Mechanism and Graphic Registration of a Heartbeat" by Thomas Lewis. In addition there are many other excellent works that he may use.

# AMENORRHEA AND MENSTRUAL IRREGULARITIES

*To the Editor*—A patient white aged 19, started to menstruate at the age of 13. The menstruation has been of an irregular type. An apparently normal flow of moderate amount lasting for from four to five days is usually followed by a period of three to four months in which no menses occur. There is nothing abnormal in the past generation, so far as is known the mother and sisters menstruate normally. The patient measures 5 ft 6 in (167.6 cm) in height and weighs 118 pounds (53.5 kg). She has no physical defects. Examinations of the neuro-muscular respiratory and circulatory systems are negative. The blood examination shows red blood cells 4,800,000 white blood cells 6,200 hemoglobin 85 per cent, and the differential count is normal. Urinalysis is negative. The gastro-intestinal and genito-urinary systems are normal. There have been no operations. Bimonthly pelvic examination reveals no pathologic masses or discharges. Treatment during the past eighteen months has consisted of a drug to stimulate the formation of hemoglobin. Two bormotone tablets taken three times a day following the use of 300 mg. bormotone tablets 100 progynon tablets were given. The treatment has produced no results and the patient has not menstruated since February 2 to February 7. Are endocrine dysfunctions usually the cause of functional amenorrhea? What suggestions have you for the management of this type of case.

M D Wisconsin

*ANSWER*—In the process of menstruation at least three organs are involved the pituitary gland, the ovaries and the uterus. Rhythmic bleeding from the uterus is nearly always dependent on the proper functioning of the ovaries, and the latter in turn are controlled by the anterior lobe of the pituitary gland. The pituitary gland is therefore the regulator or as Zondek called it, the motor of the ovaries. It is not known why some women have a twenty-eight day menstrual cycle, others a thirty day cycle, and still others further variations in the menstrual cycle. To produce uterine bleeding in women with amenorrhea is generally easier than to change the interval at which menstrual periods occur. Furthermore, it must be understood that not all bleeding that follows medication is actual menstruation. Likewise, in most cases in which bleeding is produced by medical measures the flow of blood is only temporary and does not recur unless more medication is employed. Estrogenic preparations, such as theelin, progynon and others do not stimulate the ovaries. On the other hand estrogenic substance administered to women with functioning ovaries may do harm. In the case cited there is no need to employ expensive and unproved remedies in an attempt to bring about more frequent menses. This patient does not have amenorrhea (complete suppression of the monthly flow). She may be honestly told that she is as healthy as women who menstruate every month and therefore nothing need be done to make her menstruate more often.

# TELANGIECTASIA AFTER ACTINIC EXPOSURE

*To the Editor*—A woman aged 25 whose history is negative after quite a prolonged exposure to the sun four years ago noticed a red mottled discoloration of the outer surface of both forearms. It looks exactly like a nevus or birthmark, and on close examination the dilated capillaries may be seen. It remains the same winter and summer and seems to be spreading. At present when it is exposed to the sun it burns intensely. It looks something like the telangiectasia seen after the use of x-rays by Tricho operators but she has had nothing of that sort done. I should like to know what this is and if there is any way of getting rid of it. It is quite disfiguring.

KATHRYN M. WHITTEN M D Fort Wayne Ind

*ANSWER*—It is possible that the exposure to the sun was the determining factor in causing the patches of telangiectasia but there must have been a predisposition present some weakness of the small blood vessels of the skin, or their nervous apparatus, which made them more than normally susceptible to actinic irritation. Telangiectasia occurs on the face secondary to habitual exposure to the sun, but only in certain skins in which the pigmentary protective apparatus is defective. Areas of telangiectasia on the forearms indicate great susceptibility in the skin of that region.

The patient therefore, should be studied for possible causes of vascular disturbance. Syphilis, liver, cardiac or kidney disease, hyperthyroidism, pituitarism or other endocrine abnormality, Raynaud's disease, arteriosclerosis or leukemia should be considered. If with the dilated vessels there are spots of atrophy and pigmentation causing a close resemblance to roentgen telangiectasia a rare skin disease known as poikiloderma atrophicans vasculare is a possible diagnosis. Some of the cases have been associated with internal malignant growths. Others show no such relationship (Lane, J E Poikiloderma Atrophicans Vasculare, *Arch Dermat & Syph* 4 563 [Nov] 1921).

If the telangiectatic patches cannot be improved by treatment of some etiologic factor, roentgen treatment on fourth erythema dose (75 roentgens) of lightly filtered (1 mm of aluminum) roentgen rays once a week for four doses may be tried. If this fails, a mercury vapor quartz lamp may be pressed on a

small area long enough to produce a sharp erythema. This may result in reduction of the dilated vessels.

Carbon dioxide snow is another possibility. A small stick should be applied with firm pressure for one or several seconds to many areas, causing a mild reaction not severe enough to cause checkering.

Electrolysis may be used if the vessels can be entered by the needle carrying the negative current. From 1 to 15 milliamperes should be allowed to pass for a half minute or more until the vessel turns white then one should remove the needle without breaking the circuit in order to prevent hemorrhage.

Sodium morrhuate, 3 per cent in oil, may be injected into the vessels with a fine needle. At points at least 2 cm apart on the border of the patch 0.1 cc is used. The reaction from one treatment should be allowed to subside before another attempt is made in the same area.

# PAINFUL STUMP AFTER AMPUTATION

*To the Editor*—A man aged 30 had a crushing injury of both feet Aug 15 1932. August 17 the right foot was amputated at the junction of the middle and upper thirds of the leg. It was four months before complete healing took place in the incision. At the end of six months he started to wear an artificial leg with the weight bearing just below the knee. About three weeks after he began to use this leg an ulcer formed in the incision. The incision had a serous drainage, and he complained of burning at night when the artificial leg was off. Because the ulcer steadily increased in size he insisted on a reamputation Aug 15 1933. At the time of operation a neuroma was found. Reamputation was done 2 inches of the stump being removed. The wound healed in ten days. In November he started wearing a new artificial leg and in December two ulcers formed on the incision. These have a serous drainage but do not cause pain. He does complain however of severe pain at the end of the tibia which is covered by a good pad. Roentgen examination of the bone and blood examinations are negative. General examination is negative except for a highly nervous state. His past medical history is negative. The patient's family has been described by another doctor as highly neurotic. Boric powder in the bearing ultraviolet rays and scarlet red ointment have produced no change. Please omit name.

M D Pennsylvania

*ANSWER*—The problem is a double one. In the first place, an orthopedic surgeon has advised that when the amputation is below the knee it is important that the anterior edge of the tibia at the site of amputation be properly leveled off, that the fibula be amputated about 2½ inches above the level of amputation of the tibia and that the flap be so planned that it is neither too rigid nor too tight. Recurring ulceration may be caused by the failure to observe any one of these instructions. If the pain persists after the employment of proper orthopedic measures the nerve should be resected for 2 or 3 inches above the point of amputation. At the time the orthopedic measures are being carried out, the nerves, such as the peroneal and posterior tibial, could be exposed, dissected free ligated with fine ligature catgut and amputated so that they will draw back in the muscle planes 2 or 3 inches above the line of amputation. Occasionally, alcohol may be injected into the severed ends of the nerves, as this usually reduces the size of the subsequent neuroma.

# PREGNANCY AND HYPERTENSION

*To the Editor*—A married woman aged 42, had the usual diseases of childhood and scarlet fever while in college. Cholecystitis with stones developed and a cholecystectomy was performed in 1927. Since then she has had five or six attacks of what was apparently gallstone colic requiring morphine for relief. She has had three pregnancies two since the cholecystectomy. These pregnancies were normal except that two of the deliveries were by forceps for occiput posterior presentations which would not rotate. Recovery was normal in each case. She had two spontaneous six to eight week abortions none have occurred since the last pregnancy. The patient is now between five and six months pregnant and has a persistent systolic blood pressure of 160 to 176 mm of mercury and a diastolic pressure of 86 to 94. The urinalysis is negative. The average specific gravity is 1.018. There is no edema. There are no subjective complaints. The blood pressure has been elevated since the third month of pregnancy. About four months before she became pregnant the blood pressure was 122/80 and the pulse rate about 80. Economic conditions force this woman to do more physical work than I think advisable. A moderate amount of rest (an hour after meals) and a milk fruit and vegetable diet seem to have no effect on the blood pressure. Would you care to give me advice on the facts as stated? Please omit name and address.

M D Iowa

*ANSWER*—The patient's present condition need not give concern. Since there appear to be no objective and subjective disturbances other than an elevation in blood pressure, the outlook for continuation of the pregnancy without serious occurrences is not bad. The diet prescribed is satisfactory but there would be no harm in adding more proteins in the form of meat and eggs. It is advisable to eliminate all salt from the food. Mild sedatives, such as the bromides, should be pre-

# QUERIES AND MINOR NOTES

JOUR. A. M. A.  
SEPT. 29, 1934

## EXFOLIATIVE DERMATITIS IN INDUSTRY

scribed for a few days at a time. The patient should be watched carefully. Once a week the blood pressure should be taken the urine examined and the weight recorded. Should untoward signs and symptoms appear such as albuminuria, edema, excessive gain in weight, severe headaches, stubborn constipation and vomiting, the patient should be put to bed and given such sedatives as phenobarbital sodium and magnesium sulphate. The diet at such a time should be high in carbohydrates and it may be advisable to give dextrose intravenously. If improvement does not follow rapidly, the pregnancy should be terminated, preferably by rupturing the bag of waters.

To the Editor—The following is a report to an oil company concerning one of the men whom I examined who has dermatitis exfoliativa. His condition has continued to improve since the time of the last writing. I have the ingredients of coal tar and pine tar been known to cause a condition like this one before when one mixes them up and melts them with asbestos for insulating purposes as in this case? About April 3, the patient helped prepare some insulating material which consisted of commercial pine tar, coal tar and asbestos. The pine tar and coal tar were melted and then prepared in a box with the asbestos and stirred. On Thursday April 5 he first noticed little pimples on his fingers and both hands and they extended up the arm and over the body. On April 6 he first saw a doctor because of the rash on his hands and arms. The skin became greatly swollen and erythematous and he developed large quantities of serum oozed out. At no time was there any involvement of the kidneys or bowels. The mucous membrane of the nose and throat was never seriously involved. At present he is very much better. The swelling and edema having largely if not completely left. The skin is very rough, dry and scaly. Large flakes of skin even larger than the palm of the hand were peeling off at one time. The patient says he feels well. Since the kidneys and bowels are in good shape there seems to be no toxic involvement of the internal organs.

LELAND BAXTER M.D., Newark, Ohio

ANSWER—It is not possible unequivocally to state that local irritants such as coal and pine tars may be the direct source of dermatitis exfoliativa. Recently there was observed a fatal case of dermatitis exfoliativa in a filling station operator who was brought in contact with ordinary petroleum derivatives. In this instance there was a history of syphilis and recent previous administrations of arsenicals. Also recently a case of dermatitis exfoliativa developed in a worker engaged at the time of the onset of his illness in fruit tree spraying. It is perhaps permissible to take the stand that dermatitis exfoliativa may follow in the wake of ordinary chemical dermatoses. Long and Stelwagon after mentioning that dermatitis exfoliativa is a very rough, dry and scaly. Large flakes of skin even larger than the palm of the hand were peeling off at one time. The patient says he feels well. Since the kidneys and bowels are in good shape there seems to be no toxic involvement of the internal organs.

## NECROSPERMIA AND AZOOSPERMIA AS CAUSES OF STERILITY

To the Editor—A married man aged 35 has consulted me regarding the fact that his wife, an apparently healthy normal woman who gave birth to a son eight years ago, has not been pregnant since that time. No method of prevention of conception is used. They engage in marital relations about once every two weeks. I have had a microscopic examination of his semen within ten minutes after ejaculation. Many spermatozoa are visible but they are apparently immotile. There is no history of genito-urinary disease. Are we probably correct in assuming that the sterility is caused by the immotility of the spermatozoa? If so can you kindly advise what can be done about it? Please omit name.

M.D. Ontario

ANSWER—There is no doubt that the immotility of the spermatozoa is the cause of the sterility. It is however important to rule out a possible artificial immotility of the spermatozoa in the condom specimen. If the condom has been brought to the physician in a jar of warm water, as so often is advised to prevent chilling of the specimen, it may happen that the water is too hot, thus instantly killing the spermatozoa. Sometimes the powder that the manufacturer puts in the condom to facilitate its use contains a chemical that is inimical to the vitality of the spermatozoa. Assuming that in this case the spermatozoa are immotile when they are ejaculated it is necessary to determine the cause of the necrospERMIA. This is not always easy. The absence of a history of venereal disease does not absolve the genito-urinary system as a cause of the condition. A nonspecific seminal vesiculitis or prostatitis may kill spermatozoa as effectively as gonococci. The fluid obtained by combined prostatic vesicular massage must be carefully examined for pus cells. The presence of pus cells indicates the existence of a pathologic condition which must be found and treated. In the absence of a pathologic condition of the genito-urinary system, it is important to find out whether at any time the patient has had roentgen treatment applied to the perineum, thighs, lower abdomen or the genital organs themselves. This is a common cause for necrospERMIA and azoospermia. Modern methods must be used to determine whether there is a dis-

## LUNULA OF FINGER NAILS

To the Editor—Will you please explain the nature of the 'half moon' on the finger nail? I have a patient (coronary disease) who states that he lost all of them about a year ago. His nails and finger tips seem normal otherwise.

WILLIS P. BAKER M.D. Santa Ana, Calif.

ANSWER—The lunula ('half moon') is a more or less convex or half-moon shaped area that appears as a little white crescent in front of the nail fold at the base of the uncovered portion of the nail. It does not really end at the edge of the covering of the nail fold but extends on each side of the lateral edges of the nail. Frequently, especially on the toes, it is necessary to push back the roof of the nail fold before the lunula becomes visible. The lunula is the macroscopic expression of the matrix of the nail (Unna). The difference in color of the matrix of the nail bed is an absolute one, owing to the fact that the latter contains more blood than the former. The difference is undoubtedly due to the fact that the nail bed is covered by a transparent horny substance, whereas there are a number of absolutely opaque elements in the matrix of the nail which completely scatter the light. These are the transitional cells which are covered over and over with points that appear whiter than the granular cells by reflected light. Their presence marks the exact boundary of the lunula. Ranvier ascribes the white color of the lunula to the 'irregularity of the keratogenous cells'.

Changes in the lunula may be noted in a number of pathologic changes affecting pigmentation of the nails in disease processes that influence the consistence of the nail plate and its structure and in pathologic conditions of the nail bed in which the morbid processes take place in the region of the lunula. The nail changes in heart disease are brought forth through stasis or congestion of the venous system (J. Heller, Die Krankheiten der Nagel, Berlin, 1927). Heller states that the more common changes in the nails in heart disease are bluish discoloration (cyanosis) and hypocratic curvature. He describes a case in a woman of 50 with a patent foramen ovale and ductus botalli as well as a stenosis of the pulmonary ostium in which the finger nails were of a deep blue-black and showed the hypocratic curvature and the lunulae were not visible. Heller states that he has examined many heart cases without establishing the presence of any special changes in the nails.

## SENSITIVITY TO GRASSES AND RAGWEED

To the Editor—I have a patient, a girl aged 12 years who reacts strongly to mixed grass and ragweed. There is no other positive reaction such as food. She had an attack of hay fever and asthma last year August 1. She had hay fever this year beginning in June and asthma this year August 21. The important thing is shall I give the pollen extract for both conditions as a perennial method for one and a pre-seasonal method for the other? Kindly advise me. Please omit name.

M.D., New York

ANSWER—As this girl has both grass and ragweed hay fever there are two possible ways of treating her. She may either be given the ragweed injections now in small doses, preferably intradermally, every day or every other day, followed by increasing amounts of ragweed and continued all the year round about once in two weeks, or the ragweed may be given seasonally now and then stopped and started again next year. As the grass season is over there is no need of giving grass extract at this time. However, should the perennial treatment for ragweed be decided on it would be wise to give the grass injections at the same time so that when the grass hay fever season starts next May or June the patient will have reached a sufficiently high dosage of grass extract to give more or less protection.

Either method will probably give good results. It is to be understood of course, that the grass and the ragweed extracts should never be mixed because of the difference in the time of the year in which these weeds pollinate. It is best to give the ragweed extract in one arm and the grass extract in the other arm. The two may be given at the same time.

## TOXICITY OF VAPORS FROM ASPHALT

To the Editor—What are the harmful effects due to inhalation of gases or vapors from hot or boiling asphalt and what are the gases liberated? Please omit name  
MD Illinois

ANSWER—Asphalt is not a specific chemical. The term may be applied to natural, petroleum or coal tars of certain qualities. Chemically, all varieties are similar but not identical. This answer is directed chiefly to natural Trinidad asphalt. This fossil bituminous substance results from petroleum through the evaporation of the lighter hydrocarbons followed by the slow oxidation of the residue through the ages. When this substance is heated to high temperatures under natural pressure the vapor yield is highly complex but contains hydrogen sulphide, benzene, naphthalene, paraffin oils and various organic acids including phenol or phenol-like substances. An article entitled "Road Tar Poisoning," by Dr. Carey P. McCord (THE JOURNAL March 2, 1929, p. 695) furnishes a long list of chemicals that may be derived from asphalt as used on roads, which, however, may be coal tar rather than natural asphalt. In any event the list of derivatives is similar. These asphaltic vapors are toxic but cases resulting from exposure to them are to be accepted as from mixed poisons rather than from one precise agent.

## INDUSTRIAL HAZARDS IN HAT CLEANING

To the Editor—Kindly tell me what poison may be absorbed through the skin or inhaled in the industry of hat cleaning. I have a patient with retrobulbar neuritis and am trying to trace the cause.  
RONALD M. CURTIS MD Brooklyn

ANSWER—In the cleaning of felt hats the chief hazards are those attending the use of solvents. The chief solvents so employed are naphtha, Stoddard's solvent and carbon tetrachloride. A wide variety of other substances are in infrequent use. All the solvents specified by name may irritate the skin locally, may enter the body through inhalation or may be taken into the body through the skin. In the manufacture of felt hats, mercury is still in some use as the carotting agent. The hazard of mercury poisoning is definite in some hat manufacturing establishments. Quite remotely, it is possible that in hat cleaning work sufficient mercury might be removed from the felt fibers to produce mercury poisoning. Even more remote is a possibility that arsenic poisoning might arise from the occasional use of that substance in the carotting fluid. In some gas burners may give rise to sufficient carbon monoxide to bring about injury to those exposed.

## THERAPY OF CORONARY THROMBOSIS

To the Editor—In three cases clinically diagnosed as coronary occlusion on the first visit the patients were given morphine sulphate hypodermically, amyl nitrite by inhalation and caffeine sodobenzoate hypodermically and then one or two tablets of nitroglycerin compound (DaCosta). Upon in each case the patients died in from three to five minutes after receiving the nitroglycerin compound tablets. Is it contraindicated to give glyceryl trinitrate in a dosage of 1/400 grain (0.6 mg) in a case of coronary occlusion? In the cases mentioned do you believe that the administration of the nitroglycerin (glyceryl trinitrate) compound tablets was responsible for the sudden deaths? Kindly omit name  
MD California

ANSWER—It is contraindicated to give either glyceryl trinitrate or amyl nitrite in cases of coronary thrombosis and especially in cases in which the blood pressure has fallen at the onset. Alarming syncope and symptoms occur at times even in apparently normal individuals. There is no certainty that the administration of glyceryl trinitrate in caused the death of these patients. It is frequently used in such cases with safety, but it is always inadvisable and dangerous.

## TREATMENT OF SPIDER BURST VARICOSE VEINS

To the Editor—Can you outline a treatment for small spider burst or skyrocket varicose veins in a young woman who seeks relief because of their unsightly appearance on her legs when exposed on the beach? She has had no palpable enlarged or dilated varicose veins such as are suitable for injection. There is no edema present and she has never had phlebitis.  
WILLIS P. BAKER MD Santa Ana Calif

ANSWER—The treatment for a spider burst is difficult and usually unsatisfactory. At times, after distending the veins with the help of a tourniquet, one can find a larger venous pocket, the so-called key-vein, which when obliterated will cause a shrinkage and fading of the small cutaneous varices. Another method is to take a fine intestinal needle, dip it into a 5 per cent solution of sodium morrhuate or 50 per cent dextrose solution, and puncture the individual branches of the spider burst. This may require a great many punctures and

turbance of endocrine function. A metabolism test must be made by an expert to help solve the problem. The anemia found so often in blood donors can easily be diagnosed. One may often relieve the condition in cases in which pamp-taking examination fails to reveal the cause by advising an outdoor life with plenty of sunshine and the internal administration of tablets of anterior pituitary substance. Large doses, as much as 5 Gm (80 grains) a day for several months are given. Of late successful results have been reported with the hypodermic administration of anterior pituitary-like principle from pregnancy urine three times a week for several weeks. As there is possibility of producing excessive hypertrophy of the prostate with the latter treatment is reported in monkeys by Geschickter, Lewis and Hartman, this should be employed with care.

## APPLE DIET FOR COLITIS AND INFANT DIARRHEA

To the Editor—Recently I have been hearing of the feeding of scraped ripe apples for colitis and infantile diarrhea. Would you please publish your opinion of the value of this food or treatment in reference to its corrective use in children's diseases.  
R. C. HUNTER MD Wapakoneta Ohio

ANSWER—The apple treatment consists of a diet of only raw scraped apple. Completely ripe and mellow fruit should be used. From one to four tablespoonfuls is fed every hour or two for forty-eight hours. The amount given varies with the age of the patient. Nothing but water should be given besides the pureed apple. After the forty-eight hours, three meals are resumed as follows. In the morning, farina (cooked for one hour in water), toast and cocoa (made with water). At noon soup with rice, scraped beef and toast (cooked cottage cheese, toast, ripe banana puree and cocoa made with water). After forty-eight hours boiled milk is added to the vegetable puree and finally fruit in small amounts. The diet should not be used for infants. Formed stools usually appear within forty-eight hours after the treatment is instituted. (The method is described by Birnberg T. L. Raw Apple Diet in the Treatment of Diarrheal Conditions in Children. Am J Dis Child 45:18 [Jan] 1933).

## SPREAD OF SCARLET FEVER

To the Editor—Reference is made to the spread of scarlet fever and that part of your reply (THE JOURNAL July 21, p. 208). It has been shown that the air in a room occupied by a scarlet fever patient may be contaminated and articles in the room may likewise be contaminated. Will you please cite me a single instance by a reliable authority in which the air of a room has acted as a mode of conveyance in any of the communicable diseases? Apart from the handkerchief secretions and drinking glass how could contamination take place by articles in the room?  
HENRY FARRELL MD McCook Neb

ANSWER—Scarlet fever belongs to the group of air borne diseases. Contamination of air in the immediate vicinity of the patient may be demonstrated by exposure of blood agar plates. Weaver and Murdoch (THE JOURNAL Dec 21, 1919, p. 1921) and Matousek (THE JOURNAL, May 28, 1921, p. 1490) reported contamination of door knobs and similar objects as well as contamination of the hands and masks of attendants.

## SYPHILIS OF NERVOUS SYSTEM

To the Editor—I have a patient who contracted syphilis about twenty years ago. He had his blood examined several times and then was told that it was safe for him to get married which he did. About two years later his wife gave birth to a perfectly normal baby girl. About ten years ago he came to me suffering with symptoms of appendicitis. I tested him out thoroughly and found a 4 plus Wassermann reaction and put him on syphilitic treatment for at least six months and he improved gradually. He then moved to another town and took treatment for some time from another physician. Later he developed a type of grandeur imagined he had all kinds of money and commenced to write checks accordingly but was soon stopped. He was sent to a sanatorium and proved fatal. Then they put him on trypanamide weekly. Now he seems to be perfectly normal except for complaints continually of a creeping sensation across his forehead from temple to temple and at night he has to tie his head up in order to sleep. I would appreciate any suggestions you may offer.  
MD

ANSWER—In the first place it is suggested that the patient should keep under treatment with trypanamide unless there is some definite contraindication until the cerebrospinal fluid tests are all negative. It is not possible to offer a diagnosis as to the cause of the creeping sensations in the forehead on the meager data furnished. Without a diagnosis it is not possible to suggest treatment.

may produce hematomas, which may leave a brownish discoloration. Another possibility is to take a surgical diathermy current and with a very fine tip coagulate the blood in several of the larger varicosities.

Of all these suggestions the only satisfactory method is the injection of the feeder vein. Even this method, however, will not give a cosmetic result.

#### COPPER SULPHATE IN SWIMMING POOLS

*To the Editor*—In a local salt water swimming tank copper sulphate is used in the proportion of 1 160 000 to retard marine growth. Would 1 80 000 be injurious to the eyes or skin or dangerous if some of it should be accidentally swallowed? Please omit my name.

M D California

**ANSWER**—The amount of copper sulphate stated is far greater than that usually required to prevent organic growth in swimming pools. However, most of the data available apply to fresh water tanks. If the water is alkaline, much of the copper would be precipitated and larger doses would be necessary under these conditions. The dosage usually employed in fresh water tanks and reservoirs is in the neighborhood of 1 part per million. The dosage must be varied with the type of growth in the tank, since some organisms are far more sensitive than others to copper salt. It is doubtful whether occasional swallowing of a small amount of water containing 1 part of copper sulphate in 80,000 would be in any way dangerous. The government standard of 0.2 part of copper per million would not be applicable to swimming pool conditions because of the relatively small amount of swimming pool water consumed.

#### PHYSIOLOGIC SOLUTION OF SODIUM CHLORIDE INTRAVENOUSLY IN NEPHRITIS

*To the Editor*—It is I believe fairly well agreed that sodium chloride should not be allowed patients who have nephritis. For a patient with uremia, unable to take much fluid by mouth with no evidence of edema what is the consensus regarding the giving of say 2 000 or 3 000 cc of physiologic solution of sodium chloride intravenously? Would this amount of sodium chloride cause further damage to the kidneys? Would it be preferable to give 5 per cent dextrose? Please omit name.

M D, Mississippi

**ANSWER**—There is hardly a consensus on this subject. The objections to giving physiologic solution of sodium chloride to a nephritic patient without evidence of salt and water retention are more theoretical than real. However, since the difference in opinion does exist and since the object is to administer needed fluids, it would be preferable to give dextrose solution.

#### TRACING SCARLET FEVER CARRIERS

*To the Editor*—In the July 21 issue of *THE JOURNAL* page 208 there is a query concerning the spread and control of scarlet fever. You recommend a quarantine of the patient until cultures on blood agar plates are negative for scarlet fever streptococci. Kindly give the technique for culture and identification of these organisms. Do you consider this procedure of value in tracing scarlet fever carriers? Please omit name and address.

M D New York

**ANSWER**—Cultures from the nose and throat are made on freshly prepared blood agar plates. The plates are incubated over night and examined for the presence of hemolytic streptococci. If cultures continue to show the presence of hemolytic streptococci over a prolonged period, a specificity test may be made by testing a sterile filtrate from a broth culture of the organism for the presence of scarlet fever toxin.

#### SOLUTION OF ARSENOUS AND MERCURIC IODIDE FOR WARTS

*To the Editor*—I have been told that a dermatologist in a southern state uses Donovan's solution internally for the treatment of warts claiming that he has marked success with this treatment. Kindly tell me whether there is any scientific basis for such a method or if there is any reliable literature on the subject.

HENRI L DUVRIES M D Chicago

**ANSWER**—The beneficial use of Donovan's solution (solution of arsenous and mercuric iodide) is dependent on the contained arsenic and mercury. Arsenic and mercury, respectively, have been used for a long time in the treatment of verrucae. Their use, however, is empirical, and there has been considerable discussion as to the role of these drugs in the successful treatment of warts.

More recently the question of sulpharsphenamine in the treatment of warts has been discussed by Allington (*Arch Dermat & Syph* 29 687 [May] 1934), and he concludes that, in the treatment of warts sulpharsphenamine injected intramuscularly appears to have little if any advantage over distilled water given in like manner.

#### CORONARY THROMBOSIS

*To the Editor*—What is the ultimate prognosis for one (a man aged 44) recovering from a coronary thrombosis? Can it ever be said that he is entirely well and will he ever be able to do arduous work and heavy lifting again? Please do not publish name.

M D, District of Columbia

**ANSWER**—A definite prognosis cannot possibly be made. There is no accurate method of evaluating the damage done, and it is necessary to keep well within the limits of safety. A great many cases make what is apparently a complete recovery. It is possible that a patient could again do arduous work after a coronary thrombosis, but it is improbable, and he should by no means be allowed to attempt it. Activity should be increased only by small increments after a long period of complete rest and the extent of his future activities judged by his response.

Much of the prognosis will depend on the presence or absence of some underlying cardiac or vascular pathologic change.

#### TREATMENT OF LEAKAGE OF NEOARSPHENAMINE INTO TISSUES

*To the Editor*—While neoarsphenamine was being injected intravenously a little of the solution escaped into the tissues around the vein. It was only a few drops as the patient immediately complained of pain and burning. It made quite an inflammation and considerable tenderness over a period of two weeks but is now better. Do you know of anything that may be injected into the area immediately to modify the severity of the inflammation something like sterile water or, better something that will make a chemical change?

JOHN RICHARD BOOTH, M D Oakland Calif

**ANSWER**—The immediate injection of from 20 to 30 cc of physiologic solution of sodium chloride, preferably with the addition of 0.5 per cent of procaine hydrochloride, should give relief. It is well to have this solution always ready at hand when injecting irritative solutions intravenously so that it may be injected immediately after the paravenous leakage while the needle is still in place.

#### TREATMENT OF GLUTEAL HERPES

*To the Editor*—What remedies used empirically can you recommend for herpes of the gluteal region. So far as can be ascertained there are no pelvic or other pathologic changes except chronic recurrent purulent proctitis. All the sinuses have been operated on. The patient is a woman aged 35. Please omit name.

M D, Chicago

**ANSWER**—In cases in which there is little or no pain or itching, protection by the liberal application of a dusting powder, such as thymol iodide, suffices, which is then covered with several layers of gauze kept in place by adhesive plaster. If there is much itching and burning, sponging several times a day with alcohol gives relief, which may be accentuated by the addition of 1 or 2 per cent of resorcinol or of menthol. A dusting powder of talcum with 3 per cent of camphor may be used in the intervals between the sponging, and the lesion covered with liberal dressing of gauze or cotton. When pain is a prominent symptom, the internal administration of analgesics, such as acetylsalicylic acid, amidopyrine or even morphine, is indicated.

#### TERMINAL EVENT IN AORTIC REGURGITATION

*To the Editor*—What is the final event in aortic regurgitation? Does one get edema of the extremities and pulmonary congestion? Is it common to get a gallop rhythm? The literature that I have read on these conditions is usually under the heading of mitral stenosis or myocarditis. Please omit name.

M D South Carolina

**ANSWER**—There is no characteristic terminal event in aortic regurgitation. There are almost always other factors that are valent, as valvular lesions elsewhere, myocardial changes, vascular disease of the coronaries or the aorta, and disease of the kidneys. A case may show edema of the extremities and pulmonary congestion during its course or as a terminal event.

#### RETINITIS PIGMENTOSA

*To the Editor*—I am seeking information regarding the treatment of retinitis pigmentosa by the method devised by Prof. Joseph Imre of Budapest. If you can send me any information regarding this it will be greatly appreciated.

WILLIAM J HARRINGTON Appleton, Wis

**ANSWER**—The method proposed by Imre was the inhalation of amyl nitrite every second day for several months or even longer. He published this in the proceedings of the Deutsche Ophthalmologische Gesellschaft forty-eighth meeting, 1930 page 279. The details of three cases that showed marked improvement in vision were recited and a cautious statement as to the therapeutic value of this method was made.

## INDICATIONS FOR INSULIN IN DIABETES

*To the Editor*—What is the consensus in regard to the use of insulin? Would it be advisable for a sugar free diabetic patient (under restricted diet) to take a small dose in anticipation of a good meal once in a while? If it is true that a more liberal diet is beneficial why not give insulin in all cases, whether mild or severe? Please omit name

M D Massachusetts

**ANSWER**—It is not considered advisable for a diabetic patient sugar free on a restricted diet without insulin, to break that diet. It is true that he may counteract the harmful effect of breaking the diet by taking insulin, but this is certainly not good treatment. The diet should be made adequate in every nutritional respect, and if the patient cannot tolerate it he should use insulin. On the other hand, adequately nourishing diets can be arranged that will permit many patients with mild diabetes to remain sugar free without insulin. The advantage in this is principally in economy, although many authorities in diabetes believe that moderate restriction of carbohydrates and careful limitation of calories to actual requirements is desirable in most cases of diabetes whether insulin is taken or not.

## PROGRESSIVE MYOPIA

*To the Editor*—Is there any approved surgical treatment of progressive myopia other than enucleation of the crystalline lens? Please omit name

M D Pennsylvania

**ANSWER**—No

## RUPTURED EARDRUM AND TELEPHONE RECEIVER VIBRATION

*To the Editor*—In reply to the query by Dr. Milton Wolpert of Chester W. Va. (THE JOURNAL July 28 p. 282) I would like to relate my own experience with ruptured eardrum due to sudden excessive increase in telephone receiver diaphragm vibration. In 1925 while intern-ing at the Metropolitan Hospital I had occasion to use the telephone booth at the staff house. After I had dropped my coin and while I was speaking to the operator there was a sudden terrific crack (as it seemed to me) she connected my wire with the proper central station. I reeled half way round in the booth, my brain in a whirl. I fell against the door somewhat dizzy. My heart palpitated to a marked degree and I walked out of the telephone booth and asked a doctor friend to examine my ear explaining to several present what had occurred. I was told what I already knew—that there was a rupture of the right eardrum and a drop of blood on the membrane itself. I had some difficulty in hearing for two or three days and forgot about it (using no treatment but a sterile pledget of cotton in the canal). Previously in my boxing matches at college and several months before at the same hospital I had occasion to experience ruptured eardrum when in one case a student landed with an open palm on my left ear. I experienced the same effect. Examination revealed a ruptured drum. The same eardrum was ruptured in a second boxing match when a doctor at the hospital (the doctor weighing 200 pounds and 6 feet tall) landed with an open palm on my much abused ear with exactly the same series of symptoms and signs. I mention these friendly encounters only to suggest that I could recognize a ruptured drum even without otoscopic examination. I intended I might add to institute proceedings against the telephone company had any sort of complication set in. It is surprising the great sudden power set up in that auditory canal if the receiver is pressed tightly to the ear—which I never do any more and which I advise every one not to do.

MICHAEL WISHEWGRAD M D New York

## MUSCLE CRAMPS DURING SLEEP

*To the Editor*—In Queries and Minor Notes in THE JOURNAL August 18 is a communication from a New York physician on muscle cramps during sleep. During years of practice especially with diabetic patients who are very prone to such cramps I have found an almost infallibly successful treatment. Dilute hydrochloric acid from 10 to 15 drops in water with each meal will completely relieve most cases within a day or two. When intestinal putrefaction is present to augment the alkalosis by absorption of the alkaline anuresis kaolin therapy is advisable in addition to the acid. The kaolin is best given finely suspended in syrup one fourth ounce morning and evening.

## DOWELL TEST OF PREGNANCY

*To the Editor*—M D Pennsylvania (THE JOURNAL August 18 p. 510) rightly questions Dr. Dowell for exact details of his test. May I call the attention of both to the fact that the test is neither original nor reliable and refer them to an article on the same subject by the writer and printed in the *American Journal of Surgery* (8:1271 [June] 1930). In this article I refer to the originators of the test Drs. Porges and Pollatschek of Vienna and claim no originality whatever. However I present a moderate series of cases by this test and prove statistically that it is neither definite nor reliable. In addition a personal communication from the authors is brought out in which their final results do not coincide with their glowing praise in the original paper. The conclusions of a Dr. Deutsch of Vienna also coincide with mine as brought out in the paper.

## New York January-February Examination

Mr Herbert J Hamilton, chief, Professional Examinations Bureau, reports the written examination held by the New York State Board of Medical Examiners in Albany, Buffalo, New York and Syracuse, Jan 29-Feb 1, 1934. The examination covered 9 subjects. One hundred and ninety candidates were examined, 146 of whom passed and 44 failed. The following schools were represented:

School	PASSED	Year Grad (1933)	Number Passed
University of Arkansas School of Medicine		(1933)	1
Yale University School of Medicine		(1931) (1932) 3	4
George Washington University School of Medicine		(1933) 4	4
Georgetown Univ School of Med		(1930), (1932) 4	6
Emory University School of Medicine		(1931)	1
Loyola University School of Medicine		(1930) (1933)	2
Rush Medical College		(1933) 2	2
University of Louisville School of Medicine		(1931), (1932)	2

# Book Notices

**A Practical Treatise on Diseases of the Skin for the Use of Students and Practitioners** By Oliver S. Ormsby, M.D. Clinical Professor and Chairman of the Department of Dermatology, Rush Medical College of the University of Chicago. With Revision of the Histopathology in This Edition By Clark Wylie Finnerud, B.S., M.D. Assistant Clinical Professor of Dermatology, Rush Medical College of the University of Chicago. Fourth edition. Cloth. Price \$11.50. Pp. 1288 with 622 illustrations. Philadelphia: Lea C. Febiger, 1934.

Recognized as one of the leading textbooks in the field of dermatology, this work represents one of the most complete considerations of the subject anywhere available. Its history goes back many years. In its preparation, all the dermatologic literature is carefully reviewed. In the present edition thirty-six new diseases are described. The accounts of twenty diseases are rewritten and the entire book is reconstructed. One hundred and twenty-four new pictures have been added, since it is recognized that illustration is a vital accessory to any dermatologic publication. This volume is scientifically constructed for the teaching of dermatology, setting forth first a working knowledge of the microscopic anatomy and physiology of the skin and following with a general discussion of symptomatology, etiology, diagnosis and treatment. Then comes the consideration of individual diseases of the skin classified according to both pathologic conditions and etiologic considerations. These are the classifications suggested by Hebra and modified by many others. This textbook has made itself a distinct place in its field. It offers particularly valuable material on all distinctly dermatologic subjects. For occasional conditions with dermatologic manifestations but of a more general character it sometimes is not quite satisfactory. Thus in the consideration of Vincent's disease there is no mention in treatment of the use of sodium perborate and there is the suggestion that arsenphenamine be employed both locally and by injection. Although observers of diseases of the skin have begun to pay some attention to vitaminic deficiencies in relationship to skin disorders the word vitamin is not found in the index. The volume is particularly adequate in its consideration of syphilis and the dermatologic manifestations of that disorder. The choice of the illustrations is for the most part excellent although there are three pictures of vitiligo when one would fully suffice. The volume constitutes altogether one of the best reviews of dermatology available particularly from the point of view of the histopathology of the skin. It should be available to every physician who even attempts to diagnose or treat dermatologic conditions.

**Diseases Peculiar to Civilized Man. Clinical Management and Surgical Treatment.** By George Crile, M.D. Edited by Amy Rowland. Cloth. Price \$5. Pp. 427 with 41 illustrations. New York: The Macmillan Company, 1934.

Among the diseases which occur particularly in civilized human beings and which apparently are not found in savages or in the lower animals are peptic ulcer, hyperthyroidism and neurocirculatory asthenia. In considering their causation, Dr Crile traces the development of the human brain from the lowest form to the highest and elucidates his belief that the diseases mentioned belong to the group of kinetic diseases, which are diseases of pathologic physiology bred in our phylogeny, in which there is a sustained abnormally high activity of the entire brain and suprarenal sympathetic system. He considers the development of the suprarenal glands and the suprarenal sympathetic system and then takes up each of the diseases mentioned, supplying case histories and indicating the value of suprarenal denervation as a means of control. There is also a section devoted to epilepsy and diabetes, including case histories of the method as applied to these conditions, followed further by a discussion of combinations and by a discussion of the psychoneuroses and hypertension. The first suprarenalectomy was performed in October 1913. It was found later that suprarenalectomy did not answer the situation, so that the new operation of suprarenal denervation was developed. The author reports operations performed in seventy-six cases of true neurocirculatory asthenia with improvement or cure in 94 per cent, seventy-nine cases of hyperthyroidism with cure in

93.7 per cent, and thirty-seven cases of peptic ulcer with improvement or cure in 96.4 per cent. He feels that this introduces a new principle into medical thought and that the method should have extensive and careful consideration by the medical profession.

**Le sérum normal. Récolte et caractères physiques.** Par Denis Brocq, Roussel et Gaston Roussel. Paper. Price 75 francs. Pp. 363. Paris: Masson & Co., 1934.

This is the first volume of a series on normal serum. The second volume will treat of the physiologic characteristics of serum and subsequent ones of the chemical. Much confusion has been caused because in the past certain authors have considered the words plasma and serum as equivalent. In this work the word serum is applied only to the fluid that exudes naturally after the clotting of the blood. And normal serum is the serum of an animal in good physiologic equilibrium not subjected to immunizing injections. The present volume deals with the collection and physical characters of normal serum. The collection of serum from the horse, man and other species, and its conservation, aging and putrefaction are described in detail. Then follow chapters on the physical properties—density, osmotic pressure, electrical conductivity, dialysis, ultrafiltration, electrolysis, surface viscosity, refractometric index, rotatory power, color, spectroscopy. Each chapter is complete by itself giving the technical methods of study and the results obtained in recent investigations with due regard to variations, physiologic as well as experimental and pathologic. Each chapter is provided with a bibliography, which goes to April 1, 1933. The references number 1,321 in all and occupy fifty-six pages. To the investigator the bibliography will be of much value. There can be no question that this is the beginning of a great work on serum of distinguished scholarship.

**Charles Oliver Probst. A Pioneer Public Health Administrator in Ohio.** Edited by Robert C. Paterson, F.H.D., Executive Secretary, Ohio Public Health Association. Boards. Pp. 70. Columbus: Ohio Public Health Association, 1934.

The edition of this book, privately printed, is limited to 300 copies. Whether or not one knew the physician in whose memory it is issued, whether or not one is interested in Ohio, it is an interesting and worth-while volume, showing as it does the typical early history of state health departments in the United States. Conceived as so many others were in the minds of public spirited physicians and laymen, growing from tiny nuclei to great organizations in many instances, the health departments stand as the visible evidences of the early efforts of medical societies and lay groups to meet pressing problems of public health. Close cooperation between physicians and policy, as reflected in the tributes paid to him at the memorial meeting held at Mount Vernon, Ohio, under the joint auspices of the Ohio State Sanatorium and the Ohio Public Health Association, both of which he was instrumental in founding. The state of Ohio has built a splendid health program on the beginnings which Dr Probst struggled to achieve. The memorial volume outlines the achievements of Dr Probst in public health work and his character as a physician, a sanitarian and a citizen. The bibliography of his writings indicates a wide interest in medical and public health matters, as well as literary appreciation.

**Praktikum der wichtigsten Infektionskrankheiten.** Von Prof. Dr. C. Hegler, Direktor des allgemeinen Krankenhauses St. Georg in Hamburg. Paper. Price 4.50 marks. Pp. 186. Leipzig: Georg Thieme, 1934.

In the foreword the author states that he presents a condensed book for the practitioner. He makes no pretense of going into great detail with the diseases discussed but hopes that the subject matter will stimulate greater study. The views expressed are based almost wholly on personal experience. Among the infectious diseases, nearly all the common ones as well as those less frequently encountered are referred to. Limited mention in most instances, is made of diseases carried or transmitted by animals. Some of the important food poisonings are mentioned. The author seems to emphasize the importance of the Diazo reaction in the exanthematous diseases and recommends numerous proprietary remedies in the treatment

## BOOK NOTICES

JOUR A V A  
SEPT 29 1934

**A Textbook of the Practice of Medicine** By Various Authors Edited by Frederick W Irie MD FRCS Consulting Physician to the Royal Northern Hospital London Fourth edition Cloth Price 36s 1p 1935 with Illustrations New York & London Oxford University Press

This leading British composite textbook of the practice of medicine is comprehensive, containing almost 2000 pages printed on thin paper. The first edition appeared in September 1922, and there were five printings. The second edition was published in 1926 with two printings and the third edition in 1929 with three printings. The present edition has been thoroughly revised and brought up to date, containing new articles on many subjects. The list of contributors to the volume includes twenty-seven British physicians whose names are notable in British medical periodical literature. Thus the vitamins are discussed by Plummer syphilis by Harrison, and the gastro-intestinal diseases by Hutchison and Hurst. The volume affords an adequate reflection of British methods of practice.

**Woman as a Sexual Criminal** By Doctor Erich Wulffen Translated into English by David Berger M A Cloth Price \$6 Pp 528 with 16 Illustrations New York American Ethnological Press 1934

This translation from the German is obviously printed to take advantage of the current especially heightened interest in sex matters. The publishers have circulated the various ways in which women have run afoul of the law in sex satisfactions. The book is not especially well printed nor is it in any sense of the word a modern consideration of the subject. Most of the case reports seem to be taken from records of fifty and a hundred years ago.

**The Span of Life as Influenced by the Heart the Kidneys and the Blood Vessels** By Franklin R Nuzum BS MD FACP Medical Director Santa Barbara Cottage Hospital Cloth Price \$2 Pp 108 with 9 Illustrations Springfield & Baltimore Charles C Thomas 1933

Dr Nuzum prepared these essays as a series of informal talks to the public making understandable the relationships of the heart, the kidneys and the blood vessels and indicating their influence in determining the length of human life. Whereas the vast majority of deaths in a previous generation were due to infectious diseases, the great number of deaths today are due to breakdown of the heart the kidneys and the circulation. The greatest opportunity to increase the length of life still further depends on an understanding of the work of these organs and on the cooperation of the patient with the doctor in the hygiene of these organs. Dr Nuzum has written in a manner which any intelligent reader can understand. His work should be exceedingly useful for reference by physicians to patients who need this advice in their cooperation.

**The Cyclopedia of Medicine** George Morris Piersol BS MD Editor In Chief and Edward L Boritz AB MD Assistant Editor Chief Associate Editors W Wayne Babcock AM MD Conrad Berens MD P Brooke Bland MD Francis L Lederer BS MD and A Graeme Mitchell MD Volumes VIII and IX LAR 1 R 1 Fabricoid Price \$120 per set of 12 volumes and Index Pp 1083 1166 with Illustrations Philadelphia F A Davis Company 1933 1934

Volumes VIII and IX of this encyclopedia cover medical subjects alphabetically from disorders of the larynx to potasium. The articles represent the work of many leading contributors to medical periodical literature. There is occasionally unevenness in the presentation but on the whole the material is sound and adequate. There are some fine articles by Chevalier Jackson dealing with the lungs by Chenev on the gallbladder, and by Boothby, Heiser, Mann and many other distinguished workers in the medical field. The editors have chosen extraordinarily well in their contributors, and the books may be generally recommended as competent and authoritative.

**Medicación local pulmonar por vía intratraqueal** Por el Dr Vicente de Iablo médico adscripto al Dispensario Nacional Antituberculoso (Zona Norte) Iaper Pp 57 with 10 Illustrations Buenos Aires Anlelo Lopez 1933

In this book the author describes his modifications in the technic and instruments used by Garcia Vicente of Madrid for local medication of the bronchi and lungs by the transglottic route. After working with Garcia Vicente he was much impressed with the value of the latter's methods and introduced

of various infections. In regard to scarlet fever the opinion is set forth that the cause has not yet been definitely established also that the frequency and severity of complications are little influenced by scarlet fever serum. There is nothing new in this book that might merit more favorable comment if it were not so lacking in many important details that are really desirable for the practitioner. In most respects statements are much too indefinite to be of practical value. However, if the author's main objective in writing the book was merely brevity, he has succeeded admirably. The contents of the volume amount to little more than a medical dictionary of the subjects mentioned. It is particularly disappointing in view of the author's citation respecting his experience. In striving for brevity an attempt has been made to crowd too large a field into too small a space.

**Rhythm of Life A Guide to Sexual Harmony for Women** By Solfe Lazarsfeld Translated by Karsten and E. Pelham Slapeltz MD Cloth Price \$5 Pp 329 with 12 Illustrations New York Greenberg 1934

Recent years have seen the publication of a considerable number of works attempting to educate the public as to proper sex relations in life. This volume by a woman physician is addressed primarily to women. It discusses the development of marriage among the various peoples of the world. It then outlines the mechanism of sexual intercourse. It considers the position which woman occupies in modern society and calls attention to a rhythm of sex interest which apparently is to be followed carefully by those who wish to make the most of the physical side of married life. The author is inclined to recommend training in eroticism as a concomitant of a successful sex career. The concluding chapters of the book deal with cases from practice and the author's method of handling them. Presumably in an effort to make the book more interesting to its readers, the publisher has supplied a number of illustrations which run the gamut from Rodin sculptures through pictures of various chastity girdles to an apotheosis with a picture of Mae West. While the book is of interest its appeal to sensationalism so vulgarizes its content that one is hardly inclined to recommend it to the general reader.

**A Short History of Some Common Diseases** By Divers Authors Edited by W R Burt MRC S L R C P Hon Secretary Section of History of Medicine Centenary Meeting British Medical Association Cloth Price \$3 50 Pp 211 New York & London Oxford University Press 1934

Here under one cover are assembled numerous references to a vast amount of literature presenting the progress medicine has made in controlling various diseases. A considerable number of competent British authors have combined in the development of the book. They not only indicate the names of those who have made studies but also the origins of words used in connection with various diseases the dates of great epidemics and much miscellaneous information. Furthermore short bibliographies are provided for those who wish to read of medical knowledge. The history of appendicitis is one of the most interesting chapters in the book. In this chapter adequate attention is paid to the contribution of Fitz. The author relates the popularity of appendicitis as a diagnosis in England to the operation performed on King Edward VII by Sir Frederick Treves. The volume is a most useful work of reference and also in many parts exceedingly readable.

**Il cancro del retto** Da Vittorio Pettinari aiuto e libero docente Istituto di patologia chirurgica della R Università di Milano Paper Price 30 lire Pp 225 with 121 Illustrations Bologna Lichio Capelli 1933

This monograph on cancer of the rectum considers malignant conditions of the rectum and rectosigmoid from the clinical as well as the histologic standpoint. Excellent statistics are presented showing the mortality and the clinical results of the various operative procedures, which are clearly and concisely described. The histologic sections collected are illuminating and a study of them can be helpful to maintain one's capacity to interpret the microscopic appearance of malignant growths. With admirable erudition the author has done justice to all the main contributors to the clinical surgery of this important subject. A careful perusal of the monograph will reorganize one's knowledge of the subject and make possible a systematic comprehension of the recent advances that have been made.

them in Argentina. However, he felt that the technic and instruments were still not perfect and proceeded to modify them. For example, he changed to a more obtuse angle the tip of the syringe used for transglottic intratracheal injection, as well as the forceps used for introducing catheters. He also replaced the cone-shaped end of the tip of the syringe with a small olive perforated on all sides so as to permit more equal distribution of the medicament over the tracheal mucosa as soon as it is injected. De Pablo advocates the use of semirigid catheters for aspiration of the bronchi, which he regards as preferable, in some cases, to lavage. In conclusion he states that, since it is now possible to reach easily the exact area of lung that is diseased, aspirate it and convey medicaments directly to it, the discovery has been made of what will prove to be the most important avenue of approach for the treatment of pulmonary diseases. The book contains a preface by Garcia Vicente and an ample bibliography.

**Gesetz zur Verhütung erbkrankten Nachwuchses vom 14. Juli 1933 mit Auszug aus dem Gesetz gegen gefährliche Gewohnheitsverbrecher und über Maßregeln der Sicherung und Besserung vom 24. Nov. 1933.** Bearbeitet und erläutert von Dr. med. Arthur Gütt, Ministerialdirektor im Reichsministerium des Innern, Dr. med. Ernst Rüdin, o. o. Professor für Psychiatrie an der Universität in München, und Dr. jur. Falk Rutke, Geschäftsführer des Reichsausschusses für Volksgesundheitssdienst beim Reichsministerium des Innern. Mit Beiträgen Die Eingriffe zur Unfruchtbarmachung des Mannes und zur Eulimnung von Gehirnrat Prof. Dr. med. Erich Lexer, München. Die Eingriffe zur Unfruchtbarmachung der Frau. Von Gehirnrat Prof. Dr. med. Albert Doderlein, München. Paper. Price 6 marks. Pp. 272 with 15 illustrations. Munich: J. F. Lehmanns Verlag, 1934.

This book lists and describes the recently enacted laws in Germany for the prevention of hereditary diseases. An introductory chapter deals with the family distribution of several supposedly inherited defects. The eight conditions for which sterilization is now mandatory—born feeble-mindedness, schizophrenia, circular insanity, hereditary epilepsy, Huntington's chorea, hereditary blindness, hereditary deafness, and hereditary bodily deformities—and the further condition of "severe alcoholism" are discussed in detail. It is interesting to note that severe alcoholism is not considered hereditary but that incurable alcohol craving is believed to rest on a constitutional hereditary psychopathic basis and hence children of these individuals are not to be desired. A chapter on the technic of male sterilization by Lever of Munich and one on the technic for females by Doderlein are added. Whatever one may think of the basis for these enactments in Germany, this book is and will remain an interesting document.

**Constitution and Health.** By Raymond Pearl, Professor of Biology in the Johns Hopkins University, Baltimore. Isclic Miniatures General Series No. 60. Cloth. Price 2/6. Pp. 97 with 9 illustrations. New York: Barnes & Noble Inc., London: Hegan Paul French Trubner & Co. Ltd., 1933.

Dr. Pearl offers here an expansion of a lecture given in 1933 at the Army Medical Center. In this statement Dr. Pearl indicates the present point of view of the relationship of constitution to health. He points out that the constitution of the individual may change during life, listing some of the studies that have been made on the relationship of body form to health and disease. His conclusion is rather striking—namely, that a careful statistical examination of rather accurate, if not very extensive, material does not yield evidence of any very marked or striking association between bodily habitus and general health. He points out that we are only at the beginning of any real knowledge in this field and that many vast statistical studies are necessary before any definite conclusions can be drawn.

**Milton's Blindness.** By Eleanor Gertrude Brown. Cloth. Price \$2.50. Pp. 167. New York: Columbia University Press, 1934.

The poet Milton, like many others afflicted by physical deformities, had a life much modified by his handicap. The author of this book has herself been blind almost from early youth and thus writes with a special sentiment. Portions of the book consider the cause of Milton's blindness, his own references to it, the reflections of his character in his poetry, and a final chapter entitled "Milton's Eyes Take a Holiday." This discusses the effects of the blindness, the autographs of Milton, praise and dispraise of his work, and similar topics. A good bibliography makes the book complete.

**Stand Up and Slim Down. Being Restoration Exercises for Women With Chapter on Food Selection in Constipation and Obesity.** By Mrs. Etlle A. Hornbrook (Etlle Rout). Prefaces by Sir Arthur Keith, F.R.S., M.D., F.R.C.S., and Dr. A. C. Haddon, M.A., Sc.D., F.R.S. Second edition. Cloth. Price \$1.95. Pp. 167 with 16 illustrations. Garden City: Doubleday Doran & Company, Inc., 1934.

The author has developed a series of exercises supposed to aid women in getting rid of protuberant buttocks and an over-stuffed waistline. The book provides a series of exercises said to be useful for this purpose and also some diets said to be valuable for overcoming constipation as well as obesity. The author is especially inclined to recommend the dances much used by the savages in their religious and social efforts, commonly called the "danse du ventre" or more vulgarly known as the "belly dance."

**L'immunité par mécanisme physico-chimique.** Par R. Dujarric de la Rivière. Préface du Professeur d'Arsonval. Paper. Price 18 francs. Pp. 73 with 2 illustrations. Paris: Masson & Cie, 1934.

The author summarizes here the results, previously published of investigations by himself and his associates on the role of physicochemical factors in the action of certain disinfectants, on the flocculation of antimeningococcus serum, and on the adsorption of certain substances by the red corpuscles of the blood. The demonstration of the adsorption and transport by the red corpuscles of toxins, anatoxins (toxoids) and certain antisyphilitic medicaments is especially noteworthy.

**The Fundamentals of Personal Hygiene Including Their Practical Application to Healthful Living.** By Walter W. Krueger, Ph.D., Instructor in the Grand Rapids Junior College. Cloth. Price \$1.75. Pp. 291 with 60 illustrations. Philadelphia & London: W. B. Saunders Company, 1932.

This book is planned primarily for elementary students with a view to aiding them to a rational health program for daily living. It is an easily readable, pleasant textbook on personal hygiene, simply prepared, nicely illustrated and altogether sound. The author avoids faddism and follies.

## Medicolegal

**Validity of Regulation of Board of Health Excluding Unvaccinated Children from School.**—City health officers in Indiana are authorized by Burns' Indiana Statutes Annotated, 1926, section 8168, "to establish quarantines and in connection therewith, to order what is reasonable and necessary for the prevention and suppression of disease, to close schools and churches and forbid public gatherings in order to prevent and stay epidemics, and in all reasonable and necessary ways to protect the public health." Further, an Indianapolis ordinance requires the city board of health whenever there is an epidemic of smallpox, or danger thereof, "to take measures and to do and order . . . such acts for the preservation and protection of the public health . . . as said Board may in good faith declare the public health and safety to demand," and to publish in the newspapers a notice of such epidemic or threatened epidemic. After this notice is published it is the duty of every inhabitant of Indianapolis of or over 6 years old, not immune to smallpox, to be vaccinated and a penalty is imposed on any person failing to do so. The Indianapolis Board of Health and Charities published in various newspapers a resolution stating that there was danger of a smallpox epidemic among school children, requiring all school children to be vaccinated, and excluding all unvaccinated children from school. The plaintiff, the father of an unvaccinated child excluded from school, sought to restrain the board from excluding his child from school. The trial court granted the injunction, after overruling the board's demurrer to the bill of complaint, and the board appealed to the Supreme Court of Indiana.

The plaintiff contended that there was in fact no epidemic. But, said the Supreme Court, the power to determine whether an epidemic exists is vested in the board of health and, in the absence of fraud or bad faith, the determination of the board is conclusive. The plaintiff next contended that the state statute authorizes the board to order what is reasonable and necessary for the prevention and suppression of disease only in connection with the establishment of quarantine, and that since no quaran-

## SOCIETY PROCEEDINGS

JOUR. A. M. A.  
SEPT. 29, 1934

time had been established, no right to order vaccination had come into existence. But, answered the Supreme Court, the statute also vests in the board the power 'to close schools and churches and forbid public gatherings in order to prevent and stay epidemics, and in all reasonable and necessary ways to protect the public health.' This language the court regarded as a conclusive answer to the plaintiff's contention.

The Indianapolis ordinance, said the court provides for and requires vaccination of every person over the age of 6 years, without any action by the board of health. The plaintiff contended however, that the board undertook to exercise powers which it did not possess and which were not conferred by the city ordinance, in ordering the vaccination of school children. But answered the Supreme Court the recital in the published resolution of the board that all school children must be vaccinated was merely declaratory of the law as fixed by the ordinance. The part of the ordinance which required initiative on the part of the board of health was the order excluding unvaccinated children from the schools. This the board had ample power to do. The legislature intended to delegate to boards of health ample power to protect and safeguard the health of the community and to vest in them authority to determine what reasonable steps are necessary to that end. The court thought that another statute making it the duty of a parent to send his child to school had no connection with the relation to the statute under which the board of health may exclude a child who has not been vaccinated against contagious disease. Nor was there any merit found in the contention that the resolution of the board violated those provisions of the United States constitution and of the constitution of Indiana prohibiting the abridgment of religious and civil liberties and matters relating to conscience.

The Supreme Court reversed the judgment of the trial court and directed that the board's demurrer be sustained.—*Conneget v. Baun (Ind.)*, 188 N. E. 677.

**Evidence Right of Medical Expert to Express Opinion as to Cause of Cerebral Hemorrhage**—The defendant insurance company issued to the insured a life insurance policy wherein it agreed to pay additional benefits if death 'resulted independently and exclusively of all other causes from bodily injuries effected directly from external, violent and accidental means of which there was visible contusion or wound on the exterior of the body.' Additional benefits were not payable if death resulted directly or indirectly, wholly or in part from any kind of illness or disease. The insured was injured in an automobile accident. He was found slumped over the steering wheel with bruises almost surrounding the orbit of his left eye. He died shortly thereafter without regaining consciousness.

His widow the beneficiary named in the policy brought suit in the district court of the United States for the northern district of Illinois against the insurance company to recover the additional benefits. A physician testified on behalf of the widow that the insured had died from a cerebral hemorrhage, which was probably induced by the insured's face striking the object which caused the bruises. Another physician, who had performed an autopsy on the body testified that the insured died from a cerebral hemorrhage due to high blood pressure and not to any injury from the accident. Another physician testified that there was no connection between the abrasions or contusions on the insured's face and the cerebral hemorrhage. The widow moved to strike the testimony of the latter two witnesses on the ground that it invaded the province of the jury. The motion was denied and later there was a judgment for the insurance company. The widow then appealed to the United States circuit court of appeals seventh circuit contending that the district court erred in admitting the testimony of the two witnesses.

In the trial of this cause said the circuit court of appeals the introduction of testimony was governed by the rules of evidence established by the Supreme Court of Illinois and on the point in question the Illinois rule was clearly stated in *City of Chicago v. Didier* 227 Ill. 571 81 N. E. 698 as follows:

There is some apparent confusion in the authorities on the question as to whether in such cases as this a medical expert may be asked his opinion as to whether the physical conditions of the injured party are the result of the injuries complained of. Where there is a conflict in the

evidence as to whether the plaintiff was injured in the manner claimed it is not competent for witnesses to give their opinions on that subject but where there is no dispute as to the manner of the injury and the question is as to whether certain physical conditions were caused by the injury complained of and the determination of the question involves a special skill or trade or a knowledge of science that does not come within the experience of laymen possessing the education or knowledge common to those moving in the ordinary walks and engaged in the ordinary occupations of life then persons possessing the special knowledge skill or science may give their opinions on the subject. Appellant contends that the inquiry should be as to whether the injury might have produced the physical conditions and not whether the injury might have but the weight of authority in this state as well as in other jurisdictions does not support appellant's contention. We think the apparent confusion of the authorities arises from a failure to distinguish between cases where the manner in which the injury is received is admitted and cases where the manner of the injury is denied.

In the instant case, there was no dispute whatever as to the happening of the accident, the manner in which it occurred and the observable bodily injuries. The controversy concerning which the experts were permitted to testify was as to the result of those bodily injuries and in the opinion of the court, under the Illinois rule the questions were proper. The judgment of the district court was accordingly affirmed.—*Alexander v. Missouri State Life Ins. Co.*, 68 Fed. (2d) 1.

**Hospitals, Charitable Liability for Burn with Hot Water Bottle**—The courts are practically agreed, says the Supreme Court of Errors of Connecticut that a charitable institution is not responsible to those who avail themselves of its benefits for any injuries that may be sustained through the negligence of its agents or servants in the selection of whom it has exercised due care. In the present case the plaintiff followed an operation received a burn from a hot water bottle placed in his bed, apparently by a hospital nurse. He sued the defendant hospital an institution organized and operated for charitable purposes. The trial court overruled a demurrer interposed by the plaintiff to the hospital's plea of nonliability because of its charitable nature and entered judgment for the hospital. On appeal the Supreme Court of Errors of Connecticut affirmed the judgment of the trial court.—*Cashman v. Meriden Hospital (Conn.)* 169 A. 915.

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

- Gonococemia with Recovery Report of Four Cases C K Friedberg, New York—p 271

**Bile Pigment and Hemoglobin Regeneration**—Patek and Minot selected nine patients suffering from chronic hypochromic anemia in order to determine whether bile pigment could assist in hemoglobin production. Concentrated bile pigment alone caused not a reticulocyte response but an increase of hemoglobin about 7 per cent in ten days. This indicates that in certain anemic patients bile pigment can be absorbed from the gastrointestinal tract for building hemoglobin. After a reticulocyte response occurred to a suboptimal dose of iron, bile pigment was fed directly with the same dose of iron and there followed a second reticulocyte response. The second response was sometimes of greater magnitude than the first. This indicates that bile pigment in some unknown manner can facilitate either iron absorption or utilization. One patient who could not obtain a normal hemoglobin level in fourteen months with large daily doses of iron, promptly increased her hemoglobin concentration when bile pigment was fed in addition to iron. In certain cases of hypochromic anemia there may be a deficiency of a useful material that is contained in bile pigment in addition to iron deficiency.

**Persistent Functional Albuminuria**—Burden found nothing in the medical histories or in the physical examinations of fifty-six otherwise healthy male students with persistent functional albuminuria to account for the urinary abnormality. The kidney function as determined by the phenolsulphonphthalein

and Mosenthal tests was normal. Cardiorenal disease in the parents of students with functional albuminuria was more than twice as frequent as in the parents showing no such abnormality. A tendency to low basal metabolism readings was found in 80.9 per cent, but in the ten cases tested with moderate doses of thyroid extract there was no improvement in the albuminuria. The blood serum calciums were normal in ten students with persistent functional albuminuria, although calcium medication had a favorable influence on the albuminuria in eleven of sixteen cases.

**Maxillary Sinus Studied by Means of Roentgenograms**—Sedwick studied the shape, size, position, variation and measurements of the sinus in a representative group of roentgenograms of both sexes of various ages. He observed that the maxillary sinus varies greatly in shape, size and position, not only in different persons but in each side of the same person. The sinus reaches its maximal size during the third decade of life and does not increase thereafter. In the later decades there is a definite tendency toward the assumption of the triangular form. When the sinus is triangular, the position of its base varies. The relation between the floor of the sinus and that of the nasal cavity varies and is not a characteristic of sex. The sinus is in close proximity to the sides of the nasal cavity. The only difference between the sinuses in the white and the Indian skulls examined is that the vertical height is less in the Indians, a fact that might be correlated with the shorter nose and broader cheeks of the race. The average measurements for the sinus, based on 173 cases or 346 sinuses, are height 34 mm, width 25 mm, and anteroposterior length 39 mm. The average maximal and minimal measurements are height, maximal 46 mm, minimal 22 mm, width, maximal 35 mm, minimal 17 mm, anteroposterior length, maximal 51 mm, minimal 29 mm. The average height for men is 35 mm and for women 34 mm. The average width for men is 25 mm and for women 24 mm. The average length for both men and women is 40 mm.

**Chronic Intermittent Duodenal Stasis**—Friedenwald and Feldman point out that in the intermittent type of duodenal stasis no pathologic changes are present, except those produced by superior mesenteric artery pressure associated with viscerospasm, adhesions and bands or spinal deformities, movable growths and masses involving the abdominal organs, or ptosis of the right kidney producing pressure on the duodenum. Intermittent duodenal stasis may likewise be brought about by lesions elsewhere in the digestive tract producing reflex disturbances of motility in the duodenum. This disturbance occurs most frequently in women during middle life. The symptoms are not always characteristic. They frequently manifest themselves in the form of bilious and migraine attacks, indigestion, headaches and chronic constipation. The patients are usually

of the enteroptotic type. The roentgenologic signs of duodenal stasis are well defined and characteristic and may be the only means of arriving at a positive diagnosis. Owing to the intermittent character of this condition, however, the stasis may be present at certain examinations and not at others, and repeated studies must therefore be undertaken. The definite proof of the presence of intermittent duodenal stasis is the demonstration of a definite prolongation of the emptying of the duodenum during or immediately following an attack. In the treatment a carefully regulated diet, maintaining the general nutrition, frequent postural change and abdominal supports are of benefit. The essential problem is directed to overcoming the traction on the duodenum and the effects of the associated visceroptosis. Surgical intervention should not be advised except as a last resort, and when indicated duodeno-jejunostomy or division of the constricting bands is the best procedure.

**Technic and Results of Cholangiography**—For the visualization of the sphincter of Oddi, the pancreatic duct and small intrahepatic ducts, Saralegui uses thorium dioxide sol. With the patient lying on his back the solution, heated to 37 or 38 C., is injected through the drainage tube and at the same time it is guided and observed through the fluoroscopic screen. It is necessary to inject enough opaque solution to be able to visualize all the intrahepatic ducts. Generally 20 or 30 cc. is sufficient, but more may be injected if necessary. The retention of the solution in the ducts does not produce any reaction, even in cases of total obstruction of the common duct. The results of five cases are reported.

Healing of Tuberculous Cavities. Study of Cavities in a Middle Age Group. L. H. Fales and E. A. Beaudet. Livermore, Calif.—p. 225.

**Artificial Pneumothorax in Tuberculous Diabetic Patients**—Wiener and Kavee treated twenty-six cases of active pulmonary tuberculosis complicated by diabetes mellitus with artificial pneumothorax. The cases chosen for treatment had active pulmonary tuberculosis with tendencies to progression and, with a single exception, were febrile. The age incidence of their patients closely approximated that observed in diabetic patients in the general population. In nineteen the left and in ten the right lung was collapsed. This number includes one in whom a bilateral pneumothorax was induced. The lesions were in the main those which have been described as the diabetic type best elicited with the aid of roentgenography. In the twenty-six cases, marked immediate improvement was noted in nine, slight symptomatic improvement in five, and no improvement in twelve cases, in three of which a free pleural space could not be found. The nine patients who showed marked immediate improvement are still alive and in excellent condition. Of these, six had bilateral lesions. They have been well for periods varying from twenty months to nine years. Of the five patients in whom only slight symptomatic improvement was noted soon after the initial induction, four died within a period of from five to nineteen months and one cannot be traced since he left the hospital. Eleven of the twelve patients who showed no improvement died within one and twenty months after the induction. The other patient did not improve at first, but subsequently, after the appearance of a massive effusion collapsing the lung quite completely, the course became afebrile and the disease quiescent. Improvement was often dramatic, with cessation of hemorrhage, decline of fever, and diminution of cough and quantity of sputum. The usual complications that occur following collapse therapy were observed just as frequently as in the nondiabetic tuberculous patient.

**Quantitative Intracutaneous Tests in Tuberculosis**—Lichtenstein performed quantitative intracutaneous tests with tuberculin TPT (Seibert), the precipitated skin-reactive protein fraction from synthetic-medium tuberculin, on practically all the adults in the Chicago Municipal Tuberculosis Sanatorium within a period of a few weeks, with a view to determining the reliability of the product, the proportion of sensitive and nonsensitive patients and the relation of the level of skin sensitivity to various associated factors. Practically all the tuberculous patients reacted to TPT (Seibert) intracutaneously, with the exception of a few on the verge of death. 97.7 per cent reacted to the 1:1,000 dilution. Two thirds of those who did not react to this dilution were moribund. About one third (all of whom reacted to the 1:100 dilution) are still alive six months later. Quantitative studies indicate that skin sensitivity is progressively depressed with advancement of the lesion, with an increasing duration of the disease and with an increasing severity of the symptoms. Skin sensitivity is progressively increased with increasing degrees of lung compression. No evidence was found that allergy influences immunity. It seems rather that immunity indirectly influences allergy through the liberation of antigen.

**Follicular Lesions in Vitamin A and C Deficiencies**—Scheer and Keil report two cases of scurvy in adults, in which follicular lesions were present. In one instance the resemblance of the lesions to those described in vitamin A deficiency was striking, in the other the characteristic perifollicular papule of scurvy revealed such striking differences as to warrant separation from the lesion observed in vitamin A deficiency, in which the fundamental pathologic change seems to be in the epithelium, resulting in hyperkeratosis of the epidermis and of the hair follicles. The lesion is not accompanied by inflammatory changes in the cutis (except secondarily), and, most important, hemorrhage does not seem to occur. Ulceration appears to depend on the lowered resistance of the tissues in patients who are undernourished. On the other hand, the fundamental process in scurvy resides in the capillaries of the upper cutis in the region of the hair follicles. As a secondary result the hyperkeratosis is mainly limited to the hair follicles. Early in the process, hemorrhage of a minor degree occurs interstitially. This is, however, not always clinically discernible. In the authors' second case, the dull red color of the papule was explained by the congestion in the perifollicular capillaries and the moderate interstitial hemorrhage. When the hemorrhage becomes sufficiently intense the typical perifollicular petechia of scurvy results. This was artificially accomplished in the second case by means of the tourniquet test, in which the maximal capillary fragility was demonstrated to be almost entirely confined to the perifollicular vasculature. The early occurrence of a positive tourniquet test, which becomes negative when the disease is properly treated, illustrates the point that vascular damage is the fundamental pathologic process in scurvy.

**Rare Sweat Gland Tumor Syringocystadenoma Nodularis**—Sutton cites a case in which discrete nodules appeared unilaterally on the neck of a woman, aged 45. Histologic examination led to a diagnosis of a rare form of tumor of the sweat glands. The origin in the sweat glands was postulated on the observations that the tumor was of two-layered epithelial cylinder structure and that less highly evolved nodules of syringoma occur at the periphery of larger nodules. The basic architectonic scheme of the nodules in this case is the secretory tubule surrounded by neoplastic proliferation of sheath cells. It is conjectured that a sudoriparous neoplasm with the growth urge emphasized on the secretory cell layer produces the classic syringocystadenoma, while, if sheath cells are predominately active, firmer, larger nodular growths occur, as seen in this case and in that of Paul and Adamson. The case described is an instance of tumor of the sweat glands, microscopically cystic and alveolar in structure, and clinically nodular in appearance, it is properly named syringocystadenoma nodularis.

**Neurocutaneous Syndrome Congenital Ectodermoses**—Kulchar and Anderson present a case that does not conform to any of the three heretofore recognized types of the neurocutaneous syndrome. The widespread distribution of the congenital anomalies involving the face, extremities, spinal cord and probably the brain is the most unusual feature. The occurrence of the nevi on the extremities in association with changes in the central nervous system is infrequent in the heretofore reported cases of the neurocutaneous syndrome. Cobb reported a somewhat similar case in which the nevi were few and small, while the lesion of the spinal cord was localizable at the level of the same metamere. In their case the authors assume, in view of the wide distribution of the nevi and the signs indicating an extensive abiotrophy or a gliosis of the central nervous system, that the malforming factor must have become operative before the ectoblast had reached any considerable degree of differentiation. Skeletal anomalies such as the patient presented were reported by Goodhart as occurring in von Recklinghausen's neurofibromatosis. Brooks and Lehman cited scoliosis as being among the characteristic changes in the bone in von Recklinghausen's disease. Whether the scaphocephaly, dactylomegaly, syndactylism and scoliosis noted in the patient are analogous changes must remain conjecture, but it is possible that a malforming factor becoming operative early in the stage of embryogenesis might result in skeletal anomalies. The possibility that lowered mentality in the patient may be the result of Bourneville's tuberous sclerosis involving the cortex of the frontal lobe must await confirmation at necropsy. Under the classification of Yakovlev and Guthrie the neurocutaneous syndrome, or the "congenital ectodermoses" as they term them, may be divided into (1) von Recklinghausen's neurofibromatosis, (2) Bourneville's tuberous sclerosis and (3) the encephalotrigeminal vascular syndrome (angiomatosis of the brain associated with cutaneous nevi in the area of trigeminal distribution).

**Tumor of Orbit in Osteochondrofibrosarcomatosis**—Goldstein and Wexler report a case of sarcoma in an orbital bone in the presence of a similar growth in other parts of the body, which differs from the few reported instances of metastatic orbital sarcomas in that it is not possible to point with accuracy to the primary source of the new growth. Except for the invasion of adjacent muscle tissues by the tumor, the growth was confined to separate skeletal bones. Although the first symptoms pointed to a primary growth in the dorsal spine, the possibility of a more or less simultaneous involvement of the bones concerned, i. e., multiple sarcomatosis, could not be ruled out with certainty. Such a diagnosis was supported by the

embryonic character of the cellular and fibrous tissues in all the masses studied and by the presence of immature cartilage and bone. It appears that undifferentiated tissues in these various areas received suddenly a stimulus to grow and assumed the proportions of malignant tumors.

**Pneumococcus Chain Formation**—Bullock and Wilcox describe the phenomenon of chain formation in pneumococci and its association with "rough" colonies and lowered virulence for mice. The occurrence of chainwise growth of pneumococci in severely ill patients suggests the possibility that the infection may be due to some other organism, either a streptococcus or a pneumococcus of another type. Chainwise appearance occurring in pneumococci recovered from the blood should not be a deterrent to the use of available specific serum, as the appearance of chain formation may be due to a partial protection in the blood. This protection may become exhausted. The cases for the most part appear to be less severe than pneumonias due to pneumococci that do not form chains.

**Dietary Treatment of Undernutrition**—The use of insulin to increase the weight of persons who are underweight seems to Brown and Ralli to be unnecessary, except for the occasional patient who lacks the appetite to eat a high calory diet. Aside from the inconvenience there is the possibility of hypoglycemia, hyperglycemia and glycosuria. The ability of a person to gain weight depends on his taking in more energy than he puts out. That this can be accomplished by means of a high calory diet the authors show by a group of six subjects and a group reported previously. The chief effect of insulin in undernutrition is its ability to stimulate the appetite. This makes it easier for the patient to eat a large amount of food. The gain in weight is due to the increased caloric intake. If the patient does not eat insulin will not increase the weight. The authors had under treatment a patient 23 years of age to whom insulin was given three times daily before meals, 10 units before breakfast, 15 before lunch and 15 before supper. The patient had hypoglycemic reactions almost daily, but an increased appetite was not experienced. She refused to eat the entire diet and during a period of three weeks gained exactly 4 pounds (17 Kg). When one considers that an impaired tolerance for carbohydrate may follow the use of insulin in nondiabetic persons and since a satisfactory gain of weight will follow the ingestion of a high calory diet, it seems that the indiscriminate use of insulin in undernutrition is inadvisable.

**Modification of Radiopaque Mass for Injection of Lumens**—Poth believes that bismuth oxychloride makes a satisfactory substance for injection of lumens, not only because of the high atomic number of bismuth and its consequent opacity

to  $\alpha$ -radiation but also because of the physical properties of the compound. The bismuth oxychloride used is extremely finely ground and will assume definite physical properties when suspended and ground in acacia solutions. After such a suspension has been ground for some hours in a jar mill, the particles arrange themselves in chains less than half a micron thick and from 3 to 4 microns long. On standing for fifteen minutes the chains arrange themselves into spherical rosetts about 8 microns in diameter. No larger particles are formed regardless of the density of the suspension, except on long standing. The greatest density of any mass suggested by Hill contains 0.4 Gm of bismuth oxychloride per cubic centimeter and, as he states, this is a paste. By the method of preparation that the author presents, the most satisfactory mass for arterial injection contains 0.5 Gm per cubic centimeter and has the consistency of a thin cream. Injection of this material at a pressure equal to the normal blood pressure of the animal usually gives satisfactory visualization of the arterial tree, extending out to minute arterioles without the fogging attendant on capillary shadows. In the preparation of the mass, the proportion of acacia to bismuth oxychloride taken is 1:2. The quantity of water varies with the density of suspension desired. The unmixed ingredients are placed in a glass fruit jar or ball mill crock one-third filled with ordinary glass marbles. This is placed on a ball mill, such as is commonly used by chemists for grinding materials extremely fine, and is allowed to grind for from two to three days. These suspensions are still unstable and will settle out appreciably after standing several days, and so it is advisable to regrind for an hour or two before making injections.

**Reduction of Premature Infant Mortality**—Clifford suggests that the premature infant mortality may be reduced through knowledge as to the probable weight of the fetus in utero and as the result of an analysis of the influence of various obstetric factors on the viability of premature infants. From a study of 958 premature infants the author concludes that: 1. The viability of the fetus does not appear to be influenced directly by the complication of pregnancy present in the mother. However, it is affected indirectly by what that complication does to the placental circulation and by the method selected for the treatment of that complication. 2. The future of the premature infant is tremendously affected by the method chosen for its delivery, in general, delivery by the present technique of cesarean section or breech extraction is accompanied by a much higher infant mortality than is vertex delivery assisted by the application of low forceps. 3. The premature infant mortality is greatly increased by the maternal administration of morphine within four hours of delivery. The author feels that the practical application of these factors during the past year has contributed to the following results: 1. The general stillbirth rate was reduced from a ten-year level of 69 per thousand deliveries to 47 per thousand for 1933. 2. The incidence of premature infants alive at birth increased from an average of 27.6 for the preceding ten years to 34.7 per thousand deliveries for 1933. 3. The number of premature infants weighing from 4 to 5 pounds (1.8 to 2.3 Kg.) increased from an average of 52 per cent for the preceding ten years to 61 per cent for 1933. 4. The premature infant gross mortality dropped for the first time in five years from a level at 35 per cent to 29 per cent. The mortality rate for infants weighing from 3 to 4 pounds (1.4 to 1.8 Kg.) was reduced from 40 per cent for the preceding ten years to 24 per cent for 1933.

**Streptococcus Hemolyticus in Throats of Children in Hospital Wards**—Burgin and Higgins observed that there is considerable variation in the incidence of Streptococcus hemolyticus carriers in the ward of a hospital from week to week during the fall and winter season. There appears to be a monthly peak in the incidence of carriers. In these observations two peaks of greater magnitude than the others occurred in November and March. This may be an indication of an epidemic respiratory infection in the whole community at that time. Members of the nursing staff tend to become carriers at the "peak" periods. The incidence of carriers among 178 children was 43.8 per cent and was about as common in a room of noninfectious eye cases as in rooms with many operative mastoiditis cases. The carrier rate among patients with tonsils was higher than among those without tonsils. There is no characteristic appearance of the carrier's throat that makes diagnosis possible without culture.

- \*Treatment of Pulmonary Tuberculosis by Bronchial Occlusion. Experimental Study. W. E. Adams and A. J. Vorwald. Chicago—p. 633.

**Effect of Sudden Occlusion of Pulmonary Artery on Cardiac Output**—Moore and his co-workers observed that the total circulation can be shunted through either lung in anesthetized dogs without any significant change in cardiac output. The decrease in cardiac output that has been observed after complete occlusion of one primary bronchus is not due to resistance to the passage of blood through the atelectatic lung. The expansion of a lung is affected by its pulmonary circulation, decreasing when the pulmonary circulation is interrupted and increasing when the pulmonary circulation is increased.

**Chemical Destruction of Periosteum in Treatment of Chronic Empyema**—On the basis of his experiences in fifty cases of severe fistulous postpneumothoracic empyema, Jachia concludes that the Schede method is too complicated and severe so that it cannot be used for all patients. In the cases in which recovery is obtained, the result is secured only at the cost of numerous interventions with long residence in hospitals. The thoracic resection of Schede is really adapted for the treatment of empyemas occupying only a part of the hemithorax. The Estlander procedure, however, allows the operator to stay away from the infected pleura and is in itself a less severe operation and surgically more nearly correct because it involves only zones that are not infected. But the Estlander method, when used for tuberculous patients, does not always give the desired result. The use of Zenker's solution prevents the new formation of bone, being nonoffensive, it does not disturb the regular cicatrization of the operative wound, and it facilitates appreciably the radical therapy of chronic empyemas.

**Treatment of Pulmonary Tuberculosis by Bronchial Occlusion**—According to Adams and Vorwald, atelectasis of pulmonary tissue brought about by bronchial occlusion exerted a favorable influence on experimental pulmonary tuberculosis in dogs, whether induced by hematogenous or bronchogenic infection or by direct inoculation. Tubercles in the collapsed lobes were in general small and almost free from bacilli, whereas in inflated lobes in the same animals they tended to be large, often confluent, caseous, and rich in acid-fast bacilli. The favorable effect in the collapsed lobes increased with the duration of the collapse and in some cases amounted to a complete cure of the disease. This beneficial influence may be attributed to several factors: absolute rest, decrease in oxygen and increase in carbon dioxide. Tuberculous lesions were produced with routine regularity either by hematogenous or bronchial infection or by direct inoculation, and the influence of

collapse on these lesions could be extremely well evaluated. Little difficulty was encountered in producing complete stenosis of a bronchus not discharging pus. When a discharge was present, repeated applications of the cautery were necessary to effect complete occlusion. Bronchi closed in man as readily as in dogs. Little or no reaction attended the application of the cauterizing agent in human cases.

**Monocyte-Lymphocyte Ratio as Measurement of Activity in Pulmonary Tuberculosis**—To determine whether the monocyte-lymphocyte ratio is of any practical aid in evaluating activity in pulmonary tuberculosis, Muller analyzed the blood counts of 800 consecutive admissions at the Rutland State Sanatorium. The counts were all made by one person on fixed coverslip smears, according to standard procedures. Among the 800 admissions there were 730 cases of pulmonary tuberculosis, thirteen cases of childhood type and, as a rule, inactive tuberculosis, seven cases of pleurisy with effusion and fifty nontuberculous cases. The monocyte-lymphocyte ratio of the 730 patients has been correlated with various factors: the stage of the disease, prognosis, temperature and pulse during the first week after admission and the results obtained during the time of observation. In the group classified as minimal tuberculosis

or stage I, the greatest number of cases showed a normal or nearly normal ratio, and no patient was classified as having minimal tuberculosis with a ratio of more than 0.9. The cases classified as stage II, or moderately advanced, show the same trend as those of stage I, while the proportion of far advanced cases, or stage III, gradually increased with the ratio to a total of 94 per cent when this ratio reached 1.25 or more. Comparing clinical judgment with the objective observation of the monocyte-lymphocyte ratio, there was a surprisingly close correlation between these factors. The number of patients given a favorable prognosis decreased as the ratio increased and vice versa. During the first week in the sanatorium 189 per cent of the patients had elevated temperature and 51.3 per cent increased pulse rate in the group with normal monocyte-lymphocyte ratio. The proportion of patients having an elevated temperature and pulse rate above normal increased progressively with the ratio but did not reach 100 per cent in any one group. In the group of 111 patients having a normal monocyte-lymphocyte ratio, 88.2 per cent improved. As the percentage of improving cases decreased, the monocyte-lymphocyte ratio increased. It also increased proportionally to the increasing number of unimproved or fatal cases. That some patients having tuberculosis will have a normal monocyte-lymphocyte ratio is illustrated. In the group of patients giving a monocyte-lymphocyte ratio of 1 or more sixteen improved. In the presence of a high ratio a favorable prognosis is not always justifiable, although, from the results obtained, a high ratio must be considered with grave concern. A high ratio may be accounted for by various factors, the nature of which must be carefully studied in order to avoid misleading interpretation. Into this category enters an acute onset with a cold, bronchopneumonia, pneumonia or pleurisy. Successful active therapy may also bring about a rapid change in the monocyte-lymphocyte ratio. However, 25 per cent of the patients with a ratio of more than 1 died within three months. All stages of activity were represented between the groups with normal and high ratios.

**Treatment of Pruritus Vulvae by Alcohol Injection**—Wilson applied the alcohol injection method of Stone for the treatment of pruritus and in five cases of pruritus vulvae, four cases of pruritus vulvae with chronic vulvitis, one case of pruritus vulvae with chronic hypertrophic ulcerative vulvitis, and five cases of pruritus vulvae with leukoplakic vulvitis. The vulva is as carefully prepared as it would be for surgery. The patient is then anesthetized, general anesthesia or intradermal infiltration (procaine 2 per cent) being used. The alcohol is injected with a 2 cc hypodermic syringe calibrated in minims. The needle is inserted perpendicular to and through the skin so that the alcohol will be deposited just beneath the dermis. Only 3 or 4 minims (0.2 or 0.26 cc) of 95 per cent alcohol is injected at a single insertion of the needle. The number of injections for any one structure or area depends on the extent of the itching, the age of the patient and the condition of the peripheral circulation as well as the estimated efficiency of the circulation of the part to be injected. When the skin is in fair condition and the circulation seems unimpaired, one may inject as much as 4 minims of alcohol into every square centimeter of the itching areas. When the skin is much thickened or excoriated or the circulation is impaired, the injections must be made at wider intervals and only 2 or

administration on two occasions. The drug had no effect whatever on hookworms and tapeworms. *Oxyuris* is easily expelled by such purgative drugs as mild mercurous chloride and salts, but the number expelled when these were combined with *Vernonia anthelmintica* was considerably larger.

**Basophil Adenoma of Pituitary Gland**—Russell and her associates describe two fatal cases in which a basophil adenoma of the pituitary gland was suspected at necropsy because of the physical appearance of the subjects and the presence of a conspicuous degree of cardiovascular hypertrophy. In the first case the possibility of a pituitary tumor had been considered at an early stage of the illness on account of the severe headache, obesity and impotence but was abandoned when the roentgen examination was negative. After that the case was regarded as one of essential hypertension. Finally, the observation of albuminuric retinitis suggested the presence of a malignant hypertension (nephritis repens), and this suspicion was later justified by the manner of death. Several of the principal clinical features of Cushing's syndrome could be identified: the obesity of peculiar distribution associated with abdominal striae, hypertension, plethora, skin hemorrhages and impaired sexual function. The obesity was, however, transitory. The skin hemorrhages were terminal and were doubtless due to the nephritis. Certain changes claimed as part of the syndrome were lacking—osteoporosis and skeletal deformities, glycosuria and hypertrichosis. In the second case repeated albuminuria of pregnancy was associated with raised blood pressure without nitrogen retention. Cardiovascular hypertrophy, obesity and a moderate degree of hypertrichosis were the only physical features suggesting pituitary adenoma. The obesity had been present for at least nineteen years. This and the general distribution of adipose tissue over the trunk and limbs are deviations from Cushing's syndrome in which the fat is acquired rapidly at a shorter period before death and spares the limbs. Abdominal striae were present but may have been due to the previous pregnancies. There was no amenorrhea. The patient did not complain of aches and pains. They believe that these two cases, considered in conjunction with those reported elsewhere, suggest that the correlation between basophil adenoma, obesity and persistent high blood pressure is close. They show that the correlation, if it exists, is between basophil adenoma and high blood pressure as such, and not between basophil adenoma and chronic Bright's disease.

**Treatment of Asthma by Dorsal Perisymphathetic Injection of Alcohol**—Levin injected absolute alcohol into the bronchial sympathetic nerves in the treatment of sixteen patients suffering from bronchial asthma, the majority of whom were thought to be so-called incurables. In ten cases there was complete relief after four to eight injections, in one case there was sufficient improvement after two injections

for the patient to discontinue treatment, in three cases there was considerable improvement after two or three injections and in two cases the improvement was only slight. For the injection the patient is seated leaning forward, the hands resting on the knees, the spine is arched backward and the tips of the shoulders are drawn in so as to allow the maximal retraction of the scapulas. A point is selected 4 cm. away from the spine, preferably in the third, fourth, fifth or sixth intercostal spaces. A few drops of procaine hydrochloride is injected intradermally so as to raise a wheal, the needle carrying the absolute alcohol is introduced perpendicularly just above the space to be injected down to the inferior margin of the rib, as soon as the rib is felt the needle is directed slightly downward and 45 degrees forward and inward to the depth of about 2 cm. away from the lower margin of the rib. The point of the needle is now between the external and internal intercostal muscles. The needle is pushed slightly farther inward toward the spine and about 2.5 cc. of absolute alcohol is slowly injected, the position of the needle being altered slightly for each spurt. Usually a sharp pain is felt in two or three interspaces immediately below the site of injection. Two or three intercostal nerves can be dealt with at the same sitting. The only possible complication is injury to the pleura. The entry of the needle into the pleural cavity can be observed by the thick velvety feel of the pleura and by a hissing noise due to the entry of air, therefore it is preferable to introduce the needle alone without the syringe. In doubtful cases the needle should be connected with a manometer, and the presence or absence of respiratory excursions of mercury will show whether the needle is or is not in the pleural cavity.

Physiopathology of Denutrition of Nursing L. Garot—p. 239

**Emesis of Early Infancy**—Ribadeau-Dumas and Barraud report four cases of vomiting in infants, which disappeared when the infants were placed in certain positions. In the first case, serious vomiting and emaciation continued until the child was placed prone on the abdomen until the end of digestion. Vomiting reappeared when the infant was placed on the back again. The second case was complicated by a concurrent infection. The authors believe that the vomiting in the first two cases was due to compression of the third portion of the duodenum by the superior mesenteric artery. In the third case it appeared to be due to pressure on the stomach from a syphilitic hypertrophy of the liver and spleen. After mercury rubs the infant was able to eat in any position. In the final case lying on the left side caused a cessation of vomiting, and the authors believe that the cause of vomiting was poor gastric peristalsis.

### Presse Médicale, Paris

- \*Treatment of Erythremia (Vaquez's Disease) with Phenylhydrazine H. Vaquez and M. Mouquin—p. 1065  
\*Treatment of Tuberculous Hemoptysis by Subcutaneous Injections of Oxygen A. Courcoux—p. 1068  
Diagnosis of Hyperthyroidism by Electrical Test P. Sainton and Lamy—p. 1069

**Treatment of Erythremia**—Vaquez and Mouquin discuss the treatment of erythremia with phenylhydrazine. The principal objection to the use of phenylhydrazine, that of its toxic effects, they believe exaggerated and largely due to overdosage. The effects on the kidney, spleen and liver are almost always transitory. This was true at least in their own cases. Venous thrombosis is not rare in the course of erythremia and cannot be definitely assigned to the treatment. They have never observed it, but the two fatal cases analyzed by Giffin and Conner showed faulty technique. Treatment with phenylhydrazine

should have the double object of bringing the erythrocytes to a normal number and then maintaining them there. The dose required for these two purposes naturally differs. They introduce treatment by giving phenylhydrazine hydrochloride in a dose of from 0.05 to 0.1 Gm, depending on the weight of the patient and the degree of polycythemia. On the fourth day the blood is examined and if there is no change the dose is increased by 0.05 Gm for another period of four days, when the procedure is repeated. It is wise, even with apparent therapeutic failure, to suspend medication after the patient has taken a total of 3 Gm. When the count has reached the desired level, they give from 0.1 to 0.2 Gm per week on one, two or three consecutive days. When the proper dose has been determined for the individual, it is kept at this level since there is no habit formation. In occasional cases apparently permanent cures result. They cite one such in which the erythrocytes remained normal without phenylhydrazine for eighteen months.

**Treatment of Tuberculous Hemoptysis**—Courcoux followed up the observations of Ravina, Benzaquen and Bibas on the effect of subcutaneous injection of oxygen on stopping pulmonary hemorrhage. He systematically injected oxygen subcutaneously in thirty-four cases of hemoptysis. The technique was simple and consisted in the rather rapid subcutaneous injection (usually in the thorax) of a considerable quantity of oxygen. The volume injected varied between 300 and 600 cc, but better results were obtained with the larger quantities as a rule. Repeated injections were without bad effects. In twenty-five cases the arrest of hemoptysis was immediate and definite. In six cases several repeated injections on consecutive days were necessary to obtain a good result. In seven cases the hemoptysis continued apparently unaffected. No other therapeutic procedures were used. The author does not speculate on the mechanism involved.

Aneurysm of Pulmonary Artery. Case U. Borghetti—p. 1075

\*Behavior of Cholesterolemia in Surgical Diseases of Infancy. V. Bernabeo—p. 1080

**Cholesterolemia in Surgical Diseases of Infancy**—Bernabeo determined the amount of cholesterol in the blood of infants before and after surgical intervention. He found that the cholesterolemia showed a marked increase two hours after ether anesthesia and operation in children having surgical lesions. This increase lasted twenty-four hours and then gave way to an appreciable decrease. By the fifth day the cholesterol had diminished to its rate before operation. Children subjected to longer and more traumatizing operations showed a lower rate of cholesterolemia five days after operation than before. In septic surgical lesions no rise in cholesterolemia was observed before operation except in cases of long duration, such as osteomyelitis and tuberculous lymphoma of the neck. In septic surgical lesions twenty-four hours after operation there was a slight hypercholesterolemia, which rose steadily for five days. This was partly attributable to the fall of the fever of the patients. After ten days the rate returned to normal. Children having surgical lesions but not evincing need of surgical intervention showed a higher rate of cholesterolemia than previous groups. The cholesterolemia decreased by the fifth day only to rise after the tenth and then to return to normal by the twentieth day. On the basis of these investigations the author concludes that all surgical lesions of infancy (traumatic, infective and suppurative) show a hypercholesterolemia whether they are operated on or treated by other than surgical intervention.

Pneumothoracotomy in Treatment of Exudative Pleurisy. G. La Torre—p. 1136

**Rapid Cantani Test in Syphilis**—Versari states that three reagents are necessary for making the Cantani test. Reagent A consists of 56 Gm of powdered ox heart 300 cc of 95 per cent ethyl alcohol, 150 cc of 99.2 per cent ethyl alcohol and 25 Gm of cholesterol; reagent B consists of 20 Gm of egg lecithin 370 cc of 95 per cent ethyl alcohol and 375 cc

of pure phenol; reagent C consists of 225 cc of 95 per cent ethyl alcohol, 25 cc of pure phenol and 0.1 cc of a 5 per cent solution of petrolatum in benzine. One part of reagent A, one part of reagent B and 0.5 part of reagent C are placed in a tube with two parts of a 3 per cent solution of sodium chloride. The suspension obtained is turbid and tends to accumulate on the surface. It is shaken for seven minutes before using. In the meantime, eight times the original amount of sodium chloride solution is put in another tube and after seven minutes the contents of the second tube are poured into the first tube and thoroughly mixed. Twenty-five hundredths cubic centimeters of the mixture is poured into the tubes (generally five) containing the serum to be examined, the tubes are shaken at the rate of from 150 to 200 times per minute for four minutes, then left at rest for two minutes, and 2 cc of an 0.85 per cent solution of sodium chloride is added to each tube. Results are read immediately and again after from fifteen to twenty minutes. Negative serums show opalescence without flocculation, positive serums, clear flocculation, strongly positive serums, heavy flocculation with clarification of the liquid. The author found that in secondary syphilis with external manifestations the reaction is always positive compared with the Wassermann and Müller reactions. The Cantani test shows less positivity than the other reactions in cases of primary syphilis, of tertiary syphilis with latent or obscure manifestations, treated or not treated, and of nervous and congenital syphilis. In patients free from syphilis but presenting various acute or chronic diseases the Cantani reaction was always negative, whereas the Wassermann reaction gave 0.7 per cent nonspecific positive results and Müller's reaction 2.83 per cent. The Cantani reaction like the other tests always showed negative results in healthy persons. The author observed that the reaction had an index of specific sensitivity amounting to 52.38 per cent, while the Wassermann had 75.49 per cent and the Müller 80.02 per cent.

\*New Albuminoid Reaction of Superposition in Cerebrospinal Fluid. M. Gorriz and P. Martinez—p. 761

**Albuminoid Reaction of Superposition in Cerebrospinal Fluid**—Gorriz and Martinez present the following technique. Two cubic centimeters of the reagent, consisting of 8 Gm of corrosive mercuric chloride, 1 Gm of sodium chloride, 2 Gm of trichloroacetic acid 20 cc of a 40 per cent solution of formaldehyde, 10 cc of petroleum ether and 170 cc of water is placed in hemolysis tubes of 100 by 10 mm. The corrosive mercuric chloride must be dissolved by heat, after which the sodium chloride is added. The remaining products are added in the order indicated, and the liquids when the mixture is already cold. Afterward it is filtered. The reagent keeps for months without protection from light. If after some time a slight precipitate is formed at the bottom, the solution is filtered again without losing any of its coagulating power. Two cubic centimeters of the reagent is carefully deposited in the bottom of the hemolysis tube and, on top of it, the cerebrospinal fluid so as not to produce a mixture of the two fluids. If there is a large amount of cerebrospinal fluid, 1 cc may be used, and if less, 0.5 cc is sufficient. In a few minutes a white ring of precipitated albumin forms at the zone of contact, increasing in size and showing its maximum in fifteen minutes. The use of the water bath shortens the time of the reaction. After about thirty minutes, or sooner if the fluid is normal and the reaction negative, the precipitation of the albumin coagulated in the ring begins in the form of fine granulations, which slowly fall to the bottom. The highly positive reactions were characterized by a flocculent veil, which took form after fifteen minutes and dropped to the bottom of the tube in about ninety minutes. When a large amount of albumin is present, the veil grows into a heavy mass which is immediately precipitated to the bottom. The reaction is sensitive and simple. All fluids from normal subjects showed a negative reaction. In pathological cases invol-

ing neurologic or psychic processes the test always evinced the greatest sensitivity to the slightest alterations in the amount of albumin or globulin. The reactions were generally positive in cases of schizophrenia, epilepsy and alcoholism.

**Pregnancy Reaction According to Kapeller-Adler**—Olliglmacher studied the pregnancy reaction that was first described by Kapeller-Adler (abstract in THE JOURNAL, April 14, p 1265). He found that the color shades indicating a reaction are not distinct and that they fade into one another so that in some cases differentiation of a positive and negative test is impossible. His studies were made on 237 specimens of urine. Of the 145 specimens from nonpregnant persons, 128 gave negative reactions, 10 gave positive ones and 7 gave doubtful ones. Among 76 pregnant women the reaction was positive in 44, doubtful in 2 and negative in 30. During the puerperium, 13 women gave negative and 3 positive reactions. Since the incorrect results were especially frequent during the early stages of pregnancy (11 negative and 13 positive), the author concludes that the reaction is of no value for the diagnosis of pregnancy. He admits that the reaction may be reliable for the detection of histidine in the urine, but histidine elimination is not a constant symptom of the beginning stages of pregnancy.

**Influence of Copper on Experimental Hyperthyroidism**—Meyer points out that Hesse was able to counteract thyroxine poisoning in dogs by means of the administration of copper. In mice, copper effected only a partial protection against thyroxine poisoning and in rabbits this detoxicating action of copper failed completely. These results, differing in the various species of animals, induced Meyer to investigate what effect the administration of copper has on thyroxine poisoning in human subjects. In four tests on himself, in the course of which copper and thyroxine were administered simultaneously, the behavior of the basal metabolism, of the pulse frequency, of the weight and of the serum lipase was watched. It was found that the oral administration of copper does not counteract the characteristic action of orally or intravenously administered thyroxine. The serum lipase of a human subject shows a considerable reduction following administration of thyroxine and this reduction is noticeable also in case of the simultaneous administration of copper.

**Liver Therapy in Granulocytopenia**—Von Bonsdorff describes two cases of granulocytopenia (agranulocytosis), in which the parenteral (intramuscular) administration of liver extract proved helpful. Both cases were so severe that their spontaneous cure must be considered highly improbable. In discussing the action mechanism of this treatment the author points out that, if liver treatment is employed in pernicious anemia the leukopenia characteristic for this disease is also favorably influenced, a process which indicates that the liver extract influences the leukopoietic apparatus. Moreover, the regeneration of the erythrocytes in the regeneration of granulocytopenia. The author points out that the literature reports nothing about the behavior of the reticulocytes in granulocytopenia. He assumes that a disturbance in the regeneration of the erythrocytes should be demonstrated much more frequently by the increase in the leukocyte values concurred with the reticulocytosis, a factor indicating a relation between leukopoiesis and erythropoiesis. Since observations on the two reported cases indicate that parenteral liver therapy is helpful in granulocytopenia the author advises the trial of this treatment on a larger material.

### Medizinische Klinik, Berlin

- 30 985 1016 (July 27) 1934 Partial Index  
\*Causes of Heredity and Surgery A Ritter—p 985

Roenigen Therapy of Basophile Adenoma of Hypophysis C V During Childhood K. Hundemer—p 994  
\*Does Gargling Accomplish Its Purpose? T von Liebermann—p 994

**Causes of Mammary Secretion**—Winter's investigations are concerned with the mammary secretion in general and not only with the lactation setting in after delivery. He calls attention to the mammary secretion occasionally setting in during amenorrhea or during phantom pregnancy. Observations in cases of phantom pregnancy indicate the importance of nervous factors. In summarizing his discussion the author states that a modification of the mammary function can be accomplished by the various hormones as well as by nervous factors, and he assumes that vitamins likewise may play a part. In the establishment of the close relation between vitamins and hormones, products of the anterior lobe of the hypophysis seem to be of primary importance. The hormone of the anterior hypophysis the sympathetic nervous system and the ovarian hormone form an inseparable unit. The author aimed to show that the changes taking place in mammary secretion are not produced by a single hormone but that a number of factors are necessary to produce them. He emphasizes that animal experiments and clinical observations must go hand in hand if a clear insight is to be gained into these processes.

**Diagnosis of Basophile Adenoma of Hypophysis**—Medvei and Wermer after commenting favorably on Cusling's paper on hypophyseal basophilism, describe briefly the most characteristic symptoms: obesity, skeletal changes, red striae particularly on the obese portions of the body, redness of the face, hypertrichosis that is noticeable particularly in the female patients, and dryness of the skin. Clinical examination often reveals high arterial pressure and diabetes mellitus. The function of the gonads is nearly always impaired in women there is observed in hypophyseal basophilism occur also in patients with tumor of the suprarenal cortex and in certain ovarian tumors that lead to changes in the sexual characteristics (granulosa cell tumors and arrhenoblastomas). The differentiation of these conditions may therefore present difficulties. In the differentiation between hypophyseal basophilism and tumors of the suprarenal cortex, changes in the external female genitalia may be helpful, for in case of tumor of the suprarenal cortex the genitalia often show a decided tendency to virilization, some times to the extent of a pseudohermaphroditism, while in hypophyseal basophilism there are no such changes in the external genitalia. The red striae and the skeletal changes, particularly osteoporosis, which are characteristic for hypophyseal basophilism, have been observed also in case of tumor of the suprarenal cortex, in which they seem to be the exception rather than the rule. In the aforementioned ovarian tumors obesity and diabetes mellitus are extremely rare, while hypertrichosis is much more pronounced than is the case in hypophyseal basophilism. The virilization reaches a high degree in these ovarian tumors and as a rule these gonadal tumors are palpable.

**Does Gargling Accomplish Its Purpose?**—Von Liebermann says that some investigators charge that gargles are superfluous because the fluid does not reach the posterior wall of the pharynx but only up to the line formed by the posterior rim of the soft palate. The author points out that his studies on gargling do not entirely agree with the criticism of gargling voiced by Zimanyi and others. Zimanyi's experiments have value in that they call attention to the inadequacy of superficial gargling and the desirability of gargling in such a manner that the fluid is almost swallowed and is prevented from entering the stomach only by the outstreaming air. Children should be treated with gargles only in exceptional cases. Gargles are also effective in loosening the mucus and thus facilitate its expectoration.

**Munchener medizinische Wochenschrift, Munich**  
81 1119 1156 (July 27) 1934 Partial Index

- Roentgen Therapy of Skin Diseases F Bering—p 1119  
Prevention of Eclampsia H Siedentopf—p 1122  
Leukemoid Crisis Like Form of Remission of Pernicious Anemia  
Treated with Liver J T Brugsch and H Naegelsbach—p 1125  
Spontaneous Hypoglycemia A Wotzka—p 1127

**Prevention of Eclampsia**—Siedentopf emphasizes the significance of antepartum care in the prevention of eclampsia. He shows that regular examinations during pregnancy, particularly the control of the blood pressure and the watching for cerebral symptoms, make possible the early discovery of the women endangered by eclampsia. Conservative treatment as carried out by him consists in rest in bed, limitation of the fluid intake and a salt-free diet. In severe cases the patient receives only fruit for several days or the woman undergoes treatment by means of hunger or thirst. To facilitate the elimination of edema, magnesium sulphate is prescribed occasionally. If active treatment is resorted to, delivery is induced or accelerated. The author found that conservative treatment was effective in only slightly more than half of the cases in which it was employed. In the other cases, active treatment had to be resorted to on account of a threatening exacerbation of the symptoms. It was observed also that the conservative treatment influenced the various symptoms differently. The influence on the edemas was unusually favorable, for they nearly always disappeared rapidly. The renal symptoms reacted less promptly and the influence on the blood pressure was still more unreliable. The author rejects as unjustified the assertion that in active therapy the infant mortality is higher, for his own observations disclosed that the infant mortality was higher only when other complications existed, such as a narrow pelvis, heart disease and premature detachment of the placenta. He concludes that if in women with pre-eclampsia a trial with conservative measures proves unsuccessful active treatment should be instituted.

**Leukemoid Form of Remission of Pernicious Anemia**—Brugsch and Naegelsbach report the clinical history of a woman, aged 67, in whom a leukemoid blood crisis developed in the course of a pernicious anemia that had been subjected to liver therapy. A severe erythroblastic crisis and leukocytosis developed. The myelogenous leukocytes, up to the promyelocytes, showed toxic granulation and other pathologic changes. Myeloblasts likewise were observed. This appearance of pathologic leukocytes together with the increase in reticulocytes, the normoblastic crisis and with the further increase in the enlarged erythrocytes in the peripheral blood, is interpreted as a sort of cleansing of the bone marrow with maturation and elimination of diseased blood elements, and consequently a process of restoration. In this process of restoration, the bone marrow and the reticulo-endothelial system proved quantitatively inadequate for the maturation, denucleation and destruction of the diseased cells, and for this reason some of them were eliminated in the immature state. The authors call attention to the fact that these manifestations are of short duration and have a favorable prognosis for if liver therapy is continued they soon terminate with the appearance of normally granulated leukocytes and of erythrocytes of normal size.

**Short Wave Therapy of Brain**—Horn and his associates relate observations on ten schizophrenic patients who were subjected to short wave therapy of the brain studies on the

brains of rabbits that were subjected to treatment with short waves, and the results of histologic examinations of the brains of two patients with dementia paralytica, who had died eight and ten months after short wave therapy had been applied to their brains. The authors observed deep changes in the brain and its meninges. They admit that the clinical results of short wave therapy are still unsatisfactory in patients with schizophrenia as well as in those with dementia paralytica, but they do not deny that another dosage, perhaps irradiations at greater intervals, may eventually produce more favorable results. They emphasize that the rules laid down by Liebesny for short wave therapy must be given attention. Liebesny maintains that, in order to obtain a uniform depth action the condenser plates should be from 6 to 10 cm away from the head and not 1 or 2 cm, as was the case in most of the experiments. This rule must be followed to influence the deeper portions of the brain. Moreover, an increase in the temperature of the brain should be avoided. This may be possible by reducing the dosage.

**Injection Treatment of Hemorrhoids**—Two or three days before the injection treatment, Henninger gives a laxative, and on the evening and morning preceding the injection an enema and sitz bath are given. After careful cleansing with corrosive mercuric chloride, a 20 per cent solution of cocaine is applied as a surface anesthetic and left for from ten to fifteen minutes. Then, following renewed cleansing with corrosive mercuric chloride, the suction bell is applied to the hemorrhoids and injection is begun on the innermost row of hemorrhoids and then proceeds to the more outward ones. Up to eight nodules can be obliterated in one session. For injection into the subcutaneous nodules, into nodules that have undergone a change of some kind and into ordinary prolapses of the mucous membrane, the author recommends a dextrose-glycerin solution, for injection into nodules that are covered with mucous membrane, he recommends the same solution or the solution with an addition of 4 per cent quinine lactate. The prescription for the dextrose-glycerin solution reads: The prescription for the dextrose-glycerin solution reads: 10 per cent dextrose 20 parts, bidistilled glycerin (plus with the quinine addition) sufficient to make 100. The one needle 1 mm in thickness and beveled at the tip. After injection the nodules are replaced with the aid of gauze and which petrolatum has been applied with the tip of syringe and fifteen minutes, is given 15 drops of tincture of opium and is told to take from 10 to 15 drops of tincture of opium three times daily on the following day or two, to avoid defecation. To prevent prolapse of the injected nodules, the patient rests for of the treatment should avoid sitting. On the day following the injection the patient is usually able to work. The first defecation is generally painless. During the first week defecation should be followed by a sitz bath and the application of a petrolatum preparation. It is necessary to reexamine the patient on the fourth or sixth day to avoid postinfectious necroplasia. If all precautions are taken, the incidence of this complication which is practically the only one, can be reduced to less than 1 per cent. The permanent results of this treatment are favorable. The author discusses the indications for the injection treatment. If prolapse of the mucous membrane is caused by prolapsed hemorrhoids, injection counteracts it, but in case of a large prolapse, injection is usually ineffective. Injection is contraindicated in case of acute inflammation of a nodule and also in prolonged incarceration, but, if incarceration has undergone severe changes, injection can be done after a day or two. The injection is most effective in case of bleeding nodules and also in chronically inflamed nodules.

**Peptic Ulcer and Skin Diseases**—Bergman says that gastric ulcer is not a local disorder but the manifestation of a systemic disease. Studies in 100 cases convinced him that itching skin diseases are a frequent occurrence in patients with ulcers of the stomach or the intestine. The predisposition to catarrhs, which characterizes the mucous membranes of patients with vasoneurosis and thus also of the ulcer patients involves likewise the skin of these patients. In calling attention to a certain parallelism between changes on the external and internal (gastro-intestinal tract) body surfaces the author

suggests the possibility of a similarity between ulcer gastritis and certain skin diseases. He shows that, if the gastritis of ulcer is considered an "entodermatosis," several obscure factors in the pathogenesis of ulcer become clearer.

### Zentralblatt für Gynäkologie, Leipzig

58 1745 1808 (July 28) 1934

New Methods of Trichomonis Therapy A. Hochloff —p 1775  
Experiences with Belladonna Suppositories in Obstetrics O. Weinstock —p 1776

**Ammonia in Eclampsia**—Llusia states that pregnancy is characterized by a slight hyperammonemia, which is more pronounced in preeclampsia and still more in eclampsia and is greatest during the convulsions. The uremia is reduced to the same extent as the ammonia is increased, so that the quotient ammonia-urea is greater. After delivery the ammonia content decreases and the urea content increases to normal values. In cases of puerperal eclampsia, however, these values do not change until after the attacks of convulsions cease. The cause of the hyperammonemia is the functional inadequacy of the liver, but there is evidently no renal retention of ammonia. Pregnancy is characterized by a slight hyperacidity, which increases during preeclampsia and eclampsia. The mother substance of ammonia is decreased during preeclampsia and eclampsia, so that the potential ammonia values are smaller and nearly all the ammonia exists in the actual state. A considerable portion of ammonia enters the fetal circulation and is changed by the fetus into urea. The placenta does not take part in the ammonia regulation of the fetal circulation, and in the ammonia formation it seems likewise of no significance. In view of the degree of concentration of the ammonia in the blood as well as in the cerebrospinal fluid which exists during the eclamptic convulsions, it may be assumed that the toxic action of the ammonia is responsible for the convulsions. The other symptoms of eclampsia, however, seem to have no connection with the quantities of ammonia.

### Finska Lakaresällskapets Handlingar, Helsingfors

76 587 684 (July) 1934

- \*Lymphogranulomatosis Clinical Observations E. Adlercreutz —p 587

**Lymphogranulomatosis**—Adlercreutz reports thirty cases (seventeen in men and thirteen in women) of histologically examined lymphogranulomatosis treated from 1915 to 1933. Tuberculosis was present in five cases. In twenty cases the onset of the disorder was indicated by swelling of the lymph nodes, in seven the swelling seems to have appeared in a later stage, and in three the lymphoma was not observed by the patient before admission. Pruritus occurred in nine cases and pigmentation of the skin in six. Two cases presented marked symptoms from the spinal cord. There were abdominal pain and diarrhea in eleven, enlarged abdominal lymph nodes in six, splenomegaly in nineteen and hepatomegaly in seventeen. Before the beginning of treatment on admission, the red blood picture was normal in six cases, there was slight anemia in nineteen and grave hypochromic anemia in five. The sedimentation reaction, done in nineteen cases, showed increased values, often marked. Leukocytosis, usually moderate, was found in nineteen cases, neutrophilia in twenty, eosinophilia in only one and monocytosis in two. Lymphopenia appeared in twenty-four cases. The lymphogranulomatosis cases are classified on the basis of temperature into cases showing slow relatively 'benign' progression and cases showing rapid more malignant development. Thirteen of these cases, mostly in older persons, presented an afebrile or subfebrile course, and seventeen, mainly in younger persons, greatly increased temperature, usually of Pel-Ebstein type. The 'cardinal symptoms' of the disease being more often represented in the second group. The total duration of the disorder in eighteen cases showed a maximum of eight years in one instance, only four patients lived more than three years. Complications were frequent. Certain diagnosis can be made only on histologic examination of excised material. Roentgen treatment was given in all but

one case. The anemia was seldom affected by the therapy, the total number of leukocytes was reduced after each series of irradiations, but only slight changes resulted in the relative frequency of the different white blood elements.

- \*II Experimental Investigations on Effect of Corpus Luteum Extract on Mammary of Infantile Guinea Pigs E. Dahl Iversen —p 821

**Effect of Corpus Luteum Extract on Mammary of Infantile Guinea-Pigs**—Dahl-Iversen found that, in infantile uncastrated female guinea-pigs, corpus luteum extract produces a physiologic growth of the mammary glands, which is however, slight in comparison to that caused by estrogenic substance under similar conditions. The secretion noted in the glandular tubes after the administration of corpus luteum extract, as after the administration of estrogenic substance, is thought possibly to depend on an admixture of estrogenic substance in the corpus luteum extract.

**Acute Polyarthritus**—Motzfeldt found that, of 10,000 patients treated in the medical division of Aker Hospital from 1924 to 1933, 615 had rheumatic diseases, 140 of these, or 14 per cent of the entire number, suffered from rheumatic fever. There was a history of previous rheumatic fever in forty-eight cases, or 34 per cent. Complicating recent endocarditis was found in twenty-two, or 157 per cent. Pericarditis occurred only four times and was responsible for the only fatal case. The author states that in sixty-two cases there was a direct, undoubted connection between tonsillitis and the rheumatic fever. In ten the disorder followed a catarrhal infection without tonsillitis, and in about half of the cases the rheumatic fever was primary. Six patients had previously been tonsillectomized. Control of all cases by the sedimentation reaction was introduced in 1926. In 80 per cent of the ninety-three patients treated since then the sedimentation reaction was more than 50, frequently a sedimentation reaction of more than 100 was seen in patients with normal rectal temperature. With normal sedimentation values rheumatic fever may with certainty be excluded. Since 1926 the hospital stay has been lengthened to an average of nine weeks instead of six, as formerly. Rest in bed until all signs of activity have disappeared is regarded as the most important part of the treatment. In most cases salicylate is given the daily dose as a rule not exceeding 5 Gm. No specific action is ascribed to salicylates.

**The Heart in Diabetes**—Electrographic studies in fifty-five diabetic cases treated during the last two years showed normal electrograms in only twelve. During treatment of the diabetes, fourteen readings became normal and six approached the normal. Of ten patients admitted in diabetic coma, only one had a normal electrocardiogram. Klingenberg concludes that in diabetes with pathologic metabolism definite signs of myocardopathy are often seen and the best therapy of the diabetic heart is treatment of the diabetes.

**Second Attack of Poliomyelitis After Twenty-Four Years**—Tesdal says that the first attack at the age of 14 resulted in paralysis of the lower extremities, the second, at 40, was followed by paralysis of the arms. The diagnosis was each time supported by the typical course and the results of examination of the spinal fluid and was verified by a neurologist. Twelve certain cases of second poliomyelitis infection have been reported in the literature.
